By substituting a mercury break for the vibrating spring contact-breaker it is possible to get single discharges, the primary circuit being made and broken by hand. When these single discharges are recorded upon the moving surface it is found that the "make" tracing does not exhibit the abrupt short character shown in Fig. 3, but is longer and tapers away like the "break" discharges of Fig. 2. This led me to suppose that the "make" discharge was cut short by the next succeeding "break" discharge, and in order to settle this point a tracing was taken with two needles at once, one for each pole; it was then clear that the break discharge followed closely upon the make discharge without any perceptible interval at all. The character of the tracing given by both poles writing side by side (Fig. 5.) is interesting. It was drawn by hand on a slip of paper, and gives a good general idea of the relations in time of the make and break discharges. It also explained why the "make" discharges had a shorter duration than the break. No doubt the character of the tracings depends a good deal upon the contact-breaker used. Some of these make a large excursion and leave the primary circuit open for a comparatively long time while with others the primary is kept closed for a comparatively long time before it is broken again. The contact-breaker of the coil used in these experiments has a short and stiff spring and makes very brief contacts.

The tracings of Fig. 2 show that the current at break of an induction coil discharging through a resistance of about 1,000 ohms may last as long as one-eightieth of a second. The shorter duration of the make discharge in the coil used is due to the fact that it is cut short by the establishment of a "break" current in the opposite direction.

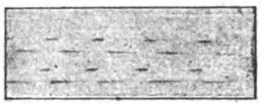

Fig. 5.—"Make" and "Break" (Positive) Discharges. To be read from left to right.

No sign of oscillation, or more correctly, no sign of alternation, can be seen in these tracings. In *The Electrician* (London) for December 25, 1891, is an abstract of a Paper on the Induction Coil, by M. Colley, with figures of vacuum tube discharges as seen in a rapidly revolving mirror, and with curves to represent the oscillations of the discharge; though showing large oscillations, the curves do not show alternations or changes of sign. If such had been present in my experiments the tracings should have shown them as gaps in the length of each small mark.

I should have been glad to supplement this communication with some notes on the effect on the tracings of putting a vacuum tube in the circuit; but I have not yet been able to get any satisfactory results, for the vacuum tube diminishes the current so greatly that the tracings become very faint, and the iodide of potassium paper sometimes behaves capriciously; however, a vacuum tube does seem to shorten the duration of the discharge considerably.

Tracings of smaller medical coils are essentially the same as those of the one used, the main difference is that the make marks are longer, if the contact-breaker is less rigid and more springy.

Austrian Delegates to the Electrical Congress.

The Electrotechnischer Verein of Vienna has appointed the following of its members delegates to represent it at the World's Electrical Congress which convenes in Chicago August 21: Nikola Tesla, A. Prosch, Inspector of the Austrian State Railways; Ernest Egger, Dr. Johann Sahulka, Constructor at the Imperial High School, Vienna; Fred. W. Tischendörfer, and Joseph Wetzler.

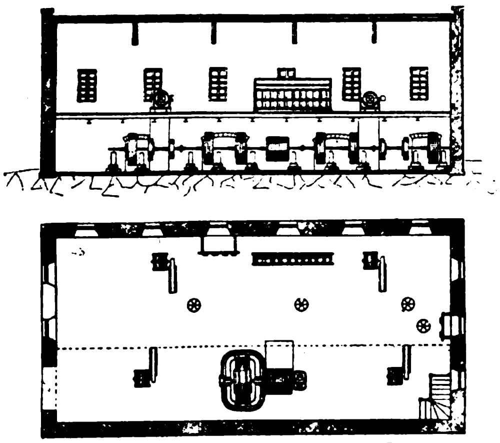
[†] No. 3 was reduced a little too much in the camera.

The Guadalajara Electric-Light Installation.*

BY RAFAEL M. DE AROZARENA.

Among the industrial enterprises taken up in Mexico by local capital, the plant for the supply of the electric light and power in the City of Guadalajara, Jalisco, is one of the most notable, not merely because of its magnitude with respect to the investment required, but also because the project necessitated the use of novel and special machinery, the source of supply being located 17 miles from the base of demand.

The problem was to install at the falls of Juanacatlán (the Niagara of Mexico) a hydraulic and electric plant which should be capable of supplying in the city of Guadalajara—distance 17 miles—sufficient electric energy to operate some 950 H. P. in the form of light, divided up as follows: seven thousand five hundred incandescent lights of 16 candle-power each and 200 arc lights of 2,000 candle-power each.



LONGITUDINAL AND HORIZONTAL SECTIONS.

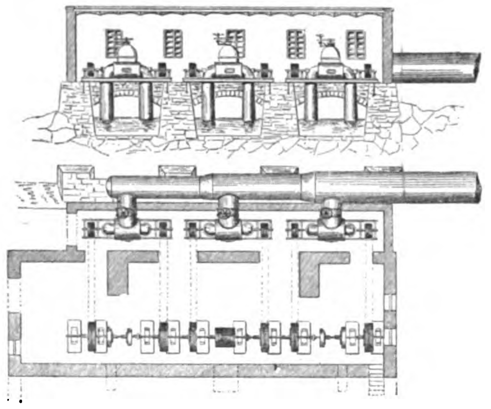
After careful consideration and study, the plans were projected and machinery ordered from the following well-known houses: the electric machinery and material from the Thomson-Houston International Electric Company, of Boston, Mass.; the turbines and piping from James Leffel & Company, of Springfield, O.; the valves from the Ludlow Valve Manufacturing Company; the countershaft, clutches, pulleys and bearings from the Hill Clutch Company, of Cleveland, O.; and the iron poles for carrying the wire on the main line from the falls to the city—a distance of 16 miles—as well as for the wires in the city, from the Reading Iron Company, of Reading, Pa.

The falls of Juanacatlán are on the Grande River, and situated some 17 miles (28 km.) southeast from the city of Guadalajara. The whole volume of the river falls at this point some 58 ft. in a perpendicular line, with the shores above the falls sloping gently to the stream. Below the falls the shores on both sides slope almost at an angle of 45°, leaving but little room at the bottom upon which a building could be erected, for which reason the building was projected of three stories, as shown by the section of Drawing No. 1.

The work above the falls was simple and of easy execution, for, the river being very wide at this point, its depth is small, and a masonry wall some 3 ft. high was built, running across the river for two-thirds of its width and at an angle of 45° to the line of the falls, the object of which was to carry the greater part of the water in the river to a given point on its left bank directly at the falls; then a raceway was formed 14 ft. high by 14 ft. wide, from which the 7-ft. diameter conduit pipe carried the water down to the turbines. This conduit pipe is made of wrought-iron sheets ¼ in. diameter, riveted together, no flanges being used. At the head of the pipe is located a vent pipe, to protect the pipe from collapsing when the wooden gate which is located at its entrance is closed. The pipe, to conform to the nature of the fall at this point, has two elbows of 90° and one of 45°, from which on a horizontal line it connects the three turbines together, reducing its diameter from 7 to 6 ft. between the first and second turbine, and from 6 to 5 ft. between the second and third turbine. Directly in line with the piping are located the three horizontal double Leffel turbines, and between the turbines and the conduit pipe in the connecting pipes, which are 4 ft. 6 in. diameter each, are located Ludlow straightway gate valves, which are opened and shut by geared hand wheels, thereby permitting the water to be closed off from each or any of the turbines without having to stop the others.

The turbines located on the first floor of the building are horizontal double wheels, placed in one case; both wheels are connected directly on to the same shaft, which extends out from the case on both sides, and has at each end a sheave pulley for transmitting the power. Each turbine is 20 ins. diameter, and has its independent draft tube; and as the river is known to rise in the rainy season from 1 to 2 m., the turbines were placed 16 ft. above the bed of the river, with draft tubes, all 10 ft. long, discharging into a well 4 ins. deep (which is the average depth of the river in the dry season), making the distance from the center of the turbines to the surface of constant water in the tailrace exactly 12 ins. This mode of setting turbines with draft tubes has given the writer excellent results here in Mexico.

The power of each set of turbines is 550 H. P., making a total of 1,650 H. P. The power is transmitted from the turbines to a countershaft placed in the second floor of the building. A rope driver is used, of endless manilla, plumbago, tallow-laid rope, 1 in. diameter, using an idler pulley on a stress car, with weight. Each pulley has 15 groves to receive the 15 strands of rope.



SECTION AND PLAN OF TURBINES AND COUNTERSHAFT.

The 42-in. diameter pulleys on the turbines connect with clutch pulleys on the countershaft of 84 ins. diameter, giving a speed of 6,594 ft. per minute to the rope. This driver, when the speed does not exceed 7,500 ft. per minute, by using sheaves at least 40 times the diameter of the rope, the writer has found to be very satisfactory, and on account of its duration much cheaper than belt drivers, especially for damp places.

In Orizaba, over two years ago, the writer used this driver for transmitting 188 H. P., for electric-light work; the rope, which to-day shows no signs of wear, is the same one which has been used from the start, and the plant has run on an average 11 hours every night, without any interruption. Great care must be taken, however, not to put too much weight on the stress car which carries the idler pulley.

Arc-Lighting Dynamos.—For furnishing current to operate the arc lights, the familiar Thomson-Houston "M. D." dynamos were employed. They have capacity each for 50 arc lights of 2,000 candle-power, or, in other words, a rated output of 25 kilowatts. The current strength is 10 amperes and consequently the maximum voltage 2,500.

The dynamos weigh 3 tons each, require floor space of about 15 sq. ft., a belt speed of 3,868 ft. per minute, with a consumption of nearly 50 H. P. under full load. Four such dynamos are in use, operated two in "series" to avoid multiplicity of wire. Thus, for a total capacity of 200 lights, only two circuits leave the generating station. Each dynamo is supplied with the usual ingenious and efficient "automatic regulator and controller," without which it would be well-nigh impossible to fulfil the condition. With such, however, lamps may be lighted or extinguished without the necessity of paying attention to the dynamo.

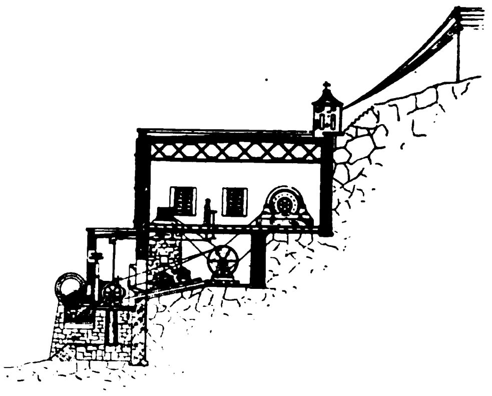
Arc Circuits.—The current is conveyed from the dynamos by means of highly insulated copper wires to a slate switchboard arranged for any desired combination of machines; from here through current indicators to the lightning arresters, from which the wires are led to the pole line. The pressure utilized being rather above the safe limit, the insulation of the circuit is augmented by fastening the wires upon oil insulators, mounted upon wooden cross-arms. The construction of these insulators is such that leakage is practically prevented, as, in order to escape by leakage, it would be necessary for the electricity not only to overcome the wire insulation, but also to pass through two strata of oil, the insulating qualities of which are well known.

In the city of Guadalajara these circuits are led to a central distributing station, in which is placed a duplicate plant of lightning arresters, switchboards and testing instruments. It is from this station that the lights are directly controlled.

Arc Lamps. — Standard double carbon arc lamps are used throughout the city. They are suspended from steel cables stretched from corner to corner, supported by house structures arranged with pulleys and cables so that the renewal of carbons may be readily attended to.

Incandescent Dynamos.—As but one dynamo was desired for this installation, one of special construction was supplied. It is of the alternating current type, has 40 pole pieces, and yields approximately 350 amperes at 1,000 volts, or, say, 350 kilowatts.

The dynamo weighs between 30 and 40 tons, requires a floor space of 216 sq. ft. and a belt speed of 6,024 ft. per minute, consuming, under full load, some 750 H. P. The armature is run at the low speed of but 300 revolutions per minute, and the shaft, which is 9 ins. in diameter, is furnished with a 60-in. diameter pulley, having 28 grooves for 1¼-in. rope, as this dynamo is driven from the countershaft with a rope driver the same as between the turbines and the countershaft. The 40 pole pieces forming the field magnets are excited by means of a separate exciter known as "D-5," and having an output of 5 kilowatts at 125 volts.



CROSS-SECTION OF STATION.

Various indicating instruments are installed, enabling the operator to tell at a glance what load is upon either machine and at what pressure the dynamos are operating. To convey with moderate loss so great a current as 350 amperes over a distance of 17 miles would require a copper wire having a sectional area of about 4 sq. ins. Such a conductor could not be used, for practical reasons, to say nothing of the expense, which would be itself prohibitive. As the proper section of copper wires varies directly with the current it is necessary to carry, it is obvious that, in order to transmit such power over a wire of moderate size, the quantity of current must be reduced. Without changing the quantity of wire this may be done by increasing the voltage, which, accordingly, was raised to a maximum of 5,000, thus reducing the current to about 70 amperes, and the size of the wire to one having a sectional area of .1662 in.

---

* Read before the International Engineering Congress of the Columbian Exposition, 1893.

Step-Up Transformers.—To so increase the voltage from 1,000 to 5,000, a bank of 10 step-up transformers was installed. These are built upon the lines of the type "F" oil transformer manufactured by the General Electric Company. They transform the energy of the dynamo at an efficiency of about 98 per cent., delivering to the line, therefore, 98 per cent. of the energy supplied them and at five times the pressure. The transformers are so designed as to be filled with oil, the insulating qualities of which are very high, thereby increasing the insulation resistance of the transformer, rendering it less subject to damage from lightning discharges, and, indeed, restoring the insulation, should it be destroyed by means of a stroke of lightning. The transformers are banked or operated in multiple. They have a capacity of 30 kilowatts each, weigh approximately 1,300 lbs., each requiring 12 cu. ft. of space. They are protected by a simple but effective system of circuit breakers and fuse connections, and the current passing from them is carried through a special lightning arrester designed to protect circuits of extraordinary high potential.

Main Circuit.—The cross-arms, pins and insulators used in connection with the alternating circuit are precisely the same as those described under the heading "Arc Circuits."

Step-Down Transformers.—The high potential incandescent line carried to the central station in the city of Guadalajara is passed through lightning arresters and safety devices, as described above, to the bank of step down transformers, which reduces the pressure to 1,000 volts, at which potential it is carried through the streets of Guadalajara as in ordinary installations. In the Guadalajara Central Station switchboards are installed, enabling any combination of lights and circuits to be made, without attention to the dynamos at the point of generation. The number of lights in operation, the physical conditions of the circuits, and indeed the conditions of the dynamos at the generating station, can all be determined in Guadalajara. Telephonic communication is established between the two stations, enabling those in charge to give their directions promptly.

As a further protection against lightning, which in the State of Jalisco is very severe, iron poles have been used, each surmounted by a pointed lightning arrester rising some 3 ft. above the top of the pole, or, say, 5 ft. from the highest current conveying wire. These arresters are, of course, mechanically connected to the iron poles, besides which they are joined to each other by means of an iron wire. This is considered the most effective protection possible, as it produces an artificial earth above the wires conveying the electrical current.

The plant of the National Electric Manufacturing Company of Eau Claire, Wis., under an order of court is to be sold by the receiver, Mr. Ralph E. Rust, on September 4.

The Inventor of Gutta-Percha-Covered Wire.

Mrs. E. H. Danchell, in a recent letter to the *Engineer* on this subject, gives the following facts: "On March 19, 1845, Mr. F. Wishaw, the secretary of the Society of Arts, England, read a paper upon gutta-percha before that society, and exhibited specimens of that material in the raw state, and moulded into various shapes by himself. This, then, was probably the occasion at which both Mr. William Siemens and Mr. Danchell obtained samples, and the former sent it to his brother, Mr. E. W. Siemens, at Berlin, while my husband at once conceived the idea of applying it as an insulating material for telegraph wires, and succeeded in doing this, and then started for Berlin. My husband thus spent money, time and brains, and solved the problem, while no statement is forthcoming of Mr. E. W. Siemens having done so till 1847. It appears that gutta-percha already then, that is in 1845, through a Dr. Montgomerie, of Singapore, had become known to a few in London, for there are the following British patents at this time, viz.: Brooman, dated March 11th, 1845, No. 10,550, for preparing gutta-percha by purifying, masticating, and mixing it with sulphur, rubber, French chalk, etc. Brooman, dated March 27, 1845, No. 10,582, for making it into thread. Nickels, May 20, 1845, No. 10,673, for applying it to book covers, writing cases, etc. Bewley, dated September 4, 1845, No. 10,825, for molding and pressing it into various shapes, also for lapping it in strips round a core, the edges being joined by heat or solution. His patent specification shows a cylinder with piston and steam-heated die box; the gutta-percha being pressed through it and around a core bar, or wire, thus coating the wire. He also describes another apparatus for doing the same thing, viz., by means of grooved rolls and a core. His final specification was filed on February 22, 1846. Between March 11, 1845, the date of Brooman's above-named patent No. 10,550, and April 23, 1850, the date when Mr. E. W. Siemens applied for his patent for an improved machine for covering telegraph wires—forming, in fact, an improvement upon Bewley's patent No. 10,825, of September 4, 1845—there are over fifty British patents for treating and applying gutta-percha to a great many purposes, and amongst them is one by Ricardo, No. 12,262, of 1848, for covering telegraph wires with gutta-percha, and one by Barlow and Forster, No. 12,136, of 1848, for the same purpose."

The "Earth" Question.

The Report of the Committee.

A few weeks ago we published an account, sent by our London correspondent, of the evidence elicited during the sitting of the Joint Committee of Lords and Commons, which committee, it will be remembered, was appointed solely for the purpose of studying the important question that had arisen between the Telephone Company and the Electric Tramway and Railway Company regarding the "earth."

The report of the committee, which sat for eight days, has now been made public. The main tenor of it is that in the present state of electrical science it is not desirable to insist upon electrical tramways using an insulated return conductor, and that to impose such a condition would interfere with the development of electric traction. The committee, however, recommend that the Board of Trade shall have power to make regulations to secure the best system of working electric tramways and railways, regard being had to the cost of carrying out such regulations and their effect upon the commercial prospects of the undertaking. The committee state that they regard with apprehension a large extension of the system of overhead wires in crowded centres, and recommend that statutory powers be granted to enable telephone companies to lay their wires underground.

The Light of the Electric Arc.

At a meeting of the International Society of Electricians, on the 7th ult., M. Violle described the experiments which he had been making on the electric arc. This experimenter has found that the light intensity of the positive carbon remains sensibly constant when the power supplied is varied in the proportion of 1 to 60. He has employed two methods of measurement, that of the spectrophotometer, the accuracy of which is really much greater than is usually stated to be the case, and a second method due to Arago employing interference fringes. M. Violle exhibited a number of photographs of arcs of different candle power, in order to show the constancy of the intensity of the positive carbon. By measuring the opacity of the negative plates, these photographs could be used as a gauge of the intensity. M. Violle recalled that this phenomenon had already been investigated by Rosetti, as well as by Capt. Abney and Silvanus Thompson; and everyone had attributed it to vaporization of the carbon. This opinion was perfectly justified, for the deposit on the negative carbon has the appearance of having been condensed from vapor, and M. Violle has actually been able to produce crystals on this part. A photograph of an arc produced between carbons of purified retort carbon was shown, and it exhibited a very curious appearance. Despretz had also observed that the phenomenon was due to volatilization, but that there was fusion or more or less softening of the carbon; he had also attributed the deposit of carbon, which is formed in the arc, to the condensation of vapor of carbon, but he was unable to elucidate the question because he used impure carbons. M. Blondel has recently recognized that impurities in the carbon have not, in practice, any sensible effect on the intensity, which remains constant with carbons of very different quality. The intensity of the arc, he thought, was therefore a constant, and it might be utilized as such. M. Violle stated, in conclusion, that the temperature of 3,500° C., which is given for the arc, ought to be considered as a provisional value, although the true temperature is probably but little different from this figure.

The St. Louis Consolidation.

As predicted exclusively in Electricity some weeks ago, the consolidation of the Missouri Electric Lighting and Power Company and the Municipal Electric Lighting and Power Company at St. Louis is now announced. The incandescent service will be from the plant of the former company, and the arc service from the latter. An effort will be made to secure a more favorable contract with the city, the present one having proved unprofitable; at the present rate, it is said, there would be a further loss of over $100,000 in the contract.

The Edison Illuminating Company of St. Louis, a paper company, organized by local capitalists, and whose capital stock has been increased within a year from $5,000 to $4,000,000, is understood to have arranged the deal, and eventually the consolidated companies will be united under the name of the Edison Company.

Judge Harlan has signed an order authorizing Morrill N. Packard, trustee for the Southern Electric Company, to carry out all the contracts already made. The order was signed on a petition presented by the trustee and the creditors.

ELECTRICITY.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.
Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

English Patent Law. In view of the expiration of the Edison lamp patent in England in November next, the English manufacturers are beginning to interest themselves in this subject, which heretofore has been totally ignored owing to the law which prevails in that country forbidding even experimental work on patented articles. As a result of this the makers of incandescent lamps will enter into this branch of business entirely devoid of any practical experience, and it will probably require a long period of experimental work to put them in a position to compete with the present makers.

The law prohibiting experimental work appears to us to be a most effective barrier to research and progress in invention and one that reacts as unfavorably upon inventors generally as upon the public; and where, as in the lamp business, the details of the process of manufacture can be kept more or less secret, the monopoly which a patent secures to an inventor may be extended much beyond the limit of its legal existence. In this case the public will start in with the same knowledge that the present company started with at the time the patent was granted, and gain the necessary experience during a time when the business is open to all. This time must be more or less wasted in arranging and perfecting details which on this side of the water are well known, and which inure to the public benefit immediately on the expiration of a patent.

……o……

Electric Traction Regulations. The English Parliamentary Committee which has lately been considering the question of earth returns for electric railways in relation to telegraphic and telephonic disturbances, has made a report which, on the whole, is decidedly favorable to the railway interests, and has framed a clause to be inserted in all franchises providing for the use of heavy currents except those for electric lighting.

From the summary of this report, printed elsewhere, it will be seen that it is in the nature of a victory for the traction interests, and it is generally commended by the technical press, which predicts an era of electric railway progress as a consequence of the removal of the restrictive measures which have so far checked any material advance in this direction in England.

The report takes the same view that the courts in this country have generally held in regard to telephone disturbances, and declares that in the light of present experience it is inadvisable to insist on insulated returns for railway circuits, and that there is moreover sufficient reason for recommending double telephone circuits, as the evidence submitted showed that this plan not only improved the service but in many cases was already being adopted.

……o……

ELECTRICAL men throughout the country, and especially readers of ELECTRICITY, will no doubt be interested in knowing more about the Hon. H. S. Pingree, Mayor of Detroit. They will find a full page sketch of this pugnacious and level-headed gentleman, with portrait, in the New York *Tribune* of Sunday, August 6.

The Smaller Stockholders Frozen Out. On Friday, July 28, the opinion was general in Wall Street that the Electric Trust would be in serious difficulty within twenty-four hours. The directors were in session nearly all day, and after the close of business on the Exchange gave out the notice which was printed in our last issue, that a syndicate had agreed to take treasury securities to an amount to net the company $4,500,000, which would pay off the floating debt. It was also announced that the stockholders would have the preference in the offer of these securities.

The statement was brief, and almost unintelligible, but it answered the purpose in that it showed that a receivership had been averted. The stock went up a little, and the newspaper critics suspended judgment.

Further details of the scheme are now at hand, which are almost worthy of the fertile brain of Henry S. Ives or of Jay Gould in the early seventies. When these latter gentlemen, however, carried out schemes like this, they were publicly branded as "gutting the treasury"; in the case of General Electric and its ancient and honorable Board of Directors it is called "providing for the floating debt," which means, we suppose, merchandise bills, running expenses and money borrowed to pay dividends.

It is asserted by the insiders that these treasury securities are a bargain at the price, and that the Tramway and Illuminating Company will make a good thing.

Hence we suspect that it is again intended to humbug the public, and "let them in" on the good thing.

From all the knowledge we have of these securities they seem to be the tail-ends of cats and dogs—stocks and bonds which could not be worked into T.-H. trusts, United Securities Company's bonds nor Electrical Corporation's bonds—securities which no bank would take as collateral even before the stringency. We suppose, for instance, that the remainder of the Syracuse bonds are included, and the bonds of the Pueblo company—the company which the General Electric Company had to buy outright to protect its $175,000 of second mortgage bonds, and which is losing at the rate of $20,000 a year.

Such we believe to be the quality of the "bargains" which have been taken over by the new financing company. However, until the attempt is made to sell Tramway and Illuminating Company's stock to the *public*, it may truly be claimed that it is none of the public's business what the stocks and bonds consist of.

But whatever their value, the method of disposal of these securities is unfair to those of the stockholders in General Electric who have not ready money to invest in anything just now.

Early in the year 1892 the stock and bonds of the General Electric Company were listed on the New York Stock Exchange. The company filed a sworn statement of assets in which were included a large part of these treasury securities just sold.

The stock was industriously boomed by subsidized brokers and by the Press Agent. It was represented that the company was earning 17 per cent. on its capital, and all the way from 150 to 200 was talked of as the price which the shares would reach in 1893. The public bought largely, at from 100 to 119.

After eight months of business, during which quarterly dividends of 2 per cent. had been paid, the company put forth its first regular statement, showing as treasury assets stocks and bonds of local companies (not manufacturing companies) valued at about $10,500,000. The dividend was still maintained, and stock was still bought by the public.

It is fair to assume that these purchasers supposed they were buying stock in a company honestly earning an 8 per cent. dividend and a small surplus besides, as shown by the statement, and *that each share of stock bought carried with it pro rata ownership in the assets of the company, including these treasury securities.*

Now they are politely informed that the exigencies of the situation demand the sale of these treasury securities, and that a new company, composed chiefly of the wealthiest members of the directory, has agreed to buy the most of them.

The stockholders of moderate means will, of course, be unable at this time to avail themselves of the offer of the Board, and it is only the insiders who can embrace the opportunity.

The money realized goes into the treasury, true enough, but not to extend the business ; simply to pay a floating debt, which, if the statements made at the time the public bought stock had been true, would not have existed at all.

The company has been saved from wreck, and we are ready to believe that the scheme, under the circumstances, was best for all concerned.

But the fact remains, and cannot be buried under a volume of argument or official statements, that if the public had had before them from June 1, 1892, to January 1, 1893, a complete and honest statement of the condition of the General Electric Company, they would not have been in it at all, and would not have lost their money.

The Boston *Herald* is correct in its assertion that "It is to be regretted that the General Electric Company was ever organized." It is regretted by every man in the electrical trade, by the public who bought stock, and without doubt by all the leading organizers of the company, even Mr. Coffin himself.

……

The query why more central stations do not pay has been often raised. There are several reasons, the chief of which is suggested by the tabulated statement printed elsewhere, showing how the Thomson-Houston Company was able to utilize the securities of various local companies, taken usually as a bonus after receiving ample cash for its apparatus at a reasonable valuation. Central station companies that went into business by paying cash for their apparatus and bonding themselves for two or three times their value, giving 30 or 40 per cent. of the bonds for an alleged "patent license" which has proved a delusion and a fraud, are not likely to pay in this generation. By reading between the lines of the table referred to some central station men can see why their stations do not pay.

Judge Lacombe's Interpretation of the Law. A curious misstatement of fact has gone forth in a press dispatch from New York in regard to the remarks made by Judge Lacombe when the case of the Edison Electric Light Company vs. the Mount Morris and United Electric Light and Power Companies came up before him last week. The dispatch was headed "A Setback for the Edison Company," etc., and was wholly incorrect. Mr. Elihu Root, leading counsel for one of the defendant companies, had gone out of town for the summer, and at the urgent request of Mr. Clarke and Mr. Cravath, counsel respectively for the two defendant companies, Judge Lacombe, under protest, granted an adjournment till after August 15, allowing the Mount Morris Company time to engage new counsel in place of Mr. Root, if necessary. A reference to Judge Lacombe's remarks, printed elsewhere, shows that there has been no change since last December in his opinion of the rights of the owners of the Edison patent. They can sell lamps to whom they choose, or they can refuse to sell or to manufacture any lamps at all if they see fit, under the law as interpreted by Judge Lacombe.

……

The Bears are not Omnipotent. The Wall Street "bears" have come in for a great deal of newspaper comment of late, some of it of a rather uncomplimentary character. They are accused by some silly writers of being wholly responsible for the present demoralized condition of the market for all securities.

These writers appear to lose sight of the fact that no broker can persist for a great while in selling stock which he cannot deliver. In other words, no bear raid can be successful unless the actual holders sell the stock. General Electric has not been forced down by the bears; it went lower and lower because there were more people who wanted to sell it than there were who wanted to buy at any price. It is worthy of note that these bears some time ago decided not to speculate in New York Edison Illuminating. One or two raids were attempted, but the actual stock was not forthcoming, and they lost money on their ventures.

It looks to an outsider as if the power of the bears was greatly over-estimated. They backed their judgment that General Electric would go below 50, but if the holders of the stock had refused to sell, the bears would have been bitten, and the price would not have been lowered.

A couple of weeks ago President Sturgis read the bears a lecture on the floor of the Exchange. In so far as his remarks were directed towards the disgraceful methods of such firms as A. J. Weil & Company, whose board member has since been suspended for a year, they were well merited. But the betting of speculators ought not to have a very powerful influence in upsetting actual values, or in causing bona fide owners to sell their stock at a loss. The majority betting on a horse creates the favorite, but the favorite comes in a tail-ender as often as he does a winner; and election bets, in whatever volume, change few votes. Why should simple betting at the Stock Exchange convince the public that their securities are worth less than they cost ?

Electricity maintains that the chief cause of the wasteful shrinkage in values of sound stocks, which we are at present witnessing, is found, not in bear raids, but goes back for about a year, when the most unscrupulous operators in the Street, who had been properly subsidized by Trust officials, were booming Trust stocks by all the arts known to Wall Street to a price two to five times above their actual value, thus enabling the insiders to unload at the expense of the ignorant public.

The fall in Trust stocks cannot be considered a shrinkage in values, because the values never existed upon which to base the inflated quotations.

It will be remembered that the two operators most conspicuous in booming General Electric were Messrs. J. R. Keene and S. V. White. The former was quoted as follows in Electricity for September 14, 1892 :

> "The General Electric is earning 17 per cent. per annum on its stock. This is exclusive of stocks received by it from corporations organized at various points to do business in special lines, such as electric lighting, etc., which get the authority to use the patents owned by the General Electric Company. Its business is continually expanding and it is only a question of time when the present rate of dividend, 2 per cent. quarterly, will be increased. Any person who can buy the stock, and will hold it firmly until next year, will get a large advance, not only in the price of the stock, but in the dividend.
>
> "If there are any stocks which should claim attention at the present time they are to be found in the industrial group."

Even at this late day, we insist that Mr. Keene should be summoned before the Board of Governors, and severely reprimanded for his lying statements.

……

If Mr. Edward H. Johnson should prove to be the Coming Man, the General Electric interests would have the best wishes of the trade at large, and bitter hatred would give way to huzzahs from all directions.

……

World's Fair Photographs. Our childish contemporaries the *Electrical World* and the *Western Electrician* are wasting space in a controversy over certain photographs of the Edison tower of light which might better be devoted to other uses. The tower of light is a marvel of beauty to those who can see it lighted up, but no photograph of it could reproduce its splendors, and the photograph in question was not worth stealing, or quarreling about after it was stolen. The editors of our esteemed contemporaries might better go out behind the Electricity Building and play marbles.

But as for the conduct of the official photographer in this, as in other matters, that is another story. He is an abomination and a disgrace, whose constant abuse of his privileges, coupled with evident inability to secure decent photographs, is an outrage, not alone upon the exhibitors and the newspapers, but upon the entire public, who have a right to demand that the photographs of all the beauties of the great show should be up to the highest standard of the art, and as plentiful as possible. If the country were flooded with first-class photographs of the various features of the show, infinite pleasure and instruction would be carried to many thousands who cannot visit Chicago.

We do not know who this photographer is or what his antecedents, but from his work we judge that he is a graduate from the whitewash brigade who were employed on the grounds before the Fair opened.

……

THE infamous action of the authorities in admitting the electro-medical fakes to the Electricity Building at the Fair is attracting attention abroad. The London *Electrical Review* devotes some space to these fakes in its July 28 issue. ELECTRICITY has endeavored to make it plain to foreign visitors, and to the foreign press, that these fakes have no standing among reputable electrical people on this side, and that their admission to the building is generally recognized as an injustice to the legitimate exhibitors, and a double injustice to the manufacturers of *bona fide* electrical apparatus which is sold to reputable physicians.

……

THE editor of the financial column in the *Electrical World* is getting into the bad habit of stealing all his news from ELECTRICITY, which, of course, renders our esteemed contemporary just one week behindhand in these matters. This course is wholly unnecessary. If the young man will call at this office regularly on Monday afternoons at 6 o'clock, we will give him a fair summary of the news which we have gathered for the week. We make this offer, not for the sake of the *Electrical World* itself, but for the sake of its readers, who deserve better treatment.

……

THE United States Consul at Bangkok, in reporting the establishment of a street railroad three miles long in that city, equipped with Short apparatus, expresses the opinion that if the American electrical companies were to send competent representatives to the large cities of Asia they could secure a number of contracts similar to the one that has been so satisfactorily executed by the Cleveland firm.

……

To THE victors belong the spoils! And now is the time for independent manufacturers to hustle for contracts. Begin to hustle in the proper manner, by sending an advertising order to ELECTRICITY.

……

ELECTRICITY has been a forceful factor in the electrical business world for the past year. Send in your advertisement.

……

IT WAS a very suggestive pointer on the situation, that when the General Electric Company seemed likely to be put into the hands of a receiver within twenty-four hours, as it did a couple of weeks ago, no one in the trade had either sympathy or sorrow to express. Some fears were entertained for the immediate results to the trade at large, but it was and is the universal opinion that business will never be in a healthy or satisfactory condition till the Trust is out of the way.

……

MR. HENRY VILLARD is probably the only one of the leading spirits in the organization of the General Electric Company who is unmoved by passing events. He sold out above par.

THE Association of Edison Illuminating Companies meets in Chicago this week. There has in the past been ample reason for the existence of this association, and it has been of untold value to its members. But it seems to us that the time will soon come when the association will deem it good judgment to go over in a body to membership in the National Electric Light Association, where they would be welcome, and where their field of usefulness may be still further extended.

……

WITH three financing companies at its service to raise the sinews of war, the Electric Trust ought to be able to carry out at least one more campaign.

A Trustful Soul.

The following questions and answers have appeared in the financial columns of the Boston *Advertiser*:

Investment Editor: Do you think anything serious is the matter with General Electric Company except the panic? I think you said once that they were likely to continue their present rate of dividend. I know that nearly all stocks have suffered, but General Electric especially. Don't you think the stock will improve when the panic passes away?

INVESTOR.

Atlantic City, N. J., July 24.

The managers of General Electric tell me they will maintain their present dividends, and they include the heaviest moneyed men in the country. Why they do not buy in the stock at present prices, all that is offered, I do not know. General Electric preferred must be an excellent purchase at these prices. Nothing can affect its dividends.

ABOVE PAR.

State Street. July 25.

Edison Gets the Credit for the Niagara Scheme.

(*Omaha Bee.*)

"Edison hopes some day to make Niagara furnish enough electric power to run every railroad train and light every town in the State of New York."

The Best Read Paper.

The largest trade paper advertiser in the United States recently concluded a personal letter to one of our constituents as follows:

"ELECTRICITY looks well and is doing yeoman's service on behalf of the manufacturer and tradesman as against combinations and trusts. It is the best read Electrical paper in the country to-day."

General Electric.

What is Said of It Nowadays.

General Electric opened at 48½ and sold at 52, but reacted to 46¾. The committee that is investigating the company's affairs will, it is said, report that the assets in the treasury are sufficient to protect the stock to the extent of at least sixty cents on the dollar; that is to say, this protection would be offered if the company was to wind up—which it has no intention of doing.—*N. Y. Mercury.*

It is to be regretted that the General Electric Company was ever organized. The separate concerns had a fine business, all they could attend to probably, and the prices of competition would likely have proved less difficult to meet than the perils of combination. It is a gigantic task at times to finance a monopoly and always difficult to manage it.—*Boston Herald.*

A recent issue of the *Electrical Engineer* of New York contains a paper and a short note on "Calculating Armatures." The title puzzled us at first, as our thoughts were carried to phenomenal "calculating boys"; but we find that this is not an announcement of a new prodigy, but merely a new method for getting out armature quantities. The method "is based on the analogy between the torque at the periphery of the armature and the pressure on the piston of a steam engine." If occult analogies can ever evolve good armature proportions, this one may do as well as another. In a similar manner we might design a flap-valve from its analogy with a five-barred gate, or an arc lamp from its analogy with the rush-light.—*Electrician*, London.

Trusts and U. S. Patents.

Keep Your Eye on This Lawsuit.

P. H. Williams, of Holland, Mich., manufacturer of spring tooth harrows, has filed suit in the United States Court at Grand Rapids against D. C. and H. C. Reed et al., of Kalamazoo, to recover $50,000 damages for interference with the business of plaintiff.

The defendants are members of the National Harrow Company and as such brought action against Williams for infringement of patent.

The suit is one in a series of like suits brought against anti-trust harrow manufacturers in all parts of the country.

The anti-trust men claim that a conspiracy has been organized, in violation of the Sherman Law of July, 1890, to ruin their business, and have appealed to the provisions of that law for protection.

Judge Lacombe's View of the Law.

[Report of Edison Illuminating Company vs. Mt. Morris Electric Light Company.]

Mr. Clarke (of defendants' counsel)—"The defendants' plant was installed prior to the decisions. The plaintiff here has gone on since that time furnishing that lamp to use in connection with that plant, but now they refuse arbitrarily——."

The Court—"He has a right to under the patent—that is what the monopoly given to him under the patent is for. A man may sell his lamps, or stop selling them, just as he pleases."

Was it the Forerunner of the Telautograph?[*]

"Copying Electric Telegraph."

[From the Civil Engineer and Architects' Journal, London England, May, 1848.]

An electric telegraph which will produce at a distant town fac-simile copies of writing applied to the instrument in London has just been invented by Mr. F. C. Bakewell. We have seen a specimen of the telegraphic writing copied from the original by a separate instrument, only connected with the other by wires in the ordinary manner. We understand that arrangements are being made to give the invention a trial at a long distance, for the purpose of adopting this mode of telegraphic communication generally if it be found as applicable between distant towns as it is at short intervals. The rapidity with which copies may be made with this instrument will far exceed the manual dexterity of the quickest writer; for the inventor expects to be able to transmit 500 words per minute. Where shorthand is employed, of course, the rapidity of transmission would be much greater; and plans and engravings may be copied by the same instrument.

[From the same journal, issued July, 1848.]

We mentioned in a former number that an electric telegraph had been invented by means of which a written communication could be copied at a distant town, so as to enable correspondents to recognize the handwriting of each other. This telegraph has during the past month had several trials between London and Slough. The results of these trials have proved that the power transmitted along the wires is quite sufficient for long distances and the copying process. Specimens of the writings copied from 400 miles of wire are exact fac-similes. Great confidence will be given to this method of communication by which messages are received in the well known handwriting of familiar correspondents. By the common method in general use there is no proof that the information received is authentic.

---

Legal Notes.

In the suits brought against the City Electric Street Railway Company of Little Rock, Ark., by certain banks for notes given by the railway company and discounted by the plaintiffs, Judge Lea has rendered a decision in favor of the plaintiffs. The answer of the defendant alleges that the officers had not been authorized to give the notes. The plaintiffs demurred to this, stating that the books of the defendant showed that this authority had been given. The Judge sustained the demurrer, and rendered judgment accordingly, holding the plaintiffs to be innocent purchasers. An appeal to the Supreme Court was granted, and the cases will go there for final settlement.

Solicitors for the General Electric Company have filed in Salem the answers to the bill in equity filed against the General Electric Company, the Thomson-Houston Electric Company, and E. Wilbur Rice, Jr., and Walter H. Knight, in the Supreme Judicial Court, at Salem, May 6, in which the plaintiff charges the defendants with bribery and instigation of theft in securing plans and blue prints from the Westinghouse Company. The answers are three in number—one for each defendant—and deny all charges, although admitting that in the possession of the company there may have been various prints of apparatus manufactured by the plaintiff, but secured in the ordinary course of business, without wrongful action on the part of the defendants.

Judge Green, of the United States Circuit Court, dismissed the suit of the Accumulator Company of Newark, N. J., against the Consolidated Electric Storage Company of Camden, for want of jurisdiction, the Faure patent having expired.

The Ansonia Electric Company of Ansonia, Conn., and Chicago, Ill., has begun suit against Hugh McMillan in the Wayne Circuit Court, Detroit, Mich., for $10,000 damages.

The Ansonia Company has also brought suit against the Detroit Electrical Works to recover on some notes given before Mr. McMillan's mortgage was foreclosed.

The cases of the Edison Electric Light Company vs. the Mt. Morris and United States Companies, which came up before Judge Lacombe on August 2, was adjourned peremptorily to be called again about September 1.

A decree has been indorsed by Judge Hunt at Cincinnati in the case of Tozier vs. the Novelty Electric Supply Manufacturing Company. The report of the receiver is confirmed, compensation fixed, and the payment of a dividend of 12½ per cent. is authorized to general creditors.

The Edison Electric Light Company has filed with the county clerk at Albany a notice of appeal from the judgment of the General Term in the matter of the taxes enforced by the State in 1889 and 1890 as the result of a suit brought by Hon. Edward Wemple, then Comptroller of the State.

The suit which the New York and New Jersey Telephone Company brought against the Metropolitan Telephone and Telegraph Company to recover $500,000 damages for breach of contract, decided some time ago by Judge O'Brien in favor of the plaintiff, has been sent to a referee who is to determine the amount of damages.

To satisfy a judgment of $600, Deputy Sheriff Louis Walters, of Queens County, has levied on the Norton Electric Light Company plant at Fresh Pond, which supplies with light the picnic parks near Ridgewood, L. I.

A bond in the sum of $200,000 has been given to the Sheriff of San Francisco for the delivery of the dynamos, motors, cars and other properties of the San Francisco and San Mateo Railway Company, seized at the instance of the Thomson-Houston Electric Company. The sureties are: Behrend Joost, $125,000; James A. Wymire, $50,000; Fabian Joost, $25,000.

More Details.

The Latest Plans to Raise Funds for the Trust.

The Illegal Abuse of U. S. Patents Will Now Proceed.

The following additional information has been gathered in regard to the sale of treasury securities announced ten days ago by the General Electric Company.

The new company to be organized on the treasury assets is to be styled the Tramway and Illuminating Trust, and capitalized for $4,500,000 ten-year debenture sixes and as much stock. The bonds may be redeemed at a premium. The trust will last ten years, or longer, at its own option.

The securities are to be selected by a committee from mortgage bonds, secured short time obligations and miscellaneous railway and illuminating securities, of the aggregate value of about $10,500,000.

It is said that on Friday, the 28th July last, the General Electric Company had $1,400,000 cash, and owed $5,000,000, including the $600,000 since paid in dividends. It had other receivables on the same date. It will receive $4,050,000 from the sale of its $10,500,000 treasury securities. This, added to $1,400,000, makes $5,450,000, set against the dividend and debt of $5,000,000. Allowing for contingencies even, this seems to provide for the floating debt and the current dividend. Future dividends are a future problem.

It is said that the Tramway and Illuminating Company receives two notes for $450,000 each, drawn by the General Electric Company, one of which is for value received, the other being a kind of bonus or reward of merit.

The Boston *Herald* presents the following interesting summary. We trust that it is free from typographical errors, and that the publisher of ELECTRICITY will not be indicted for copying it:

The proposed organization of the Tramway & Illuminating Trust renders interesting a resumé of the previous Thomson-Houston trusts or series, which have been organized upon treasury securities as a basis. Such resumé has been compiled as below:

SERIES A.

Established December, 1885.

Number of shares	5,000
Cost to shareholders per share	$80.00
Original amount in trust	451,251.40
Divided in cash	340,000.00
Divided per share in cash	68.00

This series was finally closed by last payment and distribution of proceeds from sale of securities October, 1889.

SERIES B.

Established August, 1886.

Number of shares		5,000
Cost to shareholders per share		$40.00
Original amount in trust		495,167.03
Divided in cash		265,000.00
Divided per share in cash		53.00
Remaining in hands of trustees:		
Bonds, face value	$103,000.00	
Stock, face value	1,000.00	
Cash	340.90	
Face value of securities now on hand	$104,340.90	
Per share		$20 87

SERIES C.

Established January, 1889.

Number of shares		40,000
Cost to shareholders per share		$10.00
Original amount in trust		1,263,940.22
Divided in cash		600,000.00
Divided per share in cash		15.00
Remaining in hands of trustees:		
Bonds, face value	$343,500.00	
Stocks, face value	469,400.00	
Accounts receivable and notes receivable	7,973.86	
Cash	21,350.74	
Face value of securities, etc., now on hand	$842,224.60	
Per share		$21.05

SERIES D.

Established October, 1889.

Number of shares		120,000
Cost to shareholders per share		Given as dividend
Original amount in trust		$2,416,468.27
Divided in cash		570,000 00
Divided per share in cash		4.75
Remaining in hands of trustees:		
Bonds, face value	$718,100.00	
Stock, face value	1,077,300.00	
Accounts receivable and notes receivable	83,272.02	
Cash	106,306.63	
Face value of securities, etc., now on hand	$1,984,978.65	
Per share		$16.54

It will be observed with reference to series "C" and "D" that while $600,000 in cash has been distributed among the shareholders of the former the par value of the securities originally placed in trust has only been reduced by $421,000, and that while $570,000 cash has been distributed among the shareholders of the latter the par value of the securities originally placed in the hands of the trustees has been reduced by only $432,000. The opportunities for profitable reorganizations and consolidations have operated to bring about these results.

The exceedingly profitable character of these series gives birth to a query whether the company has not sold its block of treasury securities pretty low at $4,050,000 net. Also, the query whether all shareholders should not be allowed to join the subscription upon the same terms. It is presumable that shareholders who subscribe outside the syndicate at a higher than the syndicate price will be very few, while shareholders who would join in the subscription upon the same terms as the syndicate might be considerable. Ought there to be any discrimination in favor of one set of shareholders as against another set? Ought a few wealthy shareholders to be permitted to select from the treasury assets at less than 50 cents on the dollar and organize a new concern to work off such assets for the benefit of the shareholders of that concern?

Trusts and Personal Liberty.

Combinations Must not Trample Upon the Liberty of the Individual.

(From a recent Address by David J. Brewer, Associate Justice of the United States Supreme Court.)

The proposition that the many may rule the one is carried into the daily life of the nation in a practical way to the extent that the individual is swallowed up in the mass, and the personal independence of every citizen, in all matters of contract and labor and life, is in danger of being destroyed.

The most noticeable social fact of to-day is that of the combination of capital and the organization of labor. Whatever may be the causes, and whatever may be the results, good or bad, the fact is beyond dispute that the trend of the two great industrial forces of capital and labor is along the line of consolidation and cooperation. I am not here to decry this tendency. I realize full well that only through this movement are the great material achievements of the day possible; but one thing is clear, and that is that the penalty which the nation pays for all its benefits is the growing disposition to sacrifice the individual to the mass, to make the liberty of the one something which may be ruthlessly trampled into the dust because of some supposed benefit to the many.

A capital combine may, as is claimed, produce better, cheaper and more satisfactory results in manufacture, transportation and general business; but too often the combine is not content with the voluntary co-operation of such as choose to join. It grasps at monopoly, and seeks to crush out all competition. If any individual prefers his independent business, however small, and refuses to join the combine, it proceeds to assail that business. With its accumulation of wealth, it can afford for awhile to so largely undersell as to speedily destroy it. It thus crushes or swallows the individual, and he is assaulted as though he were an outlaw. . . .

The business men are becoming the slaves of the combine, the laborers, of the trades union and organization. As against this servitude and sacrifice of individual liberty, I wish to enter my earnest protest. In every century humanity has looked forward through tears to a better day to come, and has asserted as the ideal yet to be attained the liberty of the individual. *Is it not bartering away the experiences of the past, are we not selling our birthright for a mess of pottage, when we encourage or even tolerate the domination of the combine*, when we look in silence upon the growing servitude of the individual to the organization ?

Current Items.

The British Government is anxious to give the people greater telephonic advantages than they now have of telegraphic facilities, which latter are exceptionally good. Among other projects of the British Post Office officials is one to establish at Leeds, in the very centre of England, a telephone exchange with which every large town in the United Kingdom will be connected, so that it will be possible for any town to speak with any other. It is intended that the work in the towns themselves shall be done principally by the telephone companies, but the Post Office itself will open exchanges where there are no companies.

At several places in Milwaukee, the Wisconsin Telephone Company has put in nickel-in-the-slot machines, by means of which telephones for public use can be provided without keeping an attendant in charge of them. There are slots for nickels, quarters, half dollars and dollars, so that the apparatus can be used for toll connections. Each coin when it is dropped into the machine causes a bell to ring and the sound of this bell is telephoned to the central office, where the operator is able to tell by the tone what amount has been paid, because there is a bell of different pitch for each of the slots. The machines that have been put in work very well and the operators rarely fail to distinguish by the sound of the bell how much money the man at the other end of the line has placed in the slot.

The car which is doing the welding on the street railway in Boston looks like a large freight car. It is equipped with motors to move it from place to place, and besides has a generator of 125 horse power on it which furnishes the power for the heat used in welding the rails. In doing work so quickly as it is done by this process there is a rough place left at the joint. This is smoothed away as though it were solder by an arc welder consisting of a large carbon about the size of one's arm, mounted on an immense glass handle. The rough steel places fall before it as lead, and the joint is made perfectly smooth. The old idea of allowing a space at the joints of the rails for the expansion and contraction of the steel has been done away with, for it has been found by experiment that the steel does not expand or contract much more than the ground itself.

In a recent electric road constructed in England a radical departure from American methods has been made. A trolley wire is suspended from arms projecting from steel columns; no guy wires are employed, as the steel wires are especially designed to withstand severe strains. At the corners the trolley wires, instead of following a curve of the same radius of the track, as in the American systems, is turned on an angle, the whole system depending on the flexibility of the trolley arm, or side collector, as it is called, which automatically engages the trolley wire in any position from two to twelve feet from the side of the car.

The Minneapolis *Tribune* states that a graduate of the University there, named C. W. Carter, has invented a car brake, to be controlled by electricity, which is regarded as the best device yet invented for the purpose. "The mechanism," says the paper quoted, "is extremely simple and safe, and it entirely does away with the old-time levers, being controlled on the concentric principle acting on the forward and rear wheels of the truck. Arrangements have been made for a test to be given within a few days on the electric cars of this city."

A diminutive electric fan in the office of the Department of Public Works at Pittsburg was located on a window sill, where its noise disturbed the clerks, and they placed it on a metal heater. A reporter says that the instant the current was turned on the electricity performed a clog dance, and waltzed the fan all over the heater, and at a speed that would make a Homewood flyer stand aghast. All the time the blue fluid flashed out in two-foot lengths, and the burring and whirring of the swift-revolving wheel nearly caused a stampede in the office. But relief came at last, when the machine with a mighty effort, as if to get away from the heater, danced off the side of it, and fell with a bump to the floor, bringing the circus to a close.

Dr. Bottomley before the Glasgow Phil. Society showed some photographs of bullets in motion, referred to in a paragraph in the Digest, April 15. Photographs were shown of a bullet in carbonic acid gas to show the slower speed of the air waves; others of a discharge of shot, and a bullet passing through a plate of glass, showing how the splinters are first splashed back when the bullet enters the glass, and after it has passed through it sucks them through the hole, carrying them with it and gradually depositing them. He mentions that Professor Boys has shown that the duration of a spark from a Leyden jar under certain conditions was about one-twentieth of a millionth of a second.

The French language, it appears, is better adapted to the purpose of the telephone than the English. It is stated that the large number of sibilant or hiss syllables in English renders it a less easy and accurate means of communication. Some English words are especially difficult of transmission by telephone. The word "soldier" is cited as one of these. Proper names frequently occur in the midst of an otherwise perfectly audible and intelligent conversation which the ear cannot possibly catch. These must be spelled out, involving delay.

A despatch to the N. Y. *Herald* from San Jose, Guatemala, states that direct communication over the Central and South American Telegraph Company's wires, via Galveston, was opened on the 24th July between Guatemala and the United States. The official opening took place on July 19, with great ceremony, the day being the anniversary of the opening of the railway between San Jose and Guatemala City, which occurred in 1884, and also the anniversary of the birth of the late President Rufino Barrios. The Government paid the cable company $150,000 in American gold on the day the lines were officially opened.

A profitable field is opened for men of artistic judgment and cultivated taste in the arrangement of electric lights in ball rooms, reception rooms and other apartments where decoretive effects are of value. The mobile electric glow-lamp affords advantages in illumination that were totally unattainable from stationary gas fixtures, and a talent for locating electric lamps in positions best adapted to the prevalent hues of the furniture and draperies of an apartment and to its form and dimensions so as to produce the desired effects of color and perspective, will be duly appreciated and fitly rewarded.

The Boston *Courier* suggests that since the speed of ocean steamers of the present models and method of propulsion has practically reached its limit, a new means of ocean travel might be found in submarine vessels of proper form, propelled by the trolley, with power supplied from cables laid as at present. The writer would have the vessels suspended at a depth below the reach of the waves, and thus swiftly glide along undisturbed by the storms that furrow the surface and make unaccustomed voyagers yearn for the the land. He does not submit any ideas as to ventilation, etc., convinced, perhaps, that by the time his system comes into vogue mankind will have ceased to breathe.

A Hartford (Conn.) paper, in recording the fact that the searchlights with which the Schuyler Electric Light Company are experimenting in Middletown are seen in New Britain, states that an aged couple who strongly believe in Lieut. Totten's prophetic vagaries were seen standing in their door-yard watching the lights with awe-stricken interest, taking them for indications of the beginning of the fulfilment of the Tottenistic prophecies. From their remarks, overheard by a gentleman passing, their faith in the divine origin of the flitting beams seemed complete, and when told that the lights were simply a demonstration of the power of electricity, although their awe was allayed, they were evidently not pleased to have their cherished beliefs rudely shaken by the cold facts.

It is not often that the engineering world is called upon to witness the completion of a work nearly 2,500 years after it was first projected; but such is the case with the canal through the Isthmus of Corinth. Projected 600 years before Christ, agitated again 300 years later, actually begun by the Emperor Nero, it is completed in 1893.—*American Engineer and Railroad Journal.*

Boston Notes.

There are two or more new style arc lamps about ready for being put on the market by Boston inventors and manufacturers, for which extraordinary claims are made. Should these claims be realized, it certainly seems as if we might look for a fairly complete revolution in the arc light department of electrical science.

The factories of the General Electric Company at Lynn are running only five days a week for the present, consequent upon the general business depression that prevails everywhere. This arrangement meets with the approval of the employees in general, as during the fine weather it enables them to enjoy two whole rest days a week. During July the company is reported to have booked over $1,000,000 worth of cash orders.

One of the most attractive resorts about this city is the Marine Park, City Point and Castle Island, where is situated Fort Independence, just off the point. The pier at City Point is brilliantly lighted by innumerable electric lights, while Castle Island is connected to the main land by a handsome pier, along the entire length of which are arc lights a short distance apart. The island forms one branch of the park system of Boston, and in an evening thousands of foot passengers throng these piers. They form the most striking features in Boston's beautiful harbor.

The present financial stress and consequent scarcity of work and money is seriously affecting the various seaside resorts in this neighborhood, but is in some respects telling in favor of the West End R. R. Co. In view of being unable to take their annual vacation by the sea, thousands of persons remain at home in the city and treat themselves most evenings to a long and pleasant electric car ride into the suburbs. One of the favorite rides is by way of Beacon street to Chestnut Hill Reservoir, over four miles out, through the beautiful town of Brookline. The scenery around Chestnut Hill is very fine, and the cars are taxed to the utmost to carry all the passengers. Many ride out to Newton, another beautiful city. Some of the five-cent trips thus being taken extend from nine to eleven miles, which people of moderate means don't fail to avail themselves of.

The International Trust Co., which is one of the leading banking firms in Boston, moved into its handsome new nine story building, corner of Milk and Devonshire streets, and began business there last Monday morning. The isolated electric lighting plant and the beautiful fixtures are among the most complete and artistic in New England, some very unique features having been introduced in the system of illumination.

His many friends will hear with regret of the serious illness of Col. L. W. Burnham, General Manager of the Electric Gas Lighting

Co., this city. Col. Burnham was making ready to start on a two weeks' trip to the World's Fair with his daughter when he was suddenly seized by an attack that quite prostrated him, and he is still confined to his bed. As is well known, he has worked like a Trojan for years, building up one of the most prosperous electrical firms in the country, with the result that his health has been impaired. Of late, however, he has been a good deal of his former self again, and was really feeling, as he imagined, first-class when his present sickness overtook him. He has the best wishes of all his friends for a complete and speedy recovery.

An interesting instance of the "freshness" which characterizes many of the young salesmen employed by the General Electric Company occurred a few days ago when one of these "fresh" young men walked into the office of the purchasing agent of one of the largest electric lighting companies in New England. This young man's employers, the Trust, had heard that said agent was purchasing supplies from outside firms and not from the General Electric Company; so they deputed the fresh young man to wait on this gentleman and respectfully inform him that it was his duty to purchase all his supplies from the Trust. The agent, singular to say, declined to see that his duty lay in that direction at all, and intimated to the fresh young man that his duty prompted him to do as he liked in the matter having in view his employers' best interest. Then the fresh young man desired to know where the agent was purchasing a certain line of supplies, which impertinent query roused the agent's color somewhat, and he brusquely answered the fresh young man that it was none of his d——d business to know, but so long as he could buy supplies of nearly any kind for 25 per cent. less than the General Electric Company's rates, he should continue to buy them where he chose, and the Trust and its goods and prices were at liberty to go to blazes—the quicker the better. This is a true story.

The beautiful marine resort, quaint old Marblehead, is to secure a new lease of existence by being connected with Salem, Lynn and Boston by electric railway. It is expected that cars will be running by Monday. When this system is complete the many lovely places on the north shore of Massachusetts Bay will be within easy reach of thousands of pleasure seekers.

General News.

What is Going on in the Electrical World.

Norfolk, Va.—Construction work has begun on the electric railway which is to take the place of the horse car lines.

Providence, R. I.—The new electric road through East Providence to Riverside and Crescent Park has been opened to public travel.

Hillsboro, Ill.—The city council has awarded the contract for lighting the city to the Electric Light Company. The electric light plant is nearly finished.

Watertown, Mass.—Many of the business firms in Watertown are considering the introduction of electric motors as a means of furnishing power for their business.

Binghamton, N. Y.—The bid of the General Electric Company for lighting the city for three years at 30 cents a light per night has been accepted by the common council.

Windsor, Conn.—The Eddy Electric Manufacturing Company, which recently went on to a time basis of five days per week, has made another reduction to eight hours per day.

Philadelphia.—Geo. W. Pierce, manufacturer of electrical supplies at 510 Arch street, has disappeared, leaving a number of debts unsettled. His factory will be sold by the sheriff.

Cincinnati.—The franchise for the proposed electric railway to Oakley has been awarded to the Cincinnati, Oakley & Madison Electric Railway Company for a term of twenty-five years.

Gardner, Mass.—The selectmen have granted a franchise to the Gardner Electric Street Railway Company to run a line between the several contiguous villages. The authorized capital is $75,000.

Jamestown, N. Y.—N. W. Gokey & Son have purchased a majority stock of the Jamestown Electric Light and Power Company, and will combine that plant with the plant which they have had in operation in their factory.

Bridgeport, Conn.—The Bryant Electric Company is now working on half time. The company has large orders, but on account of the dullness of the season the fulfilment of them has been postponed.

Mt. Pleasant, Pa.—The Citizens' Electric Street Railway Company, recently organized to build a line, has abandoned the enterprise because of the refusal of the borough authorities to give to the corporation the right to lay tracks in the town.

Lynn., Mass—The extension of the Wakefield & Stoneham Electric Street Railway line from Wakefield to Lynn is to be begun soon. The company has voted to increase its capital stock from $50,000 to $150,000 for the purpose of road construction.

Oneonta, N. Y.—The Oneonta Electric Light and Power Company, which not long ago had several judgments against it, has, according to a circular issued by the company, paid all these outstanding claims in full and has floated the whole of its new series of bonds.

Pottstown, Pa.—A Philadelphia syndicate has authorized the purchase of the seventy-acre farm on which are located the famous Ringing Rocks and adjoining property, with a view of building an electric railroad from Pottstown to that place and erecting there a large mountain hotel.

New Haven, Conn.—Improvements on the State street and Whitney avenue railroads are being pushed forward rapidly, and it may soon be expected to see the roads electrically equipped. The new power house will be 250x80 feet. The contract for the dynamos, etc., has been awarded.

Tiffin, Ohio.—Work on the Tiffin & Fostoria Electric Railway is progressing, and it is hoped by the president, R. W. Brown, to have the road completed next October. The road will be nearly fourteen miles long and will ultimately become a part of the proposed line from Findlay to Put-in Bay.

Albany, N. Y.—A method for lighting railroad passenger cars by electricity has been tested for some time on a New York Central car with good results, and it is thought that in a short time all the cars for the Central turned out at the West Albany shops will be equipped with the new lighting apparatus.

Carrolltown, Pa.—An electric light company has been organized at Carrolltown with a capital stock of $20,000. A number of Altoona business men are connected with the new corporation, which will furnish electric light for Carrolltown and also for the thriving towns near by—Hastings, Spangler and Bainsboro.

Mount Vernon, N. Y.—The Union Electric Railway Company, having applied to the authorities for a year's extension of time in which to complete their road in Mt. Vernon, and the common council having refused to grant the request, the road withdrew its bond for $25,000 and has retired from the field for the present.

San Francisco.—Severe tests have been made lately of the Hatch storage battery on an experimental car of the San Francisco Electrical Storage Company which are said to have convinced several electrical experts of its practical efficiency.—Despite the troubles of the San Francisco and San Mateo electric road with the Thomson-Houston Electrical Company, work on the extension to Baden is being pushed.

Brooklyn, N. Y.—The Union Elevated Railroad Company have been considering the substitution of electricity for steam as a motive power on their road.—Mayor Boody has signed the resolution passed by the board of aldermen granting franchises to the Broadway Railroad Company for over twenty miles of streets, and also approved the application of the same company to change its motive power to electricity.

Easton, Pa.—The contract for the building of the Pen Argyl, Bangor & Water Gap Electric Road has been awarded to Davis & Ludwig, of New York City. Work is to be commenced at East Bangor and pushed westward to Wind Gap, the contract calling for the completion of the line as far as Pen Argyl by Oct. 1, and that part of the line will then be put in operation. The company has decided to locate its power plant, etc., in Bangor.

Baltimore, Md.—It is understood that work will soon begin on the power-house to be built on O'Donnell's wharf by the City and Suburban Railway Company. The plant will have a capacity of 5,000 horse power and will be so arranged as to increase the horse power in the future i necessary. In a few weeks, it is said, the entire City and Suburban system will be operated with electric cars.—The three electric locomotives to haul trains through the new Baltimore and Ohio Railroad tunnel under the city of Baltimore are completed and will soon be tested.

Newark, N. J.—The Newark Passenger Railroad Company has agreed to lease its lines to the New Jersey Traction Company. The latter company is building a second road from Jersey City to Newark along the old Newark turnpike.—The transfer of the franchises of the Newark Passenger Company to the syndicate known as the New Jersey Traction Company is one of the largest transactions in traction interests ever known. The lease is to run for 999 years, and under its terms the New Jersey Traction Company will enjoy a practical monopoly of the street car traffic in Hudson, Essex and Union counties of New Jersey, and will be in such affiliation with other companies in Mercer and other of the more populous counties as to enable them to control practically the entire traction interests of New Jersey.

U. S. Government Contract

For the Wilmot & Hobbs Manufacturing Company.

The Wilmot & Hobbs Manufacturing Company, of Bridgeport, Conn., have secured recently another large contract from the U. S. Government for their cold rolled "Swedoh" steel, which is being used for some very severe stamped and drawn work that the Government have been making for some time. This steel is something quite new for such work and after being submitted to some very severe competitive tests it has been demonstrated that it is far superior to anything heretofore used for this work. We understand this company is making quite a specialty of it.

Abreast of the Times.

The General Incandescent Arc Light Company, with keen appreciation of the growing demand for efficient arc lamps for use on alternating current systems, has brought out a new line of alternate current lamps which will be supplied in various styles.

Hercules Switches at the Fair.

Office of
D. H. Burnham, Director of Works,
World's Columbian Exposition,
Jackson Park,
Chicago, Ill., March 11, 1893.

Mr. F. H. Angell, Gen'l Agt. Utica Elec. Mfg and Supply
Co., 10 Cornelia St., Utica, N. Y.

Dear Sir: We are in receipt of sample Hercules No. 1 Arc Light Cut-Out and beg to inform you that we have given the same a thorough test, which has proved very satisfactory. This switch was tested by first cutting in 40 lamps, then 50, and finally cutting in 70 lights. The switch operated very satisfactorily up to 50 lights, without any trouble whatever. Up to 70 lights, however, we found it necessary to throw the handle over as rapidly as possible. With this little extra exertion, the switch operated very successfully, and I can congratulate you upon its operation. We yesterday sent you a telegram as follows: "Sample satisfactory; ship Hercules Cut-Outs ordered, with glass covers, immediately."

Yours, very tuly,
S. G. Neiler,
Assistant Electrical Engineer.

Cutter's Economic Door Switch.

The number of incandescent lamps in any place depend not so much on the cost of the current as on the devices for readily turning the lights off and on so as to keep the consumption at a minimum. And even where the switches are conveniently located it requires some attention to turn them, and if this is left to the hired help the chances are that the lamps may be left burning continuously. This is practically the case with closets, store-rooms and such places where the light is needed but rarely. Such parts of the house have generally been left without any convenient means of lighting, merely for the lack of a simple device for controlling the current.

This want is now met by the "Economic Door Switch" devised by George Cutter, of Chicago, which can be set flush in the rabbitt of the door jamb so that the door itself presses against the projecting button. On opening the door the light is turned on and burns until the door is closed when the switch shuts off the current. The action is automatic so there is no possibility of wasting any current when the door is closed, and no hunting for the switch in the dark. The added convenience is worth considerable, while the saving in current and in the life of the lamps will soon pay for the switch itself. Such a device will make the lighting of odd rooms and corners inexpensive, and thus give electricity its well deserved place throughou the house.

The switch as such is well built and has the conducting parts insulated from the casing by hard rubber bushings. The casing is cylindrical, so that it will slip right into a hole drilled in the woodwork, making the fittings a very simple matter. It is being put on the market by George Cutter and will no doubt meet quite a demand.

The C. & H. Double Pole Switch.

In addition to the line of switches recently illustrated in these columns, the firm of Cutler & Hammer, of Chicago, have just placed on the market the new double pole snap knife switch herewith illustrated. The blades and all other parts are made of sheet or rolled copper highly polished and are mounted on slate blocks. The claim made for the switch is that although it is a double break snap switch it costs no more than the ordinary knife switch.

In addition to the above line of specialties the firm have added a very simple and effective automatic motor starter with a magnetic release. In placing the device upon the market the firm believes that it is only necessary to present its merits of safety in connection with motors to the owners of motors and central station men to make them realize that they cannot do without them. A large number of the starters have already been placed in Chicago, due largely to the fact that the underwriters have not only realized the safety the device affords but have insisted that all motors must be provided with an automatic release switch or starter.

Economic Door Switch. *A New Lamp Device.*

A New Lamp Device.

A new device for holding incandescent lamps in any position has recently been placed on the market by Bruce & Nutting, of Chicago. The apparatus is constructed so that a lamp held on the end of the rod can be adjusted to any position either sidewise or up and down within a radius of eight to ten feet. The lamp holder is especially useful in factories, stores shops and draughting rooms or wherever it is desirable to change the position of the light from one place to another and bring it close to the work.

COMMERCIAL PARAGRAPHS.

Mr. A. L. Bogart sends out a circular to the trade, announcing material reductions in prices of his many electric gas lighting specialties.

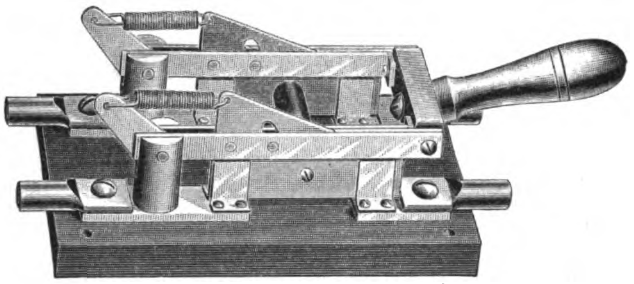
Queen & Company, Incorporated, Philadelphia, are congratulating themselves upon the large number of "Magnetic Vane" Ammeters and Voltmeters which they have sold up to date this year.

An increase of two hundred per cent. over the first seven months of 1892 is not a bad record, especially in the face of recent and present financial disturbances.

The unique porcelain device we illustrated in our columns a few weeks ago, which has been put on the market by the Hammond Cleat Company of Boston, has proved to be a "ten strike." Orders are being received from all parts of the country, and it is being proved that the more they are used the better they are liked.

The new 60 arc light dynamo equipped with the Elkins Automatic Regulator and built by the Consolidated Electric Manufacturing Company of Boston, which has been installed in the electric light station, Old Orchard, Me., is giving perfect satisfaction. It is being run at its full capacity and regulates to the greatest degree of nicety. Changes made from full load to zero do not cause the slightest sparking. It is a remarkably efficient machine and works most economically. The lamps, which were also made by the same company, are very constant and make a perfect arc.

Mr. J. Bradford Sargent, General Eastern Agent for the Sterling Water Tube Boiler, is feeling more than pleased with the extraordinarily fine record recently made after many trying tests of the merits of this now well known type of boilers on the San Francisco and San Mateo Railway. The evaporation of 12.16 pounds of water to one pound of coal is such a result as any firm of boiler makers may well feel proud of, and it is not to be wondered at that so many of these boilers are already in use and others being installed right along. Mr. Sargent has just closed a contract for a 250 H. P. boiler for the Portland (Me.) Street Railway Company.



THE C. & H. DOUBLE POLE SWITCH.

INCORPORATIONS.

Powell Oil Mill Company, Bastrop, Tex.—to manufacture cotton seed oil, gin cotton and supply electric light to the public. Capital stock, $50,000. Promoters: W. C. Powell, P. O. Elzner, J. L. Wilbarger, all of Bastrop.

The Miller Electric Company, 13 Astor Place, New York City—to manufacture and sell electrical appliances. Capital stock, $5,000. Promoters: Sylvanus E. Miller, Brooklyn, N. Y.; Samuel Shethar, New Castle, N.Y.; Edward A. Nichols, New York City.

Santa Cruz Electric Navigation Company, Santa Cruz, Cal.—to construct, own, operate boats, vessels, to be propelled by electricity, sails, steam or otherwise. Capital stock. $10,000. Promoters: F. W. Swanton, Jas. McNeil, Jno. Sullivan, F. W. Ely, Santa Cruz, Cal.

Duplex Trolley Company, New York City—to acquire patent rights for appliances for the transmission of electricity. Capital stock, $10,000. Promoters: C. E. Chinnock, 157 Sixth ave., Jos. Bruns, 346 First st., both of Brooklyn, N. Y.; D. E. Rose, 286 Elizabeth st., New York City.

Atchison Railway and Electric Light Company, Atchison, Kan.—to build, construct and operate street railways in Atchison by electricity or other motive power, manufacture gas and electric light, construct and maintain union stock yards. Capital stock, $250,000. Promoters: Edward Morton, New York City; A. J. Harwi, J. C. Fox, B. P. Waggener, David Kelso, W. P. Waggener, A. W. Simpson, all of Atchison, Kan.

Tucson Water, Electric Light and Power Company, Tucson, Arizona, and Atchison, Kan.—to supply water, electric light and power. Capital stock, $50,000. Promoters: Sylvester Watts, St. Louis, Mo.; Henry A. Lawton, Terry Parker, Stanton Park, James W. Parker, all of Atchison.

The Southern California Development Company, Redlands, Cal.—to deal in, improve and cultivate lands, build and operate water works, machinery, electric plants, etc. Capital stock, $15,000,000. Promoters: A. P. Willoughby, New York City; B. O. Johnson, R. E. Archer, C. E. Fish, Redlands; B. W. Brown, Moreno, Cal.

The Holt Electric Indicator Company, New London, Conn.—to manufacture indicators, ships' logs, electrical apparatus and instruments of precision. Capital stock, $15,000. Incorporators: Geo. B. Prest, Chas. T. Holt, Wm. S. Starr, of New London, and others.

The Pacific Underground Electric Railway Company, San Francisco, Cal.—to deal in patents for underground conduits for electric railways, and manufacture and sell such devices. Capital stock, $100,000. Promoters: J. J. Scrivener, F. S. Chadbourne, Jno. F. Burgin, A. Craig, D. B. Richards, San Francisco.

The Osterholm Electric Belt and Appliance Company, New Haven, Conn.—to manufacture and sell electric belts and appliances and to buy and sell other electrical appliances on commission and otherwise. Capital stock, $1,000. Promoters: John Kallgren, T. O. Osterholm, John Anderson, G. W. Erickson, New Haven.

The Western Printing Telegraph Company, Chicago—to manufacture instruments and appliances and construct telegraph and telephone lines. Capital stock, $1,000,000. Incorporators: Frank R. Walton, James W. Chisholm and Cleaveland F. Dundersdale.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 11, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

501,183. Electric Signaling Circuit. W. Daves, Jersey City, N. J. Filed May 2, 1892.
501,195. Electric Locomotive. Elmer A. Sperry, Chicago, Ill. Filed April 29, 1892.
501,246. Electric Locomotive. Wm. E. C. Eustis, Milton, Mass. Filed Nov. 5, 1891.
501,258. Electric Circuit Closing Device. Wm. Seals, Boston, Mass. Filed April 10, 1893.
501,307. Railway Signal. James Wayland, Newark, N. J. Filed Jan. 21, 1892.
501,438. Railroad Crossing Alarm or Signal. Elwood C. Potter, Vineland, N J. Filed April 6, 1891.
501,481. Trolley Wire Hanger. Alexander W. Meston, St. Louis, Mo. Filed Oct. 31, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

501,074. Electric Arc Lamp. J. Jergle, Austria-Hungary. Filed Nov. 25, 1891.
501,080. Electric Arc Lamp. G. Kirkegaard, Brooklyn, N.Y. Filed Nov. 12, 1892.
501,081. Electric Arc Lamp. G. Kirkegaard, Brooklyn, N.Y. Filed Feb. 20, 1893.
501,095. Electric Lighting System. P. Nordmann, Berlin, Germany. Filed Nov. 18, 1892.
501,170. Duplex Electric Arc Lamp. Chas. E. Scribner, Chicago, Ill. Filed Oct. 27, 1890.
501,183. Electric Signaling Circuit. Wm. Daves, Jersey City, N. J. Filed May 2, 1892.
501,205. Socket for Incandescent Lamps. Ekel Ekstrom, Lynn, Mass. Filed June 27, 1892.
501,206. Electric Current Apparatus. Jonathan P. B. Fiske, Lynn, Mass. Filed Aug. 12, 1891.

DYNAMOS, MOTORS, ETC.

501,049. Commutator Connection. Norman C. Bassett, Lynn, Mass. Filed Feb. 9, 1893.
501,059. Regulator for Dynamo-Electric Machines. William H. Elkins, Cambridge, Mass. Filed June 23, 1892.
501,060. Brush for Dynamo-Electric Machines and Motors. Jonathan P. B. Fiske, Lynn, Mass. Filed Jan. 31, 1893.
501,117. Dynamo-Electric Machine. Harry L. Tyler, Corning, N. Y. Filed Oct. 17, 1892.
501,193. Commutator Brush Holder. Alton J. Shaw, Muskegon Mich Filed Feb. 17, 1893.
501,194. Revolving Armature for Electric Machine. Elmer A. Sperry, Chicago, Ill. Filed Jan. 8, 1892.
501,309. Method of Regulating Dynamo Electric Machines. Merle J. Wightman and Hermann Lemp, Hartford, Conn. Filed Feb. 13, 1886.
501,376. Armature. Joseph J. Smith and Geo. W. Findlater, Jamaica, N. Y. Filed May 26, 1892.
501,482. Revolving Motor. Herbert L. Parker and Alexander W. Meston, St. Louis, Mo. Filed Oct. 22, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

501,085. Telephone Circuit and Apparatus. S. J. Larned, Evanston, Ill., and F. A. Pickernell, Newark, N. J. Filed March 20, 1893.
501,086. Station Apparatus for Telephone Circuits. S. J. Larned, Evanston, Ill., and F. A. Pickernell, Newark, N. J. Filed March 20, 1893.
501,087. Electric Signaling. T. D. Lockward, Melrose, Mass., and Sherwood J. Larned, Evanston, Ill. Filed March 27, 1893
501,102. Telephone Signaling Apparatus and Circuit. F. A. Pickernell, Newark, N. J. Filed March 20, 1893.
501,168. Telephone Switch. Chas. E. Scribner, Chicago, Ill. Filed Dec. 27, 1886.
501,169. Telephone Exchange Apparatus. Chas. E. Scribner, Chicago, Ill. Filed June 6, 1888.
501,185. Visible Signal. Francis W. Dunbar, N. Y. Filed May 4, 1893.
501,405. Support for Telephonic Receivers. Norval L. Burchell and Burnet L. Nevius, Jr., Washington, D. C. Filed Nov. 3, 1892.
501,472. Station Apparatus for Telephonic and Telegraphic Circuit. Theodore Spencer, Cambridge, Mass. Filed Feb. 20, 1893.

BATTERIES.

501,151. Electric Battery. James H. Mason, Brooklyn, N. Y. Filed Nov. 14, 1892.

MEASURING INSTRUMENTS.

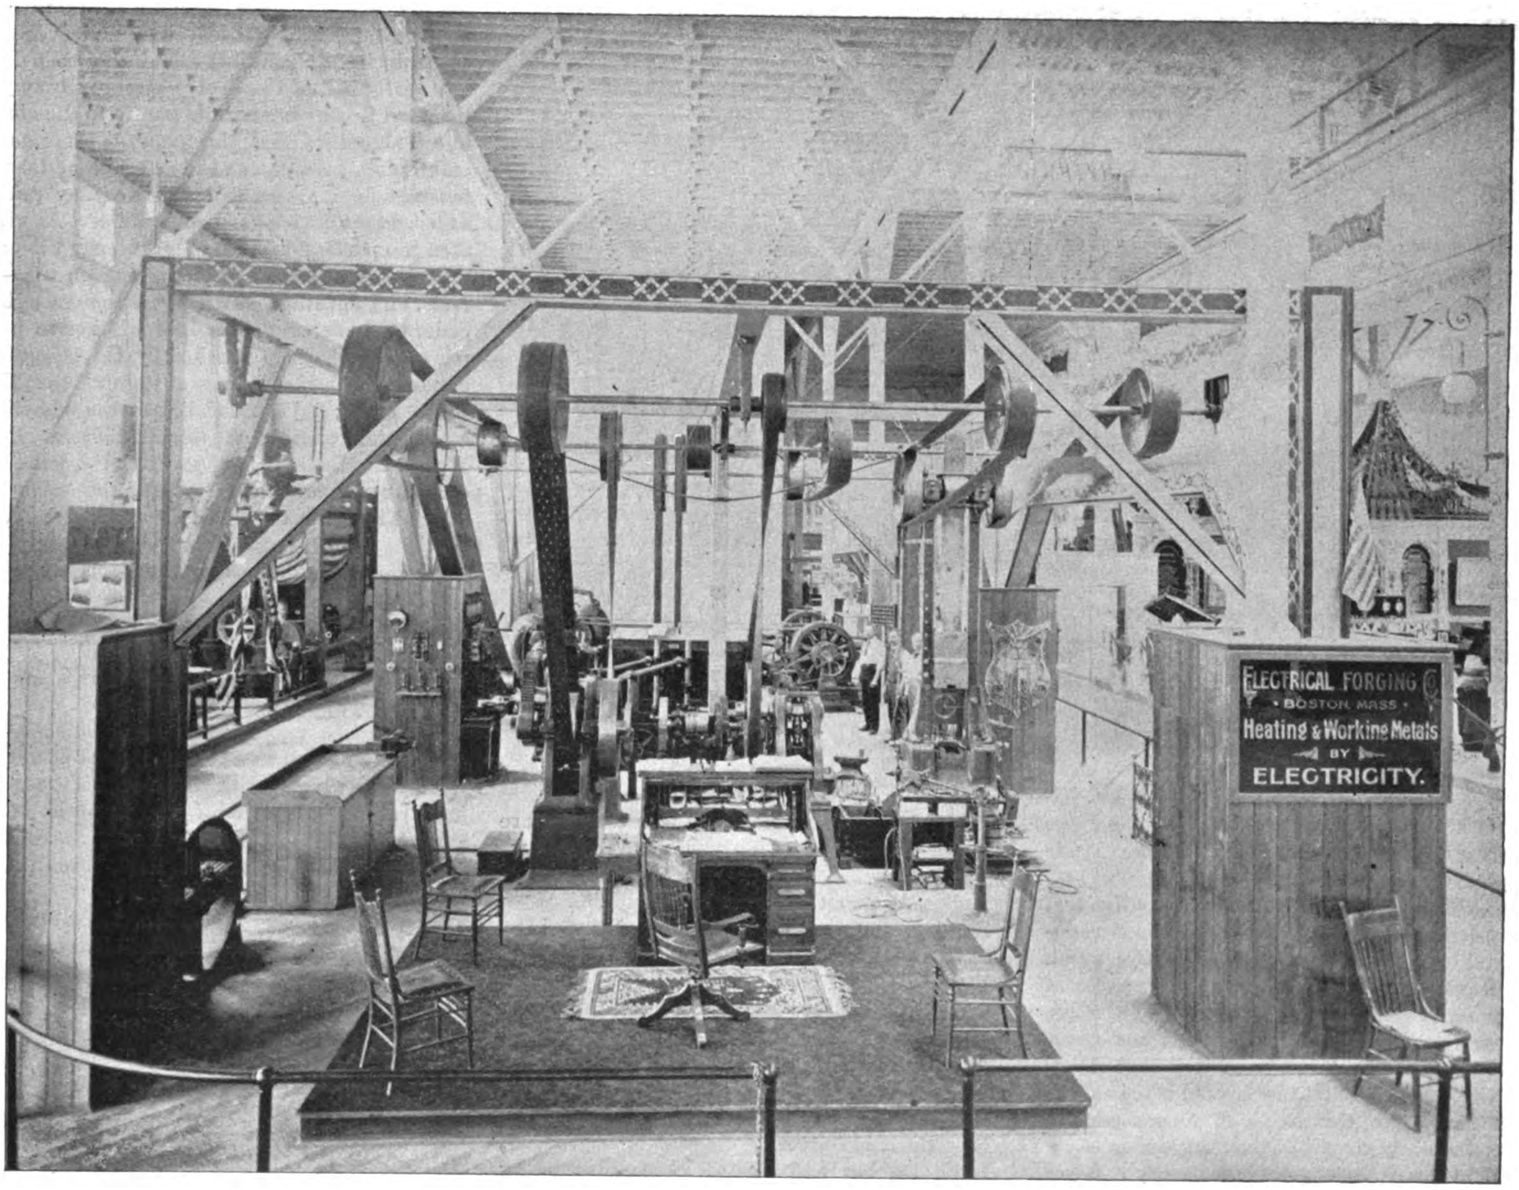
501,104. Ammeter. Wm. Hockhausen, Brooklyn, N. Y. Filed Feb. 28, 1891.

MISCELLANEOUS.

501,068. Electric Snap Switch. Caryl D. Haskins, Lynn, Mass. Filed Jan. 24, 1893.
501,071. Electric Switch. Carl Friedrich Wilhelm Hofer, Berlin, Germany. Filed March 25, 1893.
501,094. Equalizer for Rotary Current System. P. Nordmann, Berlin, Germany. Filed Feb. 23, 1893.
501,114. Lightning Arrester. E. Thomson, Lynn, Mass. Filed June 20, 1890.
501,178. Electric Switch. Frederick A. Thum, Newark, N. J. Filed March 14, 1893.
501,191. Switch for Electric Conductors. Olaf Offrell, Middletown, Conn. Filed Aug. 12, 1892.
501,201. Automatic Circuit Interrupter. Alexander Wurts, Pittsburg, Pa. Filed Oct. 5, 1892.
501,241. Lightning Arrester. James E. Browne, Elizabeth, N. J. Filed Sept. 12, 1892.
501,270, Letter Box. Peter J. Fitzgerald, Hyde Park, Mass. Filed Oct. 13, 1890.
501 291. Electric Time Switch. James F. McLaughlin, Philadelphia, Pa. Filed Sept. 29, 1892.
501,292. Electric Bell. Wilson J. Newman, Brooklyn, N.Y. Filed Oct. 28, 1892.
501,306. Electric Alarm Money Drawer. William J. Walker and Alexander L. Bedford, St. Louis, Mo. Filed April 12, 1893.
501,445. Junction Box. William Brooks Sayers, Glasgow, Scotland. Filed June 16, 1892.
501,450. Electric Switch. Lucius T. Stanley, Brooklyn, N. Y. Filed March 27, 1893.

ELECTRICITY.

VOL. V. NEW YORK. AUGUST 16, 1893. CHICAGO. No. 5



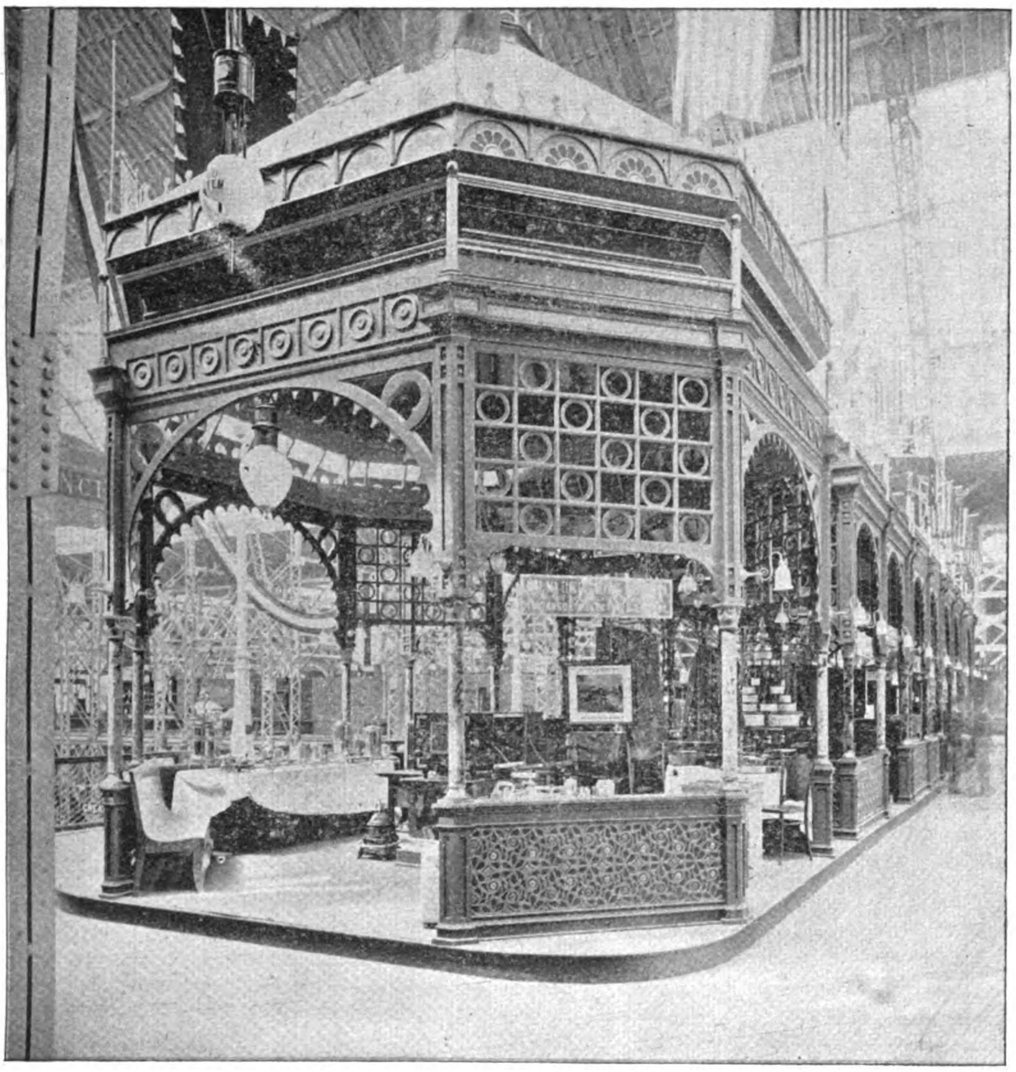
ELECTRICAL FORGING COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 50)

World's Fair Notes.

Electrical Forging Company's Exhibit.

The exhibit of the Electrical Forging Company of Boston, which is located on the east side of the main floor of the Electricity Building, is one of the most novel and at the same time interesting displays that can be found among the many machines in the building. Except for this exhibit it might well be said that the northeast corner of the Electricity Building would have little attraction for the ordinary World's Fair visitor.

Most of the patrons of the Exposition want to see a machine "where the wheels go round." The Electrical Forging Company seem to have appreciated this fact and have arranged to have their machines in continuous operation during the greater part of the day and evening. That the work is appreciated is proved by the large crowds always to be seen around the space occupied by the company.



Ansonia Electric Company's World's Fair Exhibit.

The exhibit, which is shown in our Frontispiece, consists of nearly all the different machines manufactured by the company. The generator which supplies the current for the heater is capable of delivering 35 amperes at a pressure of 2,400 volts. The current is delivered to a 5-foot transformer the core of which contains over 800 pounds of soft iron wire. The metal to be heated is placed between the jaws or clamps which form a portion of the secondary circuit of the transformer.

Arrangements are made so that eight pieces of work can be heated in as many different clamps at one time. The gentlemen in charge illustrate the operation of the machine by actually heating rods of various metals of from one-eighth to three inches in diameter. They also show the method of welding iron, steel and brass bars.

One of the most interesting and puzzling parts of the exhibit, both to the layman and the electrician, is the raising of the temperature of a bar of iron to a welding heat by placing it in a pail of water. The many amusing questions asked of the attendants in regard to this feat would stock a specialty actor for a year to come should he jot them down. The exhibit is in charge of Mr. George H. Burton, the inventor, assisted by Mr. Williams.

Ansonia Electric Company's Exhibit.

The exhibit of the Ansonia Electric Company, as illustrated in this issue, consists of a combined display of electrical supplies manufactured by the numerous companies of which the Ansonia Company are the Western representatives. The pavilion, which occupies the centre of the north gallery, is arranged so that each of the manufacturing concerns has a separate section for its goods. Among the companies whose names are hanging over the many entrances are the following:

Helios Electric Company, Philadelphia.
Stanley Manufacturing Company, Pittsfield.
J. Lang & Company, Chicago.
Richard Pfund, New York.
Cutter Electrical Manufacturing Company, Philadelphia.
American Electrical Heating Corporation.
Star Electric Company, Chicago.
Wm. Burnley, North East, Pa.
Electric Manufacturing Company, Dayton, O.
India Rubber and Gutta Percha Insulating Company, N. Y.
Otto Rauda, New York.
National Electric Manufacturing Company, Milford, Conn.

Besides the above, a large number of other companies have representation in the shape of small exhibits. Nowhere can a person gain a better idea of the extensive line of supplies carried by the Ansonia Company than by a visit to their exhibit. In their pavilion the company claim to not only show some of the latest electrical appliances of the day but also some of the earliest. Included among the latter are some of the machines used by Moses G. Farmer and William Wallace in their early experiments in electricity. The photograph illustrating the pavilion is taken from the end occupied by the American Electric Heating Company, and it may be said that it forms a very interesting part of the exhibit. Lectures in cooking by electricity are given three times a week, and practical demonstrations are made on numerous electrical utensils. The Ansonia Company have installed an electrically operated elevator near their booth, and are carrying free all visitors who wish to go to the gallery floor.

Performance of Street Railway Power Plants.

BY WM. A. PIKE AND T. W. HUGO.*

No mechanic art has become so interwoven with our everyday existence as that of electric engineering. No branch of industry has grown, in so short a period of time, to the proportions now assumed by the practical applications of the developments of the science of electricity, and as a consequence the application has been in advance of the definite knowledge of the results of such application; in other words, the application has led the pace, and that being a fast one the engineer is now almost breathless, endeavoring to catch up and find out just what he has been doing. Especially is this the fact in street railway practice, and it is to contribute a mite to the general knowledge box that this paper is presented, as embracing, possibly, as wide a scope and as extensive a field, under ordinary everyday practice as has heretofore been made public. As will be seen, no particular piece of machinery was under criticism, no person's creation was on trial—the facts, and nothing but the facts, being sought, in order (1) to ascertain the cost of motive power per car mile [*a*] as furnished by the tri-cylinder condensing Corliss engines at Power House No. 1, Minneapolis; [*b*] as furnished by the tri-cylinder condensing engines at the Hill Street Power House, St. Paul; [*c*] as furnished by the two-cylinder non-condensing Westinghouse engines at the Thirty-first Street Power House, Minneapolis.

(2) To obtain data as to the economy of the boilers used.

(3) To obtain data as to the relative value of crude petroleum and coal as fuel.

(4) To compare the cost of furnishing power by large tri-cylinder condensing engines and small Westinghouse two-cylinder non-condensing engines, or concentrated vs. subdivided power.

The tests which are the basis of this paper were made at the instance of Mr. Thomas Lowry, President of the Twin City Rapid Transit Company, Minneapolis and St. Paul, Minn., on the various plants of the company.

The tests at Power House No. 1, Minneapolis, and the principal tests at the Hill Street Station, St. Paul, were made under the joint supervision of Messrs. Wm. A. Pike, of Minneapolis; T. W. Hugo, of Duluth, members of the American Society of Mechanical Engineers, and Mr. Aid Collins, agent of the Hartford Boiler Insurance Company, of Minneapolis, the test using screenings for fuel at St. Paul; and the tests at the Thirty-first Street Power House, Minneapolis, were under the direction of Mr. Pike alone. It is perhaps proper to state that the first proposition for these tests was made to the Hartford Boiler Insurance Company, but as this company did not care to undertake the work it was arranged for as stated above. Acknowledgment is hereby made of the courtesy of Mr. Thomas Lowry in allowing the publication of these results and of the very efficient services of a large number of engineering students from the University of Minnesota, who constituted the greater part of the corps of observers.

---

* Abstract of paper read at the Chicago Meeting of the American Society of Mechanical Engineers.

It might be interesting to describe many of the details, such as the commissary department, necessary to provide for supplying the needs of the thirty persons engaged in this particular work. None of the regular employees took any part in anything connected with the extra work of the tests; they merely kept the plant in its usual working conditions. Many features required considerable thought which in tests on a small scale demand very little consideration, but it is believed that the technical features alone will comprise a bulky paper, and some of the incidents may form the subject matter for future papers. Although much care and attention were given to every detail, yet the pump which causes trouble when most urgently needed, the joint and the valve which leak on such occasions but at no other time, the indicator spring which breaks, the cord which stretches, the fellow who lets the indicator cards fall into the oil tank, and the kodak fiend were all on duty, and the usual makeshifts and improvisations were called into service, and the genius of the operators taxed to keep things moving, and it is believed that the results obtained are correct and worthy of study.

TEST NO. 1, MINNEAPOLIS, MARCH 5, 1893.

Power House No. 1 contains the plant from which was obtained the power used during the first series of tests, two tri-cylinder condensing engines of the design of the E. P. Allis Company, of Milwaukee, Wis., together with a single cylinder engine of the same make, five Babcock & Wilcox and two Stirling water tube boilers, sixteen Edison railway generators of 175 kilowatts capacity, and two of 89 kilowatts, constitute the motive machinery. Each of the two tri-cylinder engines was belted to a line shaft through which the power was transmitted to the generators, and also to a 100-light Excelsior, new style, arc dynamo, furnishing lights as needed.

The system of transmission is the single trolley overhead system, operating eighteen car lines with a total of about eighty miles of track, including that portion of the inter-urban line connecting Minneapolis and St. Paul from Minneapolis to Midway, a distance of about four miles. Motors ranging from 15 to 30 H. P. of the Sprague and the Thomson-Houston types are used on the cars.

PRECAUTIONS TO INSURE ACCURACY.

(1) Previous to the tests all steam gauges used were tested by comparison with a mercury column, and then either corrected, or a table of errors made from which true pressures were obtained.

(2) All indicator springs were tested under steam pressures by comparison with a correct gauge, and either found correct or their numbers changed to correspond with true pressures.

(3) All thermometers were tested by comparison with boiling and freezing points, and by comparison with a standard thermometer.

(4) All scales used were adjusted and certified to by Fairbanks, Morse & Company.

(5) The pyrometers were compared with a correct thermometer in a smoke flue, and a table of corrections made.

(6) The water meter used for measuring the injection water was calibrated by weighing the water actually discharged and comparing it with its readings.

METHODS ADOPTED IN CONDUCTING THE TESTS.

During the whole time occupied in the tests all observations necessary to obtain the desired data were taken every stated ten minutes, an electric gong operated by the timekeeper giving the signal to all, except in the case of the ammeter readings, which were taken every fifteen seconds; the current was all passed through two ammeters so regulated that an equal amount of current went through each. The voltage was practically constant, and was also noted.

All water and fuel oil were weighed accurately before passing to the boilers. Two large wooden tanks were elevated on scales placed on platforms. The supply for those tanks was provided with a branch pipe and stop-valve for each tank, and by a stop-valve and pipe from the bottom, each discharged into the iron receiving tank.

The feed water was pumped to the weighing tanks by a 7 x 10 x 10 inch duplex steam-pump, and taken from the iron receiving tank by a second steam-pump of the same size and sent to the boilers.

The fuel oil was pumped by a 4½ x 2¾ x 4 inch duplex pump into two iron tanks placed on scales elevated on a platform from which, by discharge pipes at the bottom and stop-valves, the oil was drawn off into another iron tank, also elevated on a platform, from whence by gravity it was conducted to the atomizers that supplied the furnaces.

During ordinary running but one of each of the above-mentioned pumps is used, the other being held in reserve.

During the first test the Babcock & Wilcox boilers, Nos. 1, 2, 3, 4, 5, supplied steam for the two tri-cylinder engines exclusively, except that used for atomizing the fuel oil fed to the furnaces of those boilers, for which, however, a proper deduction is made.

To supply the steam for the condenser engines, feed and oil pumps, and for the heating system of the building the Stirling boiler No. 2 was used, and a separate pump, 4½ x 2¾ x 4 inches, supplied it with feed water.

All possible outlets for either steam or water, except those necessary for furnishing steam to the engines and water to the boilers, were blanked off or known to be tight, except in one case hereafter noted.

Steam-engine indicators were attached to each end of each cylinder, the motion being received through a swinging pendulum, the cords being guided by a properly constructed arc fastened to this pendulum; and as in these tests twelve indicators were in some cases employed, and as it was considered advisable to have the diagrams taken simultaneously, an electric attachment was devised, by means of which the pencils of all the instruments were moved up to their respective drums at the same instant.

In addition, an indicator was attached to each of the condenser engines and diagrams taken at the usual stated periods, at the sound of the signal gong.

The water collected from steam-jackets and separators was weighed separately, as is more fully described hereafter.

The revolutions of the engine were obtained from continuously recording revolution counters, and, in connection with boiler and receiver pressures, and vacuum gauge and barometric readings were noted at each stated period of ten minutes.

At the stated periods the height of water and oil in the feeding tanks, and the height of water in the boilers, as shown by the glass water-gauge, was noted, so that if, by any accident, it became necessary to stop the test before the expiration of the expected time the data of the entire test would not be lost, and by going back to the last stated period a general summing up could be made covering the actual time of the test; also, these figures for each stated period are valuable as checks on final results.

Calorimeters of the barrel, separator, and throttling type for determining the percentage of moisture in the steam were attached to the main steam-pipe in the boiler room to feed the pipe of each engine just above the throttle valve.

The pyrometers and draught gauge were inserted in the main flue, and a record kept, as well as of the steam-pressures and feed-water temperatures at the boiler.

Samples of the fuel oil used were taken for chemical analysis at suitable intervals.

On blanks furnished each street-car conductor was noted every stated ten minutes:

(1) Whether moving or stopped.

(2) Number of passengers.

(3) Location of car.

(4) Whether car is lighted or not.

A record was kept of the number of lamps burning, and the length of time in use at the different stations and other places, from which the power used for this purpose was calculated.

Kind	Babcock & Wilcox
No. of head drums	2
Diam. of head drums	36 inches
Length of head drums	17 feet 8 inches
Diam. of water tubes	4 inches
No. of tubes { 144 main tubes	17 feet 9⅛ inches
16 tubes between headers and drum	7 feet 4 inches
16 headers	5 feet high x 6 inches wide
Mud drum	9 feet long, 18 inches diam.
Area of grate	71 square feet
Heating surface (figures from makers)	3,128 square feet
Ratio of grate to heating surface	1:44
Distance from grate to tubes	3 feet 8 inches at front, 2 feet 4 inches at bridge

Each Babcock & Wilcox boiler has two steam-pipes, stated to be 5⅝ inches in diameter, and is 2 feet 4 inches long, connecting with an 8-inch pipe having two L's and one , which connects with a 12-inch header. This header, after leaving boiler No. 5, connects with a 15⅝-inch main, running to separator No. 1. This main is 175 feet 2½ inches long, and after making five turns connects with the separator at a point 2 feet 6 inches from the bottom, and one 10-inch branch is taken from the top of the separator and runs to engine No. 1, and from the opposite side of the separator, and 15 inches above the inlet, a 15⅝-inch pipe runs to separator No. 2, 45 feet 9 inches distant.

The water collected in the separators and jackets is usually drawn therefrom by ordinary steam-traps and discharged into a tank from whence it is pumped to a receiver in the boiler room, where, after being mixed with sufficient overflow water from the condensers, it is used for feed water.

The pipe supplying jackets is 1¼ inches in diameter and is connected to a T in the branch steam-pipe 4 feet above the separator of the main steam-pipe.

The steam-pipe from each separator to the engine is about 10 feet long and 10 inches diameter, with one turn, to a valve, then with four turns to the engine it is 8 inches diameter and 56½ feet long.

The Stirling boilers have each one 8-inch steam-pipe 27 feet long, with two turns and an angle valve, connecting to a header 8 inches diameter from the Stirling boiler No. 1 to No. 2, and 12 feet long, connected by an 8 x 12 x 8 inch T to a 12-inch header, 28 feet long, having two turns, to the main steam-pipe before spoken of in connection with the Babcock & Wilcox boilers.

During the main test the Stirling boiler No. 2 was piped directly to condenser engines, to feed water and fuel-oil pumps, and to heating system for building, as follows: A 3-inch pipe, 96 feet long, with five turns to the feed pumps, pipe bare; a 3½-inch pipe, 208 feet long, with five turns, runs to the condenser engines—108 feet of this pipe in the basement was covered; a 3-inch steam-pipe to the heating system of the building.

All other steam-pipes are protected by, first, a dead air-space of ⅝ inch, made by a sheet-iron cylinder with collars turned in at the ends, and then covered with asbestos cement ⅞ inch thick.

The tri-cylinder engines are of the cross compound type with the high pressure, and intermediate cylinders arranged tandem on one side, and the low pressure by itself on the opposite side, with its crank 90 degs. from the other, and reheater receivers between the cylinders.

The exhaust from the H. P. cylinder is carried to No. 1 receiver, which is 27½ inches diameter and 15 feet 6 inches long, and from which the supply to the intermediate cylinder is taken.

The exhaust from the intermediate cylinder is carried to No. 2 receiver, which is 28½ inches in diameter and 21 feet 6 inches long.

These receivers are surrounded by a jacket space of 1⅝ inches, the whole protected by a covering of asbestos, except the ends, which are uncovered.

The cylinders of both engines have a steam-jacket space of about 1½ inches, and are then covered with a layer of asbestos cement 2½ inches thick, covered over all with sheet-steel. The heads are jacketed, but not covered with asbestos. All ends except the crank-ends of the intermediate and low-pressure cylinders have false covers.

The steam for these jackets is taken from the main steam-pipe after leaving the separator No. 1; on the one side it passes around the H. P. cylinder, then around the intermediate cylinder, then around receiver No. 1. On the other side it passes first around the low-pressure cylinder, and then around the receiver No. 2, between the intermediate and low-pressure cylinders.

(To be continued.)

Alternate Current Motors for Railway Traction.

The Pittsburg *Despatch* has the following:

"Mr. Westinghouse has recently secured patents for a system of operating cars by means of currents in bars conveyed underground in proper conduits. Instead of using the continuous current for the supply of electricity, the alternating current will be used, so that no current will have to be returned through the rails and water pipes. A pair of high tension lines will be laid along the line, and the current will be reduced to a safe working pressure by converters and fed into short sections of the railway conduit, so that, in the first place, there will be no traveling of the current over long distances, and, secondly, the current being of the alternating character, will not produce the electrolytic action which seems to be the occasion of destruction to iron and lead pipes.

"When asked if he intended to introduce this new underground system, he said that he had already opened negotiations with reference to its use in a large Eastern city, and that the company is now ready to take up this branch of the electric street railway business on a large scale. It is expected that as soon as the first experimental lines are laid and successfully worked, it will lead to the general introduction of the underground system in New York and other large cities.

"There are several hundred miles of railway in New York now operated by horse power which should be operated by electricity, and which the authorities there will not permit to be operated by the trolley system if a suitable and economical arrangement of underground wires can be shown to be practicable.

"W. L. Elkins, Jr., President of the Pennsylvania Iron Works Company, of Philadelphia, which is largely engaged in constructing machinery for cable roads, is now in the city going carefully into the details of the new plans."

Personal.

Announcement is made of the marriage of Mr. M. J. Sullivan to Miss Frances Read, on August 15, at the home of the bride's parents at Freeport, Ill. Mr. Sullivan has recently assumed the management of the Western office of the *Electrical World* and is well known among the electrical fraternity. The bride is an estimable young lady, and has recently acquired the acquaintance and friendship of a large number of the exhibitors in the Electricity Building, having had charge of the *Electrical World's* booth in that building.

Electric Belts.

The Electrical Exhibit at the Fair Disgraced by Their Admission.

How the Ignorant are Humbugged.

Some time ago the *Evening Post* of this city called attention to the lack of popular information in regard to the subject of electro-medical appliances, stating that even men of intelligence and education were not able to determine which of the many appliances advertised were recognized by electricians as legitimate and which were frauds. While recognizing the services performed by Electricity in exposing the humbugs, the *Post* thought that electrical journals generally should give more attention to the matter, and make it plain to the uninformed just what might reasonably be expected of the electric current as a remedial agent.

If a well-informed metropolitan journal confesses its ignorance of this subject, which is not at all to be wondered at, it is evident that the masses throughout the country can have no conception whatever of the subject of legitimate electro-therapeutics.

The electrical journals can, to a certain extent, aid in promulgating a correct understanding of the subject, but to the regular readers of these journals the matter is fairly understood, and at least the bolder frauds are already known to them.

These fakirs usually advertise their wares in the country districts and in city papers reaching the poor and ignorant, and work on a class of people who can always be relied on to patronize the medical quack, whether he be "electrical" or otherwise.

Up to a few months ago, therefore, there appeared little reason why an electrical journal should devote much space to the subject of "electric belts," etc.

The action of the World's Fair management, however, in admitting a miscellaneous lot of manufacturers of electro-medical apparatus, both good and bad, has rendered some action by the electrical press imperative.

If the matter were allowed to pass by without vigorous protest, infinite injury would result to the science and to all legitimate workers in it.

Every visitor to the Electricity Building is today justified in supposing that the manufacture and sale of electric belts is recognized as an entirely reputable branch of the electrical trade—just as much so as the manufacture and sale of Weston instruments, of standard dynamos, or of any other exhibit in the building.

The frauds have no right to be there, and even at this late day should be ordered peremptorily to withdraw. Giving them all possible credit, they are as much out of place in an exhibit of electrical apparatus as a display of patent medicines would be in the building of Manufactures and Liberal Arts. Hence, Electricity feels justified in making it plain that electricians have no desire to stand sponsor for them, and in showing their true standing. The electric belt is not one of those things regarding which "faith is a boon and unbelief a calamity," but directly the opposite.

We shall look to the daily press to aid us in the dissemination of the truth in this matter.

There is particular propriety in calling attention to the facts now, for reasons which will be apparent as we proceed.

A couple of weeks ago there appeared in a Chicago paper an account of an informal reception tendered by Dr. Alva Owen, he of the whiskers and electric belts, to the exhibitors in the Electricity Building. A few of the exhibitors accepted the invitation, and spent the afternoon at Dr. Owen's famous stock farm, near the city.

It is not known just what methods were adopted by Dr. Owen to convince his guests that electric belts were a boon to the human race, but he seems to have partially accomplished his purpose. Of one thing there was convincing proof—that the sale of these belts has been *profitable;* for no longer ago than 1885 this man Owen, according to his own statement, was "a practising physician" in St. Louis, and "sleeping on a chair in his office," trusting to a "kind Providence" for his daily bread. Providence appears to have been more kind to Dr. Owen than to the deluded purchasers of his belts.

Besides the farm and its splendid equipments, all speaking eloquently of the merits of the electric belt scheme, there may have been other evidences of the efficiency of the belts themselves. Possibly the Doctor pointed with pride to his herds of Holsteins or Jerseys, and showed how by the ingenious application of the belts the dairy industry could be revolutionized, and a perpetual supply of milk obtained without recourse to the usual methods for securing a renewal of the flow every spring.

Possibly, again, he showed how, by placing the belts on the cupolas of his house and barns, lightning rods were safely dispensed with.

Certain it is that within a few days after this reception a petition was circulated among the exhibitors and handed in to Prof. Barrett, praying that the Jury of Awards might sit on these belts. We trust that they will do so, and sit on them hard.

The petition reads as follows. It reveals about as correct an understanding of the English language as do the belts of the laws of electro-therapeutics:

Prof. J. P. Barrett,
Chief Department of Electricity.

Dear Sir: There having been more or less said against the electric belts exhibited in this building, and referring to them as fakes, we the undersigned respectfully request that said belts be submitted to a jury for them to test same for voltage, amperage and internal resistance.

We ask this to sustain you in your action in giving them a space, and also in justice to themselves as exhibitors. There are many electrical appliances and belts that are fakes, from which no current can be obtained, and those that do not have merit should be known, especially the exhibitors that you have admitted in this Electrical Building in the World's Fair.

The Jury of Awards should, and no doubt will, be extremely cautious how they handle this matter.

There are probably no belts exhibited by these charlatans which generate no current.

The phase of the subject on which the public needs enlightenment is, what diseases, if any, may be cured by the indiscriminate application of the electric current in this manner?

For an answer to this question men of common sense will naturally look to reputable physicians of unquestioned standing, who have spent years in conscientious investigation and experiment—men, for example, like Dr. W. J. Morton, of the American Electro-Therapeutical Association. Taking the results of the investigations of men of this calibre as a guide, we assert that these electric belts, electric hair-brushes, electric headache cures, electric light baths, etc., etc., are unqualified frauds upon the public, and that their admission to the Electricity Building was a disgrace and a misfortune. They are frauds, or else the therapeutical and electrical authorities are all wrong.

The glaring advertisements of these so-called physicians are indeed enough to brand them as charlatans, as the ethics of the medical profession exclude anything in the way of advertisements most rigidly, and even the most obscure practitioners are careful to avoid notoriety by this means. No physician of standing will consent to associate or consult with one of these advertising specialists, and this fact shows the standing in which they are held by the reputable members of the medical profession.

Another direction in which these outcast doctors violate the rules of the profession is in taking out patents on medical or surgical apparatus. This is never done by reputable physicians or surgeons, among whom any improvements in apparatus or appliances are considered common property for the benefit of all. To patent and monopolize an article which according to its inventor is almost indispensable to health and comfort is hardly compatible with the humanitarian spirit which pervades the literature of medical advertisements.

The circulars of a number of these fakirs are before us. One makes capital of the fact that he was awarded two gold medals at the Tasmania International Exhibition: "These medals were awarded and presented to Dr. G. F. Webb by direction of Her Majesty the QUEEN OF ENGLAND." Dr. Webb also cites authority to prove that he has been allowed to keep his bank account in the Arcade Savings Bank of Cleveland, "his checks always finding funds to meet them." Fortunate Webb! A man who always has funds to meet his checks must of course make good belts. These circulars all present imposing collections of testimonials from those who think they have been cured by the humbug appliances. That of Dr. Owen, the chief offender, may be taken as a fair sample of all. In it are enumerated the following diseases, to the cure of which his belt "is especially adapted." It is a sickening array of physical disorders, and it will be seen that there are few omissions. No one need die short of old age, if he will only wear an electric belt:

Kidney Complaints,
Urinary Diseases,
Catarrh,
Asthma,
Dumb Ague,
Throat Troubles,
Deafness,
Neuralgia,
Sciatica,
Insomnia,
Hysteria,
Melancholia,
Paralysis,
Epilepsy,
Whites,
Leucorrhœa,
Irregularities,
Suppressed and Painful Menses,
Female Weakness,
Change of Life,
Seminal Weakness,
Dyspepsia,
Torpid Liver,
Constipation,
Piles,
Wasting,
Headache,
General Debility,
Rheumatism,
Lumbago,
Gout,
Pain in Back,
Spinal Disease,
Cold Extremities,
Sluggish Organs,
Nervous Debility,
Local Debility,
Varicocele,
Sexual Exhaustion,
Impotency,
Sterility,
Epileptic Fits.

In addition to Dr. Owen's exhibit at the Fair there are those of Dr. Pratt, Dr. G. F. Webb, and the Pulvermacher Company. The "Actina" people were ordered out some time ago as the result of the exposure made by ELECTRICITY. The claims of these people, it is only fair to state, are supported by a great many people who are supposed to be intelligent, including some engaged in the electrical business, though not scientific men.

Cures may have been effected by the use of these belts, in the same manner that one may be cured of a head ache by stubbing his toe, or of a stomach ache by putting a fly blister on his left shin—that is, by diverting the patient's attention from his chronic aches and pains by giving him other aches and pains to think about.

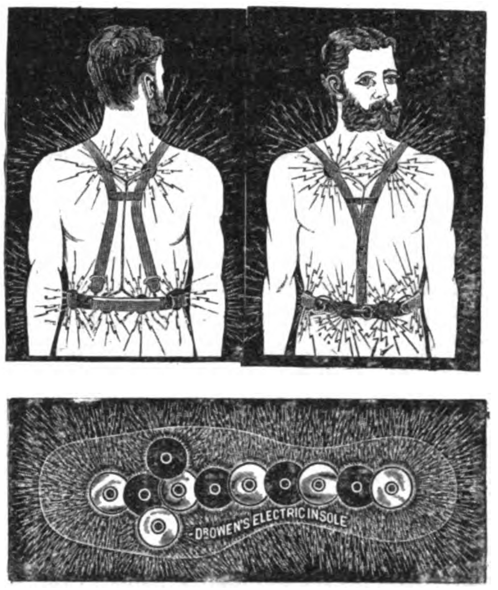
But that one and the same application will cure diabetes and deafness, epilepsy and piles, torpid liver and toothache, swelled head and cold feet, is too much to believe.

Any of the above diseases might be properly treated electrically; in none of them could an electric belt be of any real benefit. In many of them it would be a positive injury, and likely to produce serious effects.

The kind of current to be applied, the method of its application, can only be determined by a careful consideration of each special case by a competent physician.

The man who will recommend one universal treatment, of any nature, for such diseases as kidney complaint, spinal weakness, paralysis, etc., is worse than a quack; he is a criminal, in that his advice if followed may produce irreparable injury, or even the death of the deluded patient.

The following illustrations represent some of the principal electrical outfits which are offered by the medical quacks and which are generally warranted to alleviate or remove all the ills which flesh and blood is heir to. As a further guarantee of good faith and the effectiveness of these goods they are generally accompanied by a portrait of the inventor, whose features are fringed with an artificial lightning, secured by letters patent to do duty as a trade-mark.

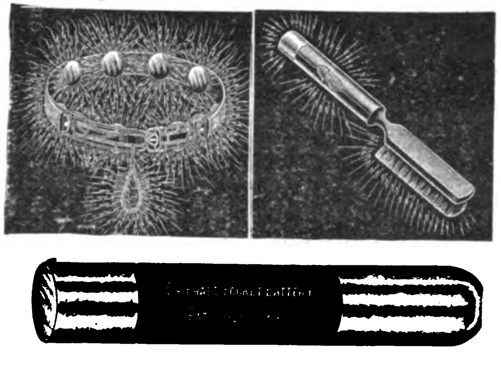


Electric Spinal Appliance, front and rear view, and Electric Insole.

These appliances all produce an electric current, and as electricity cures certain diseases it is argued that the appliances must cure the same.

Pathologists generally accept the fact that up to the present the use of electricity in medicine is largely empirical, and that the three forms of current usually employed, viz., galvanic, faradic and static, may be used to soothe or destroy according to the application, the same as with the use of drugs.

General electrozation must be considered dangerous. Deafness and paralysis have been cured by lightning discharges, but this treatment was unpremeditated, and its action remains a mystery.



Electric Belt, Electric Hairbrush, and Electric Headache Cure.

In therapeutics electricity is of considerable value, but can by no means be considered a panacea. The symptoms produced by a current cannot always be predicted, and it has no analogue in the *materia medica*.

It has produced two distinct sets of symptoms, one during and the other after application, and these are sometimes directly opposite in nature. It seems apparent from this that the application of a current to any part of the body should be made by an experienced physician, and that the promiscuous and undirected use of electricity, without distinction as to the kind of current, is more apt to be wrong than right. An article that will do injury in ten cases while it is beneficial once is not to be recommended to the public for a trial. Whatever possible good may be done by these articles is greatly outweighed by their possibly injurious effects in nine cases out of ten. The fact that no reputable physician recognizes these advertised cure-alls should be a sufficient clue to the character of the imposters who thrive upon the credulity or ignorance of the public, and while they generally pose as benefactors of mankind, are nevertheless beneath the contempt of every honorable member of the profession which they disgrace.

The World's Fair management made a serious mistake in admitting these people to the Electricity Building, thereby assisting them in the humbugging of the public, and giving to them more prestige and standing than they already had.

Those responsible for the blunder should have taken into consideration the fact that none of the promoters of these fakes would be admitted to membership either in a reputable medical society or in any of our electrical societies, and that their advertisements are not admitted either to reputable medical journals or electrical journals.

Placing these electro-medical fakes on the highest plane possible, they are on a par with quack medicines—they may be of benefit to certain people at certain times, but the manner of their sale, the extravagant claims made, and the slight foundation in fact for claiming any good whatever for them, furnish sufficient ground for pronouncing them a wholesale swindle on the ignorant public.

Men of common sense will go to a physician when they are ill, and follow his directions. And the only manufacturers of electro-medical apparatus worthy of confidence are those who sell their wares to physicians solely, and allow the physician to decide where they may and may not be of benefit to the patient.

American Institute of Electrical Engineers.

The following announcement is made from Chicago by Mr. Ralph W. Pope, Secretary of the Institute:

By request of the President, an informal meeting of the Institute will be held at the World's Fair Headquarters, Electricity Building, on Wednesday, August 23, 1893, at 8 o'clock P. M. This is intended to be strictly a social gathering, for the purpose of extending personal acquaintance between members who may be present during the week of the International Electrical Congress, August 21-26.

Members intending to be present are requested to notify the Secretary in advance at the above address, in order that they may be informed should any change in plans be found necessary.

Letters addressed in care of the Institute will be held until the arrival of those for whom they are intended, or forwarded upon request.

The rooms of the Institute are located in the south end of the gallery, and will be found a desirable resort for those who visit the Exposition.

Electric Lights for New York Central Trains.

For some time the New York Central Railroad people have been experimenting with a view to lighting their entire service by electricity. It is said that they have practically solved the problem, and that the new cars will all have an electrical outfit. The dynamo is carried in the baggage car, and is driven by belts from the car axles. An accumulator is also included in the outfit, which supplies the current when the train is not in motion.

ELECTRICITY.

The Popular Electrical Journal.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Electric Belts. The suggestion that the Jury of Awards at the Fair may pass by the exhibits of electric belts, hair-brushes, and the like, is not to be tolerated for an instant.

These fake exhibits must either be at once ordered out of the Electricity Building, or they must be passed upon the same as other exhibits and the results made public.

The fakirs themselves want their wares examined, and they have the same standing as any other exhibitor. They would, indeed, have first-class grounds for an action for damages if the jury refused to pass upon them.

More than this, the profession at large, which has been disgraced by the presence of these frauds, wants them to be examined.

It would be a piece of rank cowardice to adopt any other course, and we cannot believe that the authorities, who have stamped them as reputable by the assignment of space, will try to evade their responsibility by any such weak-kneed policy.

We know not what motive inspired their admission, but whatever it was, the exhibits are there and must receive consideration.

ELECTRICITY has given them consideration this week, several columns of it, and we shall still do them further honor later on. We shall endeavor to make it plain that the more truth there is in the claims of the venders of these belts as to voltage, amperage and internal resistance, the further are the belts removed from harmlessness, and the more dangerous they become in the hands of the ignorant.

But one of two lines of action remains for those responsible for their presence: they must be examined and passed upon regularly, or they must be removed from the building. We earnestly recommend the latter, however "unpleasant" might be the developments of such a proceeding.

……o……

Street Railway Power Plants. The performance of railway power plants of different types is the subject of an important paper read at the Chicago meeting of the American Society of Mechanical Engineers, and reproduced in abstract elsewhere.

The relative efficiencies of power plants using different kinds of equipments, such as large low-speed engines or smaller high-speed ones, condensing or non-condensing, direct driving or belting, etc., constitute an open question in engineering practice on which many and varied opinions obtain, but which has not been the subject of accurate comparative tests. The tests forming the subject of the present paper, while of considerable interest, fail to throw much light on this matter, as the plants in Minneapolis and St. Paul are not equipped with the class of machinery at present most in vogue for large stations, viz., the direct connected triple expansion engines and dynamos.

In regard to the plants tested, which consisted of two and three triple expansion Corliss engines with countershaft, and ten Westinghouse compound engines run non-condensing, the difference in efficiency was found to be slightly in favor of the former, as the Westinghouse engines were run at a somewhat lower steam pressure than the contract for the engines specified. At their normal pressure it is calculated that the latter would show an equal or better efficiency than the large engines, and the authors seem to favor the subdivided power plant on account of its more accurate regulation and the possibility of shutting down any number of engines according to the load so as to keep those in operation near their maximum capacity. The ability of the smaller engines in the line of close regulation is specially mentioned, it being found that they were capable of adapting themselves to a change of from a full load to a friction load in about four revolutions. It is to be noticed that the saving due to running the large engines at their rated load would be six and seven-tenths per cent. over the usual conditions of load.

……o……

What is a Floating Debt? There seems to be among men in the trade who are creditors of the General Electric Company a serious misunderstanding as to just what the term "floating debt" covers when applied to the liabilities of a corporation.

When the statement was made that the sale of four and a half millions of treasury assets had been arranged for to provide for the floating debt, ELECTRICITY was charitable enough to assume that this amount covered not only the loans which the company had made, but practically all of its merchandise bills as well.

Financial experts in Wall Street say that there is no precedent for using the term "floating debt" to cover merchandise bills or running expenses, and that in the absence of an explicit statement to the contrary from a responsible official of the company, the presumption is that the merchandise bills, etc., are still unprovided for.

This is certainly not the interpretation given to Mr. Coffin's statement by the trade at large, and, if correct, shows the company to be in a far worse position than was supposed.

If the last of the treasury assets were sold, even to pay merchandise bills, etc., it revealed an unsound condition—a remarkable condition for a company that has had $10,000,000 of fresh capital to spend in the first year of its existence.

But if these assets were sold to recoup two of the leading directors of the company who had advanced four millions of money and who were mentioned as the heaviest purchasers of these securities, it gives an entirely different aspect to the matter.

Accepting the interpretation of the experts, suppose that two creditors of the company had accounts against it for merchandise bills aggregating a million dollars. What prospect would there be of their getting the money?

The company cannot be earning money, and the plan of finance which it has adopted seems to call for the payment of dividends as long as the money can be raised by whatever method, and utterly without regard to the laws of conservative financiering.

Before these treasury assets are allowed to leave the treasury, a clear and explicit statement as to the use which is to be made of the proceeds should be demanded.

Where Has the Money Gone?

The first statement of the General Electric Company, filed at the Stock Exchange at the organization of the company, showed that $29,847,100 of common and $4,024,400 of preferred stock had been issued. There was reserved for future delivery against certain outstanding shares of the three underlying companies $612,900 of common and $227,600 of preferred, which the company was authorized to issue. There has been issued to date $30,459,700 of common and $4,251,900 of preferred.

There have been issued and sold $10,000,000 of debenture bonds, which, by the way, are a preferred obligation as to dividends but not a lien on the assets.

The company assumed debts of all kinds at its organization, according to its own statement, of $9,373,520.98. This debt had been reduced on January 31, 1893, to $7,961,925.92, or by $1,411,595.06.

When the company applied for the listing of its bonds at the Exchange on July 6, 1892, it made the following statement:

> "A million and a half of the proceeds of these bonds has been used toward extinguishing the floating debt, and it is intended to use the balance for the same purpose."

The first part of this statement harmonizes with the figures given above as to the reduction in debt of all kinds for the first eight months.

But it is evident that the "intention" to apply the remainder of the proceeds from the bond issue in like manner was changed somewhat, as the company, which has claimed to be making large profits, confesses now, a year later, to a "floating debt" of over $4,000,000.

This leaves $8,500,000 of the proceeds of the bond issue unaccounted for.

Where has it gone?

On April 26 last we showed in these columns, from two of the company's own statements made eight months apart, that it had lost during that period $5,922,003.44. Maintaining that rate, the company would have lost up to August 1st for the fourteen months $11,842,006.02.

This, we believe, solves whatever mystery there may have existed as to where the money from these bond sales has gone. It has gone to maintain a losing business, in the hope on the part of the officers that successful patent litigation would yet give them a monopoly by means of which they could pull through, and make up for the losses of the first year.

……o……

We wonder if the committee which has been investigating General Electric's financial condition solved the mysteries of the relations between the Jenney Electric Light Company and the Fort Wayne Electric Company. If so, what value did they place upon the stock of the latter company? It is said that the entire plant at Fort Wayne is owned by the Jenney Company, and that the Fort Wayne Electric Company is merely a paper company, like many others whose stock has been so successfully manipulated in the making up of the Trust scheme.

……o……

Our constituents could not fail to be interested in the Tracts prepared by Mr. G. Wilfred Pearce. They are worth reading.

San Francisco for the Convention.

The question of the meeting place for the next Annual Convention of the National Electric Light Association will soon come up for settlement by the executive committee.

There is little doubt that the present business stagnation will have passed away by the first of the year, and it seems to us that the Convention city should be chosen this time with especial reference to the advantages it offers, in way of location, for creating a boom in the electrical industry. If this consideration governs the choice of a meeting place, there are obviously but two sections of the country to be considered—either the South or the Pacific Slope.

One important point to be considered should be the standing of the newspapers of the various towns under discussion. The good which the Convention can accomplish from a *business* standpoint depends almost wholly upon the publicity given to the proceedings through the local papers. Therefore a town having first-class newspapers should be chosen. Either Atlanta or San Francisco would, it seems to us, fulfil all the requirements admirably.

The fact that there is to be held in San Francisco, from January 1 to June 1, an International Exposition, which cannot fail to attract a large number of visitors to that city from all parts of the West, Northwest and Southwest, gives to San Francisco an important advantage over all other cities for this year.

That prince of hustlers, Mr. M. H. de Young, is the Director-General of the California Exposition, and it cannot fail to be successful.

San Francisco's hotel accommodations are ample, her newspapers are among the best in the country, and her location is unsurpassed *from a business standpoint.*

A rousing Convention in San Francisco, with the accompanying publicity given to the proceedings by her many newspapers, could not fail of producing a decided boom in all branches of electrical development in the West, where the greatest possibilities now lie.

……o……

The World's Congress of Electricians at Chicago next week will, without doubt, be the most representative assemblage in the history of the art. The august delegates will see, when they visit the Electricity Building, exhibits of electric belts, electric hair-brushes, electric headache cures, electric insoles, and many other electric humbugs, standing as far as is in the power of the authorities of the Fair to assist them to stand, upon exactly the same basis as the proudest products of the genius of Faraday and Siemens, of Morse and Bell, of Thomson and Weston, of Edison and Brush.

……o……

The only reasonable plan for the enjoined lamp makers to adopt is to open their factories as usual on the morning of November 11, 1893, proceeding on the assumption that the Edison lamp patent has expired.

……o……

A well posted electrical man stated last week that he had $100 laid away with which he expected soon to be able to buy ten shares of General Electric.

The Joliet Prison Contract.

We trust that the last has not yet been heard of the disgraceful proceedings attending the award of the contract for a lighting plant at the Joliet (Ill.) Penitentiary, notwithstanding that the papers have been signed.

The State of Illinois has courts which were created to secure justice to all her citizens, and there is abundant reason for supposing that if the courts are appealed to they will take a different view of this matter from that enunciated by Gov. Altgeld and put in practice by his direction.

The latter has treated with contempt a large number of reputable manufacturing companies, who all had a legal right to a respectful hearing.

The National Water Tube Boiler Company and various electrical companies, including the Waddell-Entz Company, the Westinghouse Company, the Standard Electric Company and the Siemens & Halske Company, have especial grounds for complaint, and they should lose no time in going into court with the matter.

Proof of actual bribery of officials, or of a divide which is the equivalent, would, of course, be almost impossible to obtain. But that bribery in some form was a part of the job is the only fair presumption.

The suspicion of having received money to influence his action does not attach to Gov. Altgeld. He is beneath it. He is an ignoramus and a blatherskite, a weak-minded egotist, who takes evident pleasure in using the high power of his office in direct opposition to decent public sentiment. The party that elected him has disowned him, and the court would begin on the presumption that Gov. Altgeld was in the wrong.

We have referred to the fact recently that when the General Electric Company was in the throes of despair, and likely to be thrown into bankruptcy, neither sympathy nor regret was exhibited in the trade. The Joliet incident shows why this is so.

The General Electric Company is not despised because it is getting more than its share of the business, for it has only got in the past year about 50 per cent. of the business which might have been expected to come to it.

It is despised because its roguery and dishonesty are displayed wherever a contract is to be let.

It will yet be the pleasure of Electricity to record, as it will of the trade at large to read of, serious disaster to this sham Trust, which does not apparently know what it means to conduct business on an honorable basis.

The death of Col. L. W. Burnham removes from the electrical trade a man who was an ornament to it, a man of great business ability and endowed with a high ideal of business honor.

The few who were favored with an intimate acquaintance with him will feel a sense of personal loss not soon to be repaired.

No Exception.

"It has for about fifteen years been Mr. Edison's chief misfortune that newspaper men fail to maintain their mental equilibrium when writing of him."—Electricity, *July* 12.

"Ah! potent wizard, you shame the records of the Arabian nights and the fabled glories of the East. We must look from these to the pictured paradises of the blest, where the gems are lit by deathless fires, and where fountains and foliage give forth eternal harmonies."—*A. and W. K. L. Dickson in Cassier's Magazine for August.*

General Electric.

What is Said of It Nowadays.

President Coffin of the General Electric Company says that, as far as he knows, there is no truth in the statement that application has been or is to be made at Providence by a Trust company which holds General Electric bonds for an order by the court to prevent the company from using assets in its treasury to pay off its floating debt.

The point has been raised yesterday that the sale of Treasury assets by the General Electric Company would interfere with the rights of the debenture bondholders. The clause in the debenture bond mortgage bearing upon the matter follows:

"The company agrees with the holder that it will not at any time mortgage or pledge any property or franchises belonging to it at the date hereof without also thereby expressly securing the principal and interest of this debenture bond [if outstanding at the time any such mortgage or pledge shall be made] ratably with any and all other indebtedness secured by such mortgage or pledge. And in the event of such mortgage by this company, the holder hereof shall, upon demand, be entitled to receive in exchange for this debenture bond a mortgage bond for the same principal sum, but bearing interest as therein expressed."—*Recorder.*

A Curious Property.

The performances of this curious property demand a moment of further attention. During the extreme depression, about ten days ago, the price touched 30 and kept persistently in the neighborhood of 35. Under the influence of the upward twist, the stock kited upward and crossed 50, and looked as though it were pluming itself for a fresh flight.

It was pretty well understood that the improvement had been brought about by Mr. Keene, acting as the market representative of Drexel, Morgan & Company.

There was a bigger crowd yesterday in General Electric on the floor of the Exchange than in any other stock. The way in which the quotations acted showed conclusively that there was something the matter. Practically, there was no market for the stock, and under offerings of stock the market shrank away as though it were burned.

The truth of the matter is that the recent financial policy of the management, taken in connection with the revelations of the condition of the property and the mystery that is faithfully observed concerning its operations, has destroyed everybody's confidence in its inherent merit. It will be remembered that late in June the company declared a quarterly dividend of 2 per cent. on the common stock, and this required for its payment on August 1 about $600,000.

During July was presented the curious spectacle of the company's agents hustling around the Street on a wild voyage of discovery for money wherewith to retire the floating debt which was pressing for payment. Finally it was decided to sell out the treasury assets and raise the necessary money, which amounted to $4,000,000. This sale of treasury assets was the second proceeding of the kind, and when it was all over it was believed that the company's treasury was practically gutted.

The idea of a company paying a dividend, and at the same time appearing in the market as a desperate borrower of funds, is analogous to the performance of the irresponsible prodigal who blows his friends off to a Delmonico dinner and turns up at a pawnbroker's the next day and pledges his jewelry in order to pay for it. If the company had passed the dividend and conserved its resources, it might have failed of a momentary and feverish prestige, but it would be enjoying now a great deal better reputation than it does, and its stock would probably be selling from 10 to 15 points higher.

As the matter stands, Wall Street and Wall Street's customers will not believe anything favorable that is said concerning it, and regard it as practically valueless, and feel that it will sell as far down as it has ever sold before—that is to say, 10 points below the present figure.—*Daily America.*

Apropos of General Electric affairs, what a marked contrast there is between official utterances now and a month or six weeks ago. Then everything was blooming and rosy, but now Drexel, Morgan & Company actually say that they have been obliged to make sacrifices to prevent the company falling into a receivership. It is the same old story, the truth about a concern is never told until the crisis comes.—*Boston Commercial Bulletin.*

Legal Notes.

The sheriff has taken charge of the office of the Equitable Manufacturing and Electric Company at 44 Broadway and the factory at 611 West Thirty-sixth street on an attachment obtained by Cravath & Houston for $29,540 in favor of Wendell Goodwin for money loaned. The company was incorporated several years ago with a capital stock of $1,000,000. Cornelius Fellowes is its president.

Attorney-General Hensel, after hearing arguments pro and con by leading lawyers, has refused the writ of quo warranto requested by certain citizens of Gettysburg to deprive the trolley line of its franchises on the battlefield. The Attorney-General decided all the points involved in favor of the trolley company.

In order to satisfy a judgment of the court the machinery and electrical apparatus of the Chicago Electric Motor Company was sold at public auction last week. The apparatus consisted of a lot of new fan motors, which was the principal article built by the company.

A California Exposition.

Something for Electrical Manufacturing Concerns to Think About.

An International Exposition will be held at San Francisco, Cal., U. S. A., from January 1 to June 30, 1894. The site of this Exposition is located in Golden Gate Park and will cover an area of about 100 acres. There will be five principal buildings for the Midwinter Fair, viz.: *(a)* Manufactures and Liberal Arts; *(b)* Agricultural and Horticultural Hall; *(c)* Mechanical Arts; *(d)* Fine Arts and Decorative Art; *(f)* Administration building. Applications are being received daily for separate and special constructions such as: State exhibits, restaurants, reproductions, side-shows, etc.

M. H. de Young, Vice-President of the National Commission, World's Columbian Exposition, Chicago, will act as Director General and President of the Executive Committee of the Winter Fair; the other members of the administration and officers are: Irwin C. Stump, vice-president; P. N. Lilienthal, treasurer; Col. A. Andrews, R. B. Mitchell, Hon. Eugene J. Gregory, Sacramento; Jacob H. Neff, Colfax; Fulton G. Berry, Fresno; J. S. Slauson, Los Angeles; Alexander Badlam, secretary; R. Cornely, assistant director general.

Information for intending exhibitors, maps of the grounds, buildings, etc., may be obtained by applying to the Department of Publicity and Promotion, California Midwinter International Exposition, Mills Building, San Francisco, Cal.

Personal.

Mr. Morris W. Mead, of Pittsburg, was enjoying an Eastern trip last week, and spent a day in going over the police and fire-alarm services of Brooklyn as guest of Mr. F. C. Mason.

Dr. Robert Newman, of New York, informs his friends that he will be in Chicago during the month of September, where all communications should be addressed to him, care Franklin H. Martin, M.D., Venetian Building.

Mr. O. W. Meysenberg, President of the Siemens & Halske Company of Chicago, spent Sunday at Manhattan Beach.

Mr. Henry Goebel, although nearly eighty years old, is still in vigorous health, and has recently travelled from New York to Chicago.

Bids Wanted.

Bids will be received up to Thursday, September 7, for supplying to the Watervliet Arsenal, Troy, N. Y., an electric lighting and power plant, including two traveling cranes of 60 and 30 tons capacity each, 12 H. P. and 15 H. P. motors. Specifications and all other information can be had on application to Major Isaac Arnold, Jr., Ordnance Department, U. S. Army, Commanding.

Practical Aspects of Low Frequency Electrical Resonance.*

BY M. I. PUPIN, PH.D.

DISCUSSION.

The President—Gentlemen, you have heard Dr. Pupin's admirable paper. Does the Institute wish to make any remarks on it?

Mr. Tesla—Gentlemen, I do not know whether I can contribute in any way to the clear and skilful exposition which Prof. Pupin has made of the phenomena of resonance. They have been familiar to me for a long time. In fact, two or three years back I began to work on lines in which an observation of some of the rules advanced by Dr. Pupin is an absolute necessity, and one of the reasons why I have only reluctantly consented to deliver a lecture on some high frequency phenomena, which I have shown on two or three occasions, was that I felt inadequate to the task, because in every experiment one has to depend on certain delicate balances, and one cannot always feel sure of succeeding in the experiment, especially in a public lecture. Dr. Pupin has admirably succeeded in performing before an audience a number of difficult experiments. I saw this marvellous experiment with the iron core, performed by him last week, I believe, and I have been much impressed with the importance of the molecular condition of the iron. Any observation relating to the iron must be of interest, as it may lead to valuable results, and since I am called upon, I may mention a few of my own experiences, though they might not be in direct connection with the subject treated by our lecturer. About two years ago I observed a curious effect which I abstained from mentioning so far, because I could not explain it to my satisfaction. It was this: I had an alternator of high frequency operating an induction coil. The secondary of this induction coil was connected to a Cardew voltmeter, and I had made the windings so as to bring the deflection into the best range of voltmeter. A condenser was connected to the alternator. I varied the amount of iron in the core of the coil and observed the rise in the electromotive force. As iron wires were added the electromotive force would continuously rise up to say 100 volts. Then there was a point at which when I added a few iron wires the electromotive force fell off about two volts. A further addition did not make any change whatever. I observed that effect repeatedly and repeatedly, but could not satisfactorily explain it. Now in the light of the experiment of Dr. Pupin and with the knowledge we presently possess, I cannot think else than that there was something of the same nature in the phenomenon. The delicate balance which, as Dr. Pupin has shown, can be easily upset by the introduction of a single iron wire in the coil, reminds me of an experience with a machine which was regulated by means of an "auxiliary or third brush," a very interesting device, but owing to the extreme sensitiveness not quite commercially available. The idea is to take a dynamo having the field magnet in series with the circuit and connect a point of the field coil or of the external circuit by means of an auxiliary brush with a point of the commutator. The sensitiveness obtainable by this means can be anything one chooses, and so great can it be made that the slightest disturbance on the machine may upset the whole circuit, and if there be arc lamps in the circuit, for instance, one may barely tap a lamp thus causing an imperceptible movement of the carbon rod, and all the lamps will go out if the auxiliary brush is in such a position and the field coil so connected that the shifting of the neutral line is an *accumulative* effect. In order to improve the action of the lamp mechanism I had the machine constructed in such a way as to give periodic impulses of a certain intensity, which produced a noticeable vibration in the field magnet, and so well did I notice the machine, operating it day and night (for at that time practically all my life was passed in the laboratory), that I could tell from these vibrations, by holding an iron bar in a certain position to the field magnet whether the machine was working properly. I noted then that sometimes all of a sudden the lights would go out. After this had occurred about a dozen times, I recognized that when I came with the iron bar near to or touched the field magnet I disturbed the field enough to displace the neutral line and the lights would go out because the machine would discharge itself.

---

* A lecture delivered at the Tenth General Meeting of the American Institute of Electrical Engineers, Columbia College, New York.

Another observation which I may mention about the iron came to my attention in 1886. I then made some experiments on a so-called "thermo-magnetic" generator. This *nihil bonum* principle had no doubt occupied the time of many inventors. I had attacked the problem in quite a different way, sufficiently promising to justify an engineer to enter into an investigation and see what could be done. The method I followed was to enclose in a stove an iron core which closed the circuit of a magnet, this iron core consisting of a box of iron with small sheets of iron running through offering an enormous cooling surface. I used steam passed through the interstices to cool down the iron. My expectation was that the iron would just cool down a little so as to become magnetized when steam was admitted by means of a valve. The circuit of the magnet would then be closed and the valve was automatically shut, thereupon the iron was again heated and demagnetized. To a certain measure the valve worked well, but the vibration was too slow. It generally so happened that when the steam was admitted it would be decomposed and a greenish flame would shoot out of the stove. This indicated that the temperature of the iron was too high. I would bring the temperature of the iron down by admitting two or three times the steam in pressing upon the valve. Every time I did this the flame would shoot out of the stove. Then there would be a miss for about two or three times in succession, no flame appearing, the iron being cooled sufficiently, but upon doing it the fourth or fifth time, which took about a second or two, the flame would shoot out once more. I could not explain this phenomenon. A little later I obtained the classical work of Dr. Hopkinson on the recalescence and other properties of iron at high temperatures and plainly saw that it was recalescence. The temperature must have just been varied around the critical point. Still another fact which I recollect to have observed in experiments with high frequency currents is that an iron rod or wire, when an arc is formed through it, burns and sputters with violence, considerably more so with high than with low frequency or direct currents. It is possible that the effect is solely due to the magnetic properties of the iron, but it might be more or less produced by the increased resistance and consequently more intense heat evolution. With great magnetizing forces an iron wire inserted in a high frequency coil is instantly brought to a high temperature. This I have before pointed out, but Dr. Pupin has observed a similar thing with low frequency currents when a condenser is in circuit and resonating action takes place.

I wish to say in regard to converting to high potential, starting from a low potential dynamo, by simply combining capacity and self-induction with the circuit, that is, by resonating action, I have in my paper, which has just gone to print, dwelt specifically upon converting in this manner, and in fact I am delighted to see that Dr. Pupin has taken the views he has here expressed. My usual method was to attach to the alternator a coil consisting of a great number of sections, and to associate adjustable capacity with the coil, and then to vary the number of sections and the capacity until the best resonance was obtained. This obviated the employment of a secondary coil; but I found that in adjusting it was preferable to convert first the low tension currents to such a high potential that the necessary capacity would become extremely small, so as to be reduced merely to that of two small plates, because of the great difficulty of producing a condenser of large capacity adjustable by extremely small steps, which it is necessary to employ when the potentials are small. If we convert to a potential of say 50,000 volts then the capacity becomes very small, and we can just use a few plates immersed in oil, which permit varying the capacity by extremely small degrees, and without sudden, disturbing breaks. This is one of the reasons why I have always preferred to convert in a secondary circuit. The adjustment by varying self-induction by means of an iron core is, as Dr. Pupin's experiment now plainly shows, not always practicable. I think that the experiments we have seen here demonstrate that we are as yet far from having studied the properties of iron thoroughly, and that much remains to be done in this direction. I agree with Dr. Pupin that the condenser, which I had thought was going to be of great help in alternating work, does not really appear to have a great future in connection with apparatus with large iron cores, as motors or transformers, because of the action of the iron, and for one more reason besides, namely, that we can, especially if we have a high potential or high frequency, always wind a coil so as to take up just enough capacity to be in resonance with the circuit, in so far as the iron core will permit.

I only have to add, that I sincerely thank Dr. Pupin (which probably is the wish of all), and that I have profited very much by his lecture, which is a clear and precise exposition of the principle, as well as a most interesting experimental demonstration of electrical resonance with a dynamo machine.

[Adjourned.]

COMMUNICATED AFTER ADJOURNMENT BY DR. PUPIN.

Mr. Tesla is very kind and generous with his compliments. I do not think, however, that his statement of facts is free from ambiguity. He states that the phenomena of resonance which I have discussed were familiar to him for a long time. My discussion referred to low frequency resonance, whereas Mr. Tesla has, I think, always worked with high frequency apparatus, so that his familiarity with low frequency resonance, the subject which I discuss, is probably not based upon his own experimental investigations. At the time when the Ferranti effect called forth so much valuable discussion in England, Mr. Tesla[*] contributed some remarks to this discussion, which remarks culminated in the following: "The writer looked for a case of resonance,[†] but he was unable to augment the effect by varying the capacity very carefully and gradually, or by changing the speed of the machine. A case of pure resonance he was unable to obtain. When a condenser was connected to the terminals of the machine . . . the capacity which gave the highest E. M. F. corresponded most nearly to that which just counteracted the self-induction with the existing frequency."

Mr. Tesla states also in this article that the highest value of the augmentation of the potential which he was able to obtain by connecting a condenser in series to the armature of his high frequency (10^4 periods per second) machine wa *only four or five times the impressed* E. M. F. What then could Mr. Tesla infer from this result in regard to resonance effects with low frequency? Certainly nothing that was encouraging.

At no other time did Mr. Tesla, as far as I am aware, approach the subject of resonance any closer than in the article just referred to.

Perhaps Mr. Tesla means that he was acquainted with the phenomena of low frequency resonance which I discussed from the investigations of other men, like Fleming, Kapp, Glazebrook, Swinburne, Lodge, Blakesley, etc.[*] I appreciate fully the value of the labors of these men, but still I fail to see a very close relation between their work and mine, excepting in one point, and that is, that they as well as I have shown theoretically that it is possible to produce a high rise of potential by a combination of self-induction and capacity. *I have shown it experimentally also.* But I think that I have pointed out very clearly in the course of my lecture that I did not regard the resonant rise of potential as an end, but simply as a means to an end, the end being harmonic analysis of E. M. F.'s behavior of iron and dielectrics under the inductive action of resonant currents of low frequency, weeding out of harmonics by means of resonance, etc. With these phenomena Mr. Tesla does not appear to be familiar, either from his own experimental investigations or from investigations of others, excepting those phenomena which Dr. Duncan had investigated some time before me and which I mentioned in the course of my lecture.

---

[†] The meaning of this term Mr. Tesla did not explain.

[*] See *London Electrician* for 1889, 1890 and 1891, also "Fleming's Alternate Current Transformer," Vol. II., p. 401.

Users of Infringing Lamps Sued in Detroit.

The Edison Electric Light Company of New York and the Edison Illuminating Company of Detroit have begun suits in the United States Circuit Court in that city against the Huyett & Smith Manufacturing Company and the Detroit Confectionery and Fruit Tablet Company to restrain further infringement of the Edison lamp patent and to collect damages for past infringements.

The Congress Special.

Additional Arrangements for the Pleasure of its Patrons.

Mr. W. A. Grant, General Manager of the Niagara Falls Park and River Railway, has extended an invitation to the Congress delegation, which is to leave New York on the special train Saturday evening, August 19, to take a ride over his road on Sunday morning, before the train proceeds to Chicago from the Falls. The invitation has been accepted by the management.

The road is operated by Niagara water power, and has a route of twelve miles in view of the Falls and Rapids. It was described at some length in a recent issue of the *Electrical Engineer*.

Receiver for the Pueblo Road.

Mr. Sunny's Famous Deal Goes Wrong.

The Pueblo City Railway Company (Consolidated), owning and operating five separate lines of electric roads in Pueblo and suburbs, has passed into the hands of a receiver, H. E. Chubbuck having been named by the United States Court to act in that capacity.

This road was equipped with Thomson-Houston apparatus, for which $175,000 in second mortgage bonds were taken in payment.

It was eventually learned that there was a large floating debt hanging over the road, which was, further, losing money rapidly. Finally to protect themselves it is understood that the Thomson-Houston people bought up nearly all claims against the company, and installed as manager Mr. Chubbuck, who has made an unsuccessful effort to pull the road out of a hole.

Mr. L. W. Burnham.

When in February of the present year we published an illustrated historic account of the rise, growth and present prosperity of the Electric Gas Lighting Company of Boston, including a brief biographical sketch of its vice-president and general manager, whose name appears at the head of this article, we little thought that ere long it would become our sad duty to pen an obituary of one who was widely known, universally respected, and whose life had been varied, useful and successful. Yet so it has proved to be. Col. Burnham, after two weeks' sickness, was called to his rest on Wednesday last, at his pleasant home in Dorchester, in the presence of his wife, daughters and son. For some time past he had been contemplating a visit to the World's Fair, accompanied by his youngest daughter, the day for their departure having been fixed for Wednesday, July 26. During the night previous Col. Burnham was seized with an attack of what proved to be partial paralysis, rendering him semi-conscious, with the loss of control over his muscular organization. At first his physicians believed he would soon rally, though they predicted even in that event that he would require care and attention for a long time to come. Their belief, however, was not sustained, for he had a relapse and gradually sank until the end came, calmly, peacefully, on Wednesday last.

Col. Burnham was only in his sixty-third year—by no means a great age—and he might have been expected, in the ordinary course of life, to enjoy many more years of usefulness. This, however, was scarcely expected by those who knew him most intimately. His absorption in the business he built up, which is a lasting monument to his energy and industry, had been a severe tax on his active mental faculties for many years; and so completely did he devote himself to the responsibilities of his position that his health had given way several times during the last two or three years. More than once have his physicians warned him when treating him for physical ailments that he should be careful lest his mental powers should give way under the severe strain he was subjecting them to. That these warnings were the utterances of well-grounded fears and indications subsequent events proved, for those who have known him intimately and been associated with him in business some months ago discovered that there were unmistakable symptoms of his mental powers being somewhat impaired, manifesting themselves in eccentricities of manner unusual with Col. Burnham when in his own true and genial form. As his final sickness showed, his brain was unequal to the task imposed upon it and he succumbed. The funeral service was held at the home of the deceased, where his remains lay—his countenance placid and serene as if he had dozed off into sleep—enclosed in a black draped casket embowered in foliage and appropriate floral emblems. Many friends and acquaintances were present as a mark of respect to the memory of one whom to know was to esteem. The services were impressive and beautiful.

Subsequently the remains, accompanied by Mrs. Burnham and family, were removed to Palmer, Mass., where they were interred in the family lot. W. S. K.

Association of Edison Illuminating Companies.

At the annual meeting of the above Association in Chicago last week, the following officers were elected for the coming year:

C. A. Edgar, president; G. H. Finn, vice-president; W. S. Barstow, secretary; Wilson S. Howell, treasurer. Executive Committee: John I. Beggs, chairman; F. P. Gilbert, E. R. Weeks, Wm. D. Marks, J. W. Pryor, C. L. Edgar (ex officio).

The retiring officers were thanked by a vote of the Association.

The next meeting of the Association will be held in Boston.

ALL VISITORS to the World's Fair will be welcome at the booth of ELECTRICITY, Section Y, Northwest Gallery, Electricity Building.

The Joliet Contract.

Crookedness Carries the Day, and the General Electric Company Gets the Contract.

Contracts for the electric light and power plant at the Joliet Penitentiary have been awarded by the Commissioners. The electric light plant was awarded to the General Electric Company for $51,000.

The result of the awarding is not only interesting to the electrical fraternity, but has also aroused considerable interest in the political parties. As related in this paper some weeks ago, several of the Chicago agents for different electrical concerns became aware of the fact that a contract was to be let. By various schemes some of the agents were able to secure specifications and drawings. Five of the representatives put in bids for the apparatus called for in the specifications, or apparatus which they manufactured as nearly like that called for in the specifications as was possible. Upon examining the General Electric Company's proposal for the plant, it was discovered that their bid was not in accordance with the specification which the other companies were expected to base their figures on. This fact was more conspicuous when it was discovered that the plans were drawn up in the General Electric Company's own office in Chicago. The main difference between the propositions made by the General Electric and the other companies was in one machine and a large switchboard being left out of the former company's bid.

In order that the actions of the Commissioners and Warden Allen might be brought directly before the Governor, a number of telegrams were sent to him, asking when he could be seen by the representatives of the companies outside of the Trust. Some of the agents formed their complaints into a petition asking Governor Altgeld to investigate the proposed manner of letting the contract.

Gov. Altgeld replied with a number of misstatements, showing conclusively his ignorance of the whole subject of electrical companies and their products and his utter incapacity to appreciate the question of propriety involved in the controversy. The Governor's statement closed as follows:

"Having spent nearly three weeks in investigation and in hearing statements the Commissioners and the Warden found that the concerns that were making all of the fuss did not handle the kind of machinery the State wanted. I said to them that the newspapers cannot run the penitentiary. They are not responsible for its management, and we are. If there is anything to be gained or to be saved by advertising, I wanted them to advertise, otherwise let these contracts at once and waste no more time; I want that plant completed before cold weather sets in. I therefore directed the Warden to proceed at once to close these contracts, being convinced that at present it is the best we can do."

Mr. C. A. Daigh, of the Siemens & Halske Company, makes the following reply to the Governor's statement:

"He states that he told us that he would investigate the matter at once. There is no truth in this statement, as we have never heard from him in any way, shape or form up to the time his interview was published in the *Herald*.

"His statement is not correct when he says that the Siemens & Halske Company could not furnish the belted machines, as we manufacture that type of machine, and are preparing to supply it with reasonable promptness.

"The statement that we had no plant in operation in the West except at the World's Fair is certainly far from correct, as if he had taken the trouble which he states he has, to thoroughly investigate the matter, he would have ascertained that right here in Chicago at the Auditorium Hotel we have in use a very much larger plant than the one proposed to be installed at Joliet, and furthermore where we are replacing General Electric Company's machinery.

"As to charging the Commissioners with dishonesty the word was first used by the Governor himself, therefore the public may draw their own inference.

"If the Governor really desires to act in the best interests of the State, I would say this much—that if he will re-open the matter I will guarantee that he will not only secure lower bids for the complete outfit than he has, but if he will place the matter in the hands of competent parties, the State will be the gainer in many thousands of dollars."

The Traction Company is All Right.

It is announced that the Traction Company of Philadelphia, which has been hampered somewhat in its operations this summer from lack of funds, has negotiated a loan of $2,000,000, and will carry out all its obligations promptly, including many improvements to its system.

Boston Notes.

At North Abington, Mass., a few days ago, a gang of men in the employ of the electric street railroad company were about to begin laying rails across the track of the Old Colony Railroad, when the officials of the latter road becoming apprised of the fact dispatched a locomotive to the scene and kept it running up and down the track rendering it impossible for the rail-layers to work. After this had continued for some time the officials of the two roads held a consultation, the outcome of which was that the work was suspended, although the electric railway men still contend that they have a legal right to cross the Old Colony tracks.

Work has been suspended on the branch roads of the Lowell, Lawrence and Haverhill Street Railway, in order that the entire force may work on the completion of the main track, between Haverhill and Lawrence, that is to be opened in September.

The factories of the General Electric Company at Lynn are running to fill cash orders alone, the directors having determined during the present financial stringency to do no more business on their usual lines, that is, putting in railway and lighting plants at their own expense and holding a lien on them until such times as local capital can be influenced to purchase said plants or subscribe for stock. Of course, many hands have been laid off and the rest are working short time.

Last Friday the new electric railway between Abington and Rockland, Mass., was opened amid great enthusiasm, and no less than 2,790 passengers were carried the first day, though the two towns are but small in population. It is expected that the new road will give the district a big boom.

During the past year the mails between Camden and Rockport, Me., have been carried by electric cars, improving the service very materially. The citizens of those and neighboring towns who have thus been well served are up in arms because the postal authorities have let the contract for the coming year to a carrier who has returned to the old style of using horses for carrying the mails, thus delaying their delivery by several hours.

The novel and beautiful electric fountain which is to be erected in the Frog Pond on Lynn Common will be constructed by the Franklin Electrical Company of Kansas City, Mo., whose design has been accepted, and who has bid $2,000 for the entire work. When completed it will be the most attractive work of its kind in New England, and a striking feature of ornamentation on Lynn Common.

Some time ago the directors of the Boston and Newton Street Railway Company petitioned the State Board of Railway Commissioners for authority to increase the capital stock of the company by $40,000, to enable them to make certain necessary extensions, also to fix the exact price per share for the new stock. The commissioners, after some deliberation, have granted the requisite authority, and determined that the shares shall be $100 each.

There is an increasing demand for a first-class efficient brake, one that will always work with no possibility of failure, on electric cars. Of late there have been several somewhat serious accidents by brakes refusing to work at the right time. The most recent of these mishaps occurred in Malden on Thursday, when, in descending a somewhat steep incline, the motorman discovered his brake wouldn't act. A short distance ahead was a sharp curve on top of an embankment twelve feet high. The car had a number of passengers inside. One by one they jumped as the car gained speed, and were each bruised more or less, including both motorman and conductor, who stuck to their posts. To add to the approaching danger a loaded car was coming in the opposite direction. In taking the curve the now empty runaway car jumped the track and went down the embankment, being reduced instantly to matchwood. Had it kept the track and collided with the loaded car, there would have been a frightful loss of life.

There was a lively meeting of the Cambridge Board of Aldermen, Thursday evening, arising out of a message sent by Mayor Bancroft, in which he vetoed an order passed a week ago by the aldermen, granting authority to the West End Railroad Company to lay electric car tracks along Brattle street, one of the high-toned streets of the University City. The subject has been under discussion for a long time, the residents of that thoroughfare having protested against the classic privacy of their neighborhood being ruthlessly invaded by the supposed vandalistic electric cars. The Mayor's veto was sustained by many citizens, and finally, after a warm discussion, by the aldermen too, who, however, proceeded to pass a fresh order of similar import, which is pretty sure to be vetoed as was its predecessor. The movement in favor of a storage battery road in Cambridge is likewise blocked for the time being.

The notification to 700 of the employees of the General Electric Company a few days ago that their services were no longer required was an error according to Mr. E. W. Rice, Jr., general superintendent of the factories. It was intended only to lay off 300 men, and it is hoped that there will be no further necessity for discharging more hands. It is intended to reduce the working hours of those still employed, should occasion demand, rather than lay off more men.

The Schuyler Electric Company of Middletown, Conn., has had to reduce its staff of employees nearly one-half owing to the present stringency in finance.

From Monday next the entire clerical staff connected with the motor, mining and lighting departments of the General Electric Company will be located at 44 Broad street, New York, the New England district offices remaining as at present, at 620 Atlantic avenue, Boston.

Canadian Notes.

The St. Clair Tunnel Company are considering the advisability of adopting electric transit through the tunnel, and have secured estimates from the Canadian General Electric Company for such an equipment. The smoke from the engines is having a most serious effect upon the interior of the tunnel, and Chief-Engineer Hobson is greatly concerned over the matter. The question of cost, however, is yet to be overcome before any definite action is taken.

The first car was run over the Peterboro Electric Railway last week, and the inauguration of the service was in every way satisfactory. The Canadian General Electric Company had the contract for equipping the road, which promises to be a most paying concern.

D. Thompson, of the Hamilton Electric Light Company, has severed his connection with that institution. Mr. Thompson has been in charge for several years past, and was formerly connected with the Royal Company of Montreal. He has a high standing in Canada as a capable working electrician.

The death of Mr. T. Griffiths, late Manager of the Hamilton Street Railway, has removed a most capable and popular man, whose loss is widely felt. He has been succeeded by his brother.

Great preparations are on foot in connection with the Convention of the Canadian Electrical Association to be held in Toronto next month. A great number of papers are in course of preparation by capable members of the Association, and a most attractive programme is being prepared for the visitors. One day will be devoted to a trip across the lake, where the Queenston Power House of the new Niagara Electric Railway will be inspected and the tunnel on the American side. A ride over the new road to the Falls and Chippewa will also be taken in.

The two arc light companies in London, Ont., have been recently acquired by a syndicate of Toronto capitalists, who propose spending $30,000 or $40,000 in remodelling the plant, introducing the incandescent light and an electric railway. A new power house is in course of erection, and a very favorable franchise has been secured from the city.

D. Thompson and Geo. Black, of the G. N. W. Tel. Co., Hamilton, have been invited to take part in the Electrical Congress which will meet in Chicago this month. D. Keely, Deputy Superintendent Government Telegraphs, Ottawa, has also been invited to take part.

The cable between St. Paul's Island and Meat Cove has been interrupted for the last two weeks. It is reported to the Public Works Department that the steamer Harlaw is responsible for the interruption, she having, it is alleged, fouled the cable in one of her recent trips to Newfoundland. The line will be repaired as soon as the services of the Government steamer Newfield can be obtained. The Newfield is now repairing the cable between Gaspé and Magdalen Islands.

General News.

What is Going on in the Electrical World.

McKeesport, Pa.—The Versailles Traction Company has been granted the right to lay its track in Locust street.

Binghamton, N. Y.—The Binghamton Electric Company has just added $12,000 worth of new machinery to its plant.

Batavia, N. Y.—The board of aldermen have deferred the matter of opening the bids for the new electric light building for two weeks, or until the 22d inst.

Lafayette, Ind.—The Physicians' Electrical Supply Company of Lafayette has assigned to Isaac Russell. Inability to collect money due is said to have forced the assignment.

Kansas City, Mo.—The electric lights in this city, which owing to some difficulty with the city officials have been shut down for some time, will be turned on again on August 28.

Bayonne, N. J.—The city council has passed an ordinance authorizing the Jersey City and Bergen Point Railroad Company to operate its road in the limits of Bayonne with electricity.

Norwalk, Ohio.—The stockholders of the Sandusky, Milan and Huron Electric Railroad have determined on the speedy completion of the road. In a few days the road will be in good running order to Norwalk.

Chester, Pa.—No fewer than five electric railway companies are now asking for privileges in this city. There are already twenty-eight miles of railway in the Chester system, with nine miles under construction to Darby.

Biddeford, Me.—It is understood that the York Light and Heat Company are negotiating with the Biddeford and Saco Railroad Company for a combine with a view to extending and operating the electric street railway.

Glyndon, Md.—The Baltimore Traction Company is to build an electric line to Glyndon. The road will be ten miles in length. It will be run from Pikesville to Reisterstown, and from there to Glyndon. A single track will be laid.

Tarentum, Pa. — A company of Allegheny men propose to build an electric road connecting Natrona and Parnassus. A bridge will be built over the Allegheny at Kensington, and a branch line will be run out to the fair grounds at Tarentum.

Nutley, N. J.—Preparations are making for lighting the town with electricity. Poles are being placed in position in the prominent thoroughfares, and by the first of October it is promised the township will be equipped with electric lights.

Youngstown, Ohio.—The Lanterman's Falls Improvement and Street Railway Company and the Youngstown and Canfield Street Railway Company have been consolidated, and the combination will be known by the name of the latter company, with a capital stock of $65,000.

Detroit, Mich.—It is said that the plans of the lighting commission for underground conduits are so arranged that whenever the city should decide to go into the business of supplying light to private consumers there will be no changes necessary in the ducts.

Salt Lake, Utah.—The Salt Lake and Ogden Gas and Electric Light Company have mortgaged the property and franchises of the company in Salt Lake and Weber Counties to the Farmers' Loan and Trust Company for $1,500,000, to secure the payment of 1,500 6 per cent. 25-year bonds of $1,000 each.

Mt. Vernon, N. Y.—The Union Electric Railway Company, of New York, has been granted a franchise to run to and through Williamsbridge, South Mt. Vernon, Mt. Vernon, Pelham and New Rochelle. It is the purpose of the company later to extend the road to Port Chester, taking in Larchmont, Harrison, Mamaroneck, Rye Beach, Milton Point and Rye.

Brooklyn, N. Y.—The Long Island Electric Construction and Equipment Company has been organized by Brooklyn men for electrical construction work in Brooklyn and on Long Island. W. J. Hayden is the general manager of the company.—The Franklin Avenue line of street railway has been converted into a trolley line, and the horse cars are no longer used on a portion of it.

Cincinnati.—About $5,000 damage was done by an accident at the Avondale Electric Railway power station, on Reading road, a few days ago. The accident was caused by a small piece of steel, not two inches long, slipping from its place, where it connected the governor of the engine with the cut-off. The speed of the machinery increased at a furious rate until finally everything literally flew to pieces and bits of broken wheels and shafts were hurled in all directions. Fortunately none of the workmen were hurt.

Toledo, O.—The new compound condensing engine added to the plant of the Toledo Electric Light Company is a mammoth piece of machinery, weighing about 95 tons. The fly-wheel, over which an 80-inch belt is driven, is 18 feet 4 inches in diameter, with an 82-inch face, and weighs 50,000 pounds. The steam is supplied by a battery of four Hammond vertical boilers, each tested to 150 pounds pressure. About 1,500 pounds of coal per hour is required by each boiler, but only two are necessary to furnish steam for the mammoth engine.

Philadelphia.—The new trolley road in Wissahickon and Manayunk is nearly completed and is expected to be ready to start early next month. The track is laid over the whole route and the greater part of the iron poles are in place. The new power-house at the Wissahickon depot is nearly finished and equipped with engines, dynamos, etc.—The Traction Company has applied to the Board of Highway Supervisors for permission to open all streets over which its Seventh and Ninth Streets and Market Street cable systems and its Union line extend, also Fifteenth street, from Mifflin to Jackson, for the purpose of trolley construction.

Syracuse, N. Y.—The Syracuse Consolidated Street Railway Company, which for three years has conducted all of the street railways of the city excepting the North and South Salina Street line and the main line of the People's Railroad, has virtually gone out of existence as all of the company's roads, franchises, rolling stock, and the property have been leased to the Syracuse Street Railroad Company for the term of the Consolidated Company's existence. The Syracuse Street Railroad Company is the company which was organized by the syndicate several months ago to operate all of the street railways of the city. Its capital stock is $4,000,000. The terms of the lease are the receipt by the stockholders of the Consolidated of an equal amount of stock in the Syracuse Street Railroad Company, and the assuming by the new company of nearly $200,000 of debt which the Consolidated Company owed at the time the syndicate secured control of that company.

Utica, N. Y.—Upon the solicitation of one of the chief promoters of the scheme to utilize the extensive water flow at Trenton Falls in generating electricity, A. Saunders Morris, chief engineer for the Westinghouse Electric and Manufacturing Company, visited the falls, and after a thorough inspection of the place reports the scheme practicable and a good one for Utica and near-by towns. Mr. Morris says: "In the dryest season I estimate that there will be 33,000 cubic feet of water per minute, which we can utilize. With a 20-foot head this will generate 5,000 horse-power. The loss through transmitting the power to Utica, a distance of 17 miles, will be about 20 per cent There would be sufficient for lighting the streets as well as furnishing power for the street car service and for factories. At Pomono, Cal., the power comes a distance of 14 miles, and also lights San Bernardino, 28 miles away."

Catalogues Received.

We are in receipt of a trade catalogue issued by the Westinghouse Electric and Manufacturing Company, devoted entirely to artistic reproductions of their standard electrical apparatus. The book contains forty-nine handsome half-tone illustrations, and is entirely artistic in style, the descriptions of the cuts and all matter of an advertising nature being omitted in this work. For those desiring further information on any of the apparatus illustrated separate pamphlets have been prepared which will be furnished on application.

The cuts include their various types of direct current dynamos for lighting and railway work, arc and incandescent machines, alternators, Tesla motors, electrical instruments, station appliances, incandescent lamps and other apparatus manufactured by the Westinghouse Company.

The "Electrical Engineering Company" of Minneapolis.

The Electrical Engineering and Supply Company, formerly of St. Paul, have removed their entire stock and business to Minneapolis, where they are located at No. 249 Second Avenue, South, occupying four floors and the basement of the Lincoln Block, which is being rapidly filled from top to bottom with the largest and best selected stock of electrical supplies in the Northwest.

Following are some of the specialties handled by this company in the Northwest:

National Incandescent Apparatus, Standard Arc Apparatus, Eddy Motors, Holtzer-Cabot Motors, Paranite Rubber Covered Wire, Grimshaw White Core, O. K. Weatherproof, Holmes, Booth & Hayden's Underwriters', Syracuse Sockets, Cutouts and Switches, and Packard Lamps.

Since moving to Minneapolis the company has, for convenience, shortened its name, and is now known as the "Electrical Engineering Company."

COMMERCIAL PARAGRAPHS.

The Electrical Engineering Company of Minneapolis report having just completed the installation of a 2,500 light alternator and transformer for the city of Brainerd, Minn., and are at present installing one 800 light incandescent machine, two 50 light standard arc machines, and two 40 light standard arc machines in the new department store being completed for S. E. Olson & Company, of Minneapolis.

Current from the incandescent machine will be furnished for running two passenger elevators, one freight elevator, and the cash railway system.

The Central Electric Heating Company, 26–28 Cortlandt street, New York City, have issued Catalogue No. 1, illustrating electric heating apparatus of every description for cooking and for domestic and industrial purposes generally, and for heating cars, buildings, steamships, etc., which is made under patents of the American Electric Heating Corporation.

Mr. J. Holt Gates, Western Manager of the Waddell-Entz Company, has recently moved his office into a suite of rooms on the eleventh floor of the new annex to the Monadnock Building, Chicago. For the benefit of his patrons and in order to more readily explain the merits of the Waddell-Entz dynamos he has installed a 3½ K. W. machine and connected it to the Edison mains.

The Abendroth & Root Manufacturing Company are sending out neat and handsomely printed descriptions of their standard boilers. The illustration showing Root boilers in process of construction at the Fair is particularly instructive and interesting.

Messrs. A. L. Ide & Son, the well known engine builders, of Springfield, Ill., have lately issued a set of new catalogues, illustrating their various types of Ide and Ideal engines, power transmitters, etc.

INCORPORATIONS.

The St. Charles Light and Fuel Company, St. Charles, Mo.—to deal in gas and electric light. Capital stock, $20,000. Promoters: John Dell, G. R. Blackford, Jos. F. Wash, St. Louis.

The Electric Company [incorporated in West Virginia], New York City—to acquire and dispose of patents and patent rights, and to construct tramroads, railways, etc., etc. Capital stock, $1,000,000. Promoters: Alfred Knisber and Edward Ayres, New York City; Samuel Sloan, Brooklyn, N. Y.

The Automatic Telephone and Electric Company, Jersey City, N. J.—to manufacture, construct, build, purchase, sell, lease, license, mortgage, loan upon and deal in and use electric machinery, etc. Capital stock, $250,000. Promoters: T. F. Goodrich, W. L. Trenholm, C. F. Cox, E. S. Wallace, New York City; C. H. Scrymser, Brooklyn, N. Y.

The Gray Electrical Transit Company has filed its certificate of incorporation with the County Clerk at Paterson, N. J. Its principal business will be carried on in Passaic and New York. The capital is $75,000, all paid in.

The Consolidated Machine Manufacturing Company, New York—to manufacture and sell electrical toys. Capital stock, $5,000. Directors: William R. Pope, Joseph Duff and Abraham Goldstone.

The Weaverville Electric Company, Weaverville, Cal.—to erect, equip and maintain electric plants, deal in and operate water rights, ditches, flumes and machinery. Capital stock, $10,000. Promoters: S. L. Blake, S. M. Gibson, T. E. Jones, C. W. Smith, J. W. Bartlett, all of Weaverville.

The Western Electric Heating Company of St. Paul, Minn. Capital stock, $1,000,000. Incorporators: Frederick P. Hager, Frederick P. Luther and Charles T. Johnston.

The Economy Novelty Manufacturing Company, Charleston, W. Va.—to manufacture, buy and sell electrical supplies, sell patents, etc., under patent of J. H. Lee Holcombe, No. 491,426. Capital stock, $100,000. Promoters: J. Duncan Harrison, Edw. G. Legg, Baltimore, Md.: J. H. Lee Holcombe, Washington, D. C.

The Wilcox Electric Company, Newark, N. J.—to buy and sell electrical patents, to manufacture and sell electrical railway appliances and to build and equip electrical railways. Capital stock, $150,000. Incorporators: Theo. B. Wilcox, Henry Wilcox, Ed. R. Dimick, T. P. Hoffman, of Newark; William Gibson, Charles E. Peet, Gouverneur M. Thompson, George J. Peet and William B. Smith, of New York; and J. W. Hinkley, of Poughkeepsie.

The Franklin Electric Street Railway Company, Franklin, Pa.—to construct and maintain an electric railway in Franklin. Capital stock, $24,000. Promoters: Alex. H. McKelvey, Jas. H. Donly, Geo. S. Davis, Warren, Pa.

The International Novelty Company, Newark, N. J.—to make and vend mechanical, chemical, electric, magnetic, scientific, artistic and other toys, puzzles, etc. Capital stock, $10,000. Promoters: Wm. S. May, Glen Ridge, N. J.; Eadley Hanley, Wm. H. Dean, New York City.

The Franklin and Oil City Electric Street Railway Company, Franklin, Pa.—to construct and maintain an electric railway in Venango County, Pa. Capital stock, $45,000. Promoters: J. H. Donly, A. H. McKelvey, Geo. S. Davis, Warren, Pa.

The Central Light and Power Company, Rochester, N.Y.—to produce electricity for light, heat and power. Capital stock, $25,000. Promoters: J. DeWitt Butts, Frank W. Elwood, Geo. Wilson, Rochester.

The National Street Railway Construction Company, New York City—to manufacture and sell all kinds of electrical and railway supplies. Capital stock, $5,000. Promoters: Edward S. Perot, Yonkers, N. Y.; Cornelius Gallagher, 218 E. 32d street, New York City; Jas. P. McQuaide, Plainfield, N. J.

The Citizens' Electric Light, Heat and Power Company, McDonald, Pa.—to supply light, heat and power by electricity in the borough of McDonald, Washington County, Pa. Capital stock, $12,000. Promoters: S. S. Johns, W. A. Jamison, R. M. McCastney, C. R. Buchheit, McDonald.

The Suburban Railway Company of West Chester, Pa., Philadelphia—to construct and maintain an electric street railway from West Chester. Capital stock, $400,000. Promoters: Wm. Jenks Fell, Wm. S. Kirk, Mahlon M. Childs.

The Portland and Hillsboro Railway Company, Portland, Ore.—to construct and operate electric light plants at Forest Grove and Hillsboro or elsewhere, and furnish electric light and power for public use. Capital stock, $1,500. Promoters: Theo. H. Liebe, F. J. A. Mayer, Frank Jobson, Portland.

The Queen City Electric Light Company, Denver, Col.—to furnish light, heat and power by means of electricity. Capital stock, $25,000. Promoters: Chas. E. Skillen, Frank J. Hango, Wm. Thorn, Denver.

The St. Louis and Kirkwood Electric Railway Company has applied for a decree of incorporation. The capital is $100,000, and the directors are Dr. John Pittman, George D. Edwards and George W. Taussig, of Kirkwood; Jeremiah Fruin, of St. Louis, and J. D. Housman, Sr., of Windsor Springs. It is the purpose of the company to operate an electric road from Forest Park to Meramec Highlands, two miles southwest of Kirkwood.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 18, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

501,488. Regulating Electric Locomotives. J. B. Blood, Lynn, Mass. Filed Nov. 16, 1892.
501,548. Trolley Wheel. E. M. Tousley, Jamestown, N. Y. Filed July 16, 1892.
501,676. Electric Railway Conduit. I. J. Cook, Newark, N. J. Filed April 23, 1892.
501,701. Electric Controlling and Locking Mechanism for Railway Switches and Signals. C. M. Wilder, Cincinnati, O. Filed Oct. 17, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

501,485. Incandescent Lamp Socket. H. P. Ball, Schenectady, N. Y. Filed Aug. 3, 1892.
501,491. Incandescent Electric Lamp. E. E. Cary, Boston, Mass. Filed April 6, 1893.

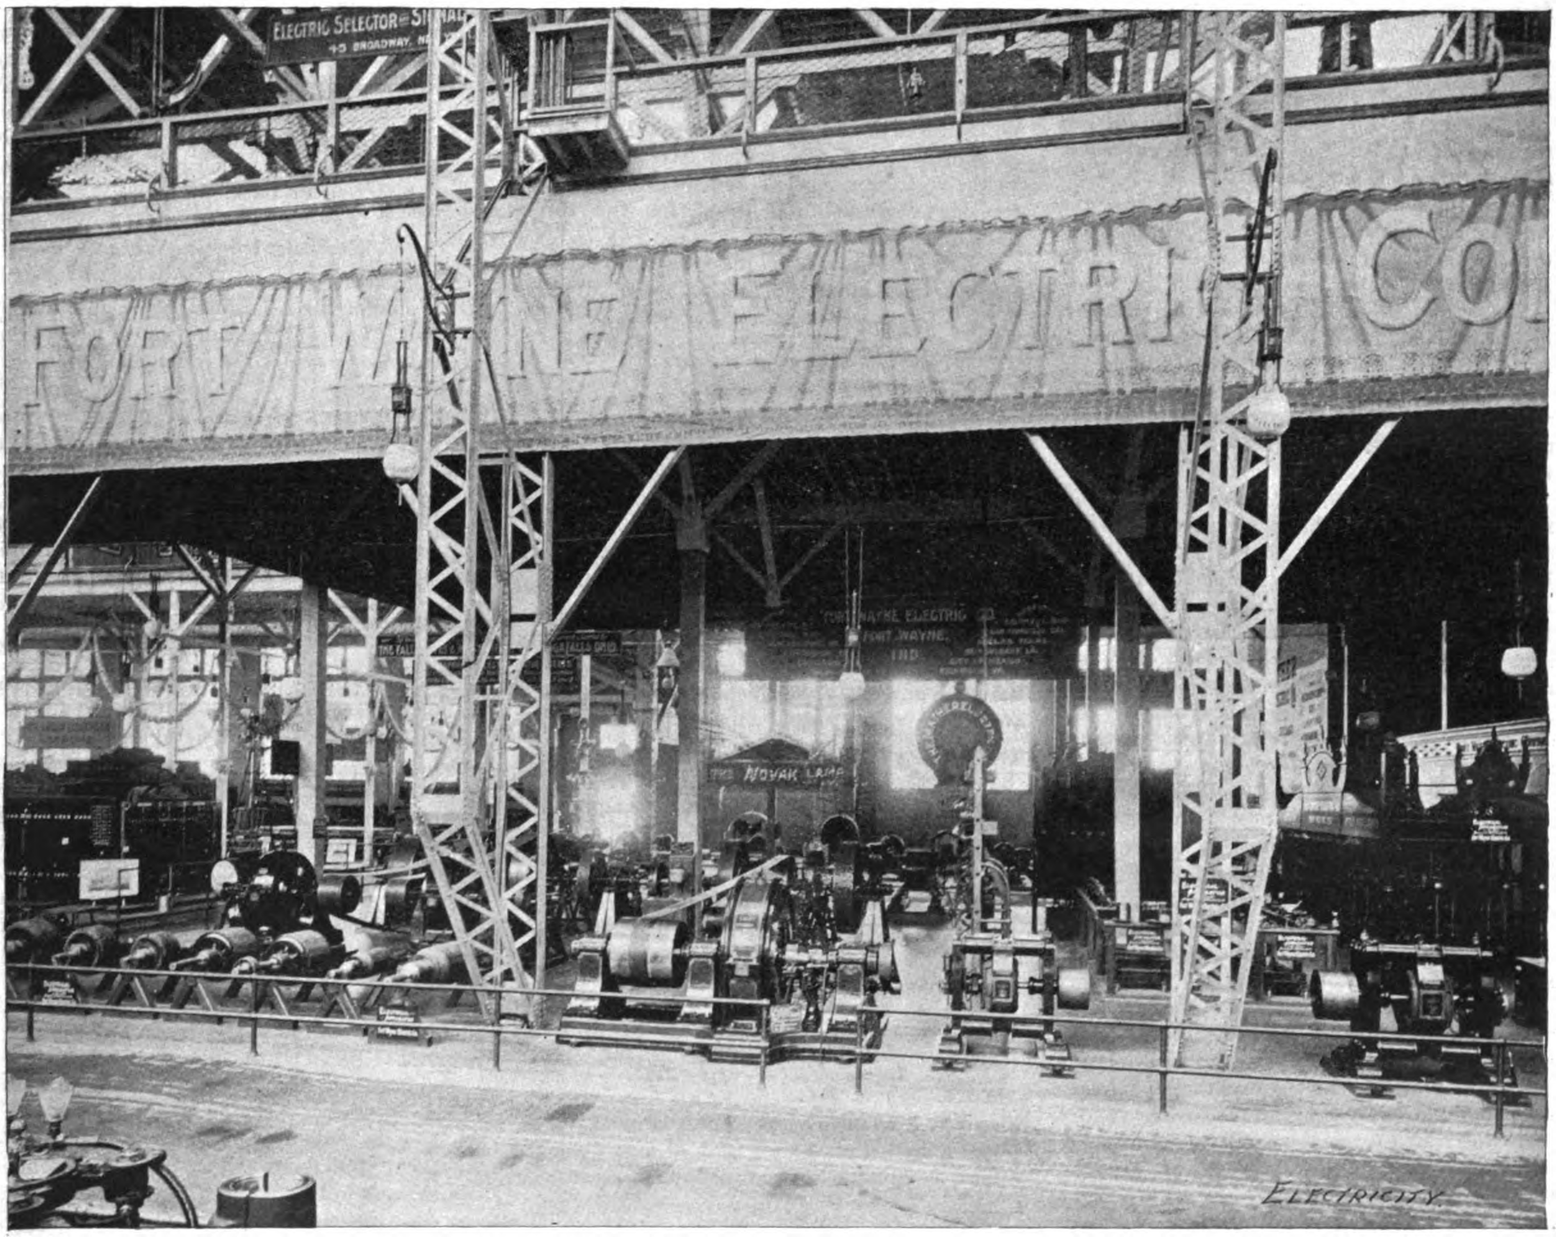
ELECTRICITY.

VOL. V. NEW YORK. AUGUST 23, 1893. CHICAGO. No. 6

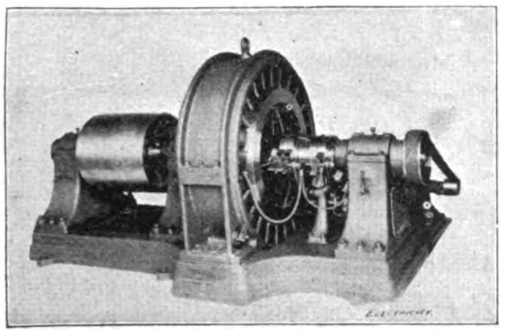


FORT WAYNE ELECTRIC COMPANY'S WORLD'S FAIR EXHIBIT (SEE PAGE 62.)

World's Fair Notes.

The Fort Wayne Company's Exhibit.

The exhibition of dynamos, motors and other electrical apparatus made by the Ft. Wayne Electric Company in the Electricity Building is certainly one of the most interesting displays, from the student's point of view, to be found in the Electrical department. The exhibit occupies a space near the middle of the west side of the building, on the main floor, and includes nearly all kinds of electrical apparatus built by the Ft. Wayne Company. A line of shafting and pulleys occupies the middle of the space. All the dynamos are belted directly from the pulleys, which can be thrown in and out of operation by the means of clutches. The line shafting is run by two motors belted to each end of the shaft. The motors are of the Wood type, one being of 90 horse-power at 220 volts pressure, and the other 125 horse-power and operating a 500 volt circuit.



THE WOOD IRON-CLAD ALTERNATOR. (FIG. 1.)

Besides these machines the company have the following dynamos in operation: Three Wood alternators, having a capacity respectively of 1,200, 1,500 and 3,000 lights each, three 2,000 C. P. arc light machines of 40, 60 and 80 lights capacity, and one dynamo rated at 120 arc lights capacity, using 1,200 C. P. lamps.

In connection with these machines all of the principal parts which make them complete are exhibited on tables arranged within the company's space.

A recent addition to these machines has just been placed in the exhibit, which consists of a new iron-clad alternator, shown in Fig. 1, to which a slow speed exciter is attached. This machine contains some novel points in its design which render it of interest. The parts are all made of comparatively small pieces to facilitate easy handling, and the shunts are placed in one pillow block where they are free from dirt and mechanical injury. There are two pairs of brushes, one of which can be removed or adjusted while the machine is running, and these are supported on an independent pedestal and shifted by means of a hand-wheel. The bearings are self-oiling and the armature is designed to permit good ventilation.

The current of air from the revolving armature is utilized to ventilate the crown of the machine, the pillow blocks and other parts.

The air is forced into the crown of the machine and out through channels connecting with the bearings, and in this way a constant circulation of air is kept up, causing the machine to run perfectly cool under any condition of load.

The wall which forms the north line of the company's exhibit has been tastefully decorated with incandescent lamps and a few telling signs which inform the visitor that the company's machines are used in the largest electric light station in the world. A number of Slattery meters are also mounted on the wall, and are connected up to the dynamos to measure the current used in the exhibit.

A very interesting part of the display is the rack of lamps, which shows 26 different styles of Wood arc lamps as manufactured by the Ft. Wayne Company.

Currents for and from the different machines are distributed by means of three switchboards, one for arc lights, one for direct current incandescent lamps, and the other for alternating currents. It is understood that one of these switchboards has already been sold and is to be shipped to the Philippine Islands.

Included in the exhibit are two very large search-lights, one of which is connected up and is shown in actual operation.

Besides this exhibit, the Ft. Wayne Company have a plant of 17 dynamos and generators in Machinery Hall which are used for lighting part of the grounds and buildings of the Exposition.

The company had the honor of having its machines selected by the Committee on Awards to furnish current for the tests of the electrical apparatus to be judged.

Geometrical Proof of the Three-Ammeter Method of Measuring Power.[*]

BY FREDERICK BEDELL AND ALBERT C. CREHORE.

The methods, now well known, for measuring power by three voltmeters or three ammeters, first shown by Professor Ayrton and Dr. Sumpner,[†] are applicable to the measurement of power of any circuit irrespective of the nature of the impressed electromotive force, and the general proof of the methods is given in the paper referred to. In the case of a harmonic electromotive force the methods are capable of simple geometrical proof. The writers have shown this [‡] for the voltmeter method, and in this note will give the corresponding proof for the three-ammeter method.

Let $R_2 L_2$, Fig. 1, be an inductive circuit whose power is to be measured, and R_1 a non-inductive resistance in parallel with it.

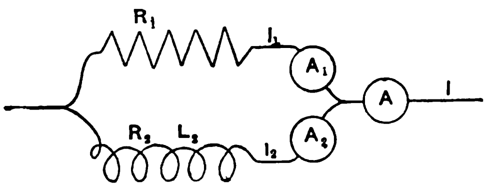


FIG. 1.

If the maximum values of the main and branch currents be denoted by I, I_1 and I_2, respectively, they may be represented as shown in Fig. 2. The current I_1 is in phase with the impressed electromotive force E; the main current, I, lags behind it by an angle θ; and the current I_2 lags behind it by an angle θ_2. The tangent of θ_2 is $\frac{L_2 \omega}{R_2}$; and the tangent of θ is $\frac{L' \omega}{R'}$, where R' and L' denote the equivalent resistance and self-induction of the parallel circuit,[‖] and ω is 2π times the frequency.

The power expended in the inductive circuit is $W_2 = \frac{1}{2} EI \cos \theta_2$. From the geometry of the figure

$$\cos \theta_2 = \frac{I^2 - I_1{}^2 - I_2{}^2}{2 I_1 I_2};$$

whence

$$W_2 = \frac{E}{4 I_1} (I^2 - I_1{}^2 - I_2{}^2),$$

where E, I, I_1 and I_2 represent maximum values. Writing virtual or square root of mean square values as obtained from ordinary measuring instruments, the expression for the power becomes:

$$W_2 = \frac{\bar{E}}{2 \bar{I}_1} (\bar{I}^2 - \bar{I}_1{}^2 - \bar{I}_2{}^2).$$

The power in the non-inductive branch is

$$W_1 = E I_1;$$

and the total power in the two branches is

$$W = \frac{\bar{E}}{2 \bar{I}_1} (\bar{I}^2 + \bar{I}_1{}^2 - \bar{I}_2{}^2).$$

The method is thus geometrically established for harmonic currents, which may be represented by lines in a vector diagram. For an alternating current, not harmonic, the proof does not hold unless we assume the current to be equivalent to a harmonic current, and the question then arises as to what will be the equivalent harmonic current. The equivalent harmonic current must be such that its square root of the mean square value and the expenditure of energy in the circuit are the same as in the case of the given current which was not harmonic.

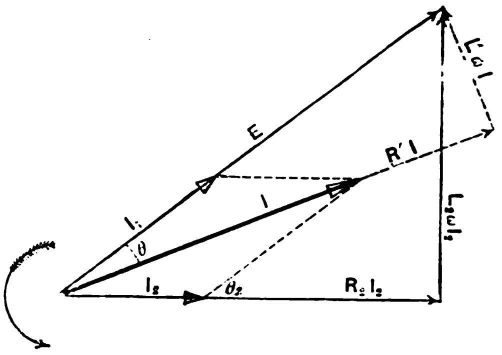

FIG. 2.

Melting Iron in Water.

Among recent electrical experiments made on either side of the Atlantic, that of melting a bar of iron immersed in cold water has perhaps excited more popular interest than any other.

The process is as follows: The apparatus used is a vessel of glass or porcelain, provided with a sheet lead electrode, connected to the positive pole of a continuous-current generator; the vessel contains sulphuric acid and water. A flexible cable from the negative pole is connected to a strong pair of pliers with insulated handles. Taking in the pliers a piece of metal of any kind, iron, for instance, and immersing it in the acidulated water, the liquid is seen immediately in ebullition near the iron rod or plate, which latter is rapidly heated and brought to a dazzling white in a few seconds, and soon begins to melt in spark-like drops. The heating is produced so quickly locally that neither the water nor the body of the metal rod have time to become hot.

So rapid an evolution of heat necessarily means a tremendously high temperature. In a very short time as high as 7,000 degrees Fahrenheit have been developed, which is proven by using a carbon rod instead of a metal one, when in a few moments amorphous carbon fragments are seen dropping off. The inventors claim to have attained with large currents the enormously high temperature of 14,000 degrees Fahrenheit, or nearly five times hotter than molten iron.

The first suggestion for the practical utilization of the discovery was for welding purposes, to which it is evidently particularly well adapted. Another application which the experiments would seem to lead toward is the tempering of one edge or one extremity only of steel-cutting tools. The hardening of the skin surface of large pieces of metal, such as armor plates, offers another inviting field. Krupp, it is stated, is already trying this new method of electric heating for tempering the superficial surface of large guns.

On the Carrying Capacity of Electric Cables, Submerged, Buried or Suspended in Air.

BY A. E. KENNELLY.*

The general laws that control the temperature elevation of electrically active wires, when buried or submerged, seem to have been fully ascertained, but the application of the theory to practical conditions has not perhaps been sufficiently developed. Professor George Forbes has, however, in his paper on the heating of conductors, read before the London Institution of Electrical Engineers in March, 1884, considered the cases of wires in air and water, as well as of wide horizontal plane strip conductors buried underground. It is here proposed to further develop the subject with the aid of a series of measurements made at the Edison laboratory on particular samples of Siemens cables, manufactured at the Schenectady Works of the General Electric Company. These measurements are described in Appendix I.

We may commence with the simplest case of a solid cylindrical conductor of radius r cms. carrying a steady current of C amperes with a resistivity at the working temperature of D ohms. The conductor is covered to radius R cms with a solid insulating material, closely fitting over which is a tube or cylindrical sheathing of lead or other metal. The electrical resistance of the conductor per centimetre of length is $P = \frac{\alpha}{\pi r_2}$ and the heat generated by the current in the same unit length is C^2P joules per second, corresponding to a thermal activity of C^2P watts.

If the surface of the cable's sheathing is kept at a constant temperature t degrees centigrade by the action of flowing water, it can be shown that in the copper conductor there will be no sensible difference of temperature between the centre and the surface for all cases that are likely to occur in practice. Similarly the difference of temperature between the interior and exterior surfaces of the leaded sheath will be negligible, so that finally, after the current has been kept steadily flowing through the conductor for what would be strictly an infinitely long time, but for practical purposes might be an hour, we may consider that while the sheath would retain throughout a uniform temperature t° C., the copper would have reached a steady temperature of $t + \theta$ throughout its substance, θ being the temperature elevation of the conductor due to the current it conveys.

This temperature elevation θ depends upon the thermal resistance offered by the insulator to the transfer of C^2P joules of heat energy across unit cable length of its substance per second. With infinitely great thermal conductivity or infinitely small thermal resistance, the insulator would transfer heat under an infinitely small temperature elevation ; and generally, if S is the thermal resistance of a body between two surfaces whose difference of temperature or thermal potential is θ° C. (referred, strictly speaking, to the centigrade scale of the air thermometer), the transfer of heat in the permanent state between those surfaces will be

$$H = \frac{\theta}{S} \quad . \quad . \quad . \quad (1)$$

heat units per second.

It is customary to express H in gramme-calories, i. e., water-gramme-degrees centigrade. but for the purpose here in view it is preferable to express the heat in terms of its equivalent mechanical energy, with the joule as unit.

The thermal resistance of a body depends upon its form and its thermal resistivity, in complete analogy with the corresponding electrical quantities. A homogeneous isotropic substance possesses therefore unit resistivity when a centimetre cube with 1° C. difference of temperature maintained between two opposite faces allows one joule of heat energy to pass between them, in the permanent state, each second. If δ denotes the thermal resistance of the insulator in the cable of radii r and R, the thermal resistance of the covering per centimetre of length of cable is

$$S = \frac{\delta}{2\pi} \log\varepsilon \frac{R}{r} \quad . \quad . \quad (2)$$

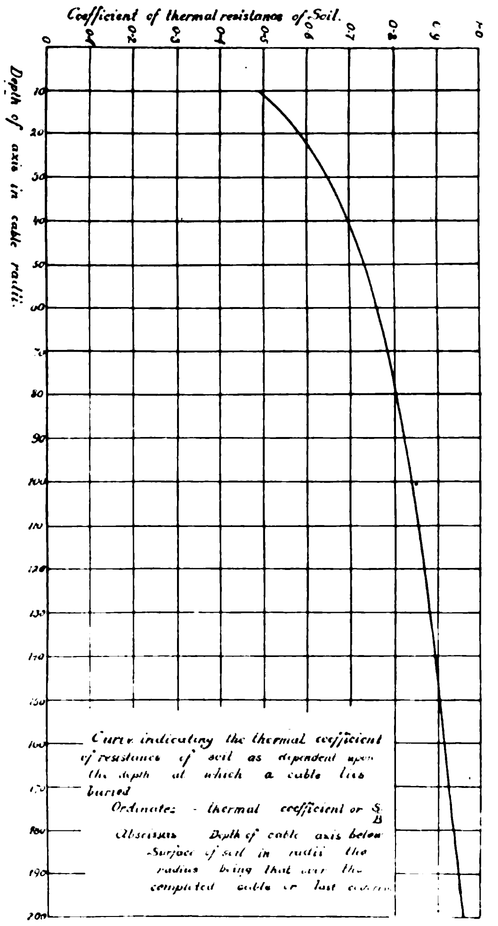
and by analogy with Ohm's law, the temperature elevation will be the product of this resistance and the energy current H or (C^2P) developed in each centimetre.

$$\text{Thus, } \theta = H\,S \quad . \quad . \quad (3)$$

$$\text{and } C = \sqrt{\frac{\theta}{P3}} \quad . \quad . \quad (4)$$

This relation (4) determines the limiting current strength for the cable when the radii and resistivity of the insulator are given and the temperature elevation has been decided upon.

The temperature elevation permissible in the conductor of a cable is generally limited by the attendant diminution of insulation resistance, or the softening of the insulating material. For Siemens cables, 60° C. may be taken as a fair limit in this respect, and since the normal temperature of air or soil may reach 35° C. in summer, the safe limit of temperature will be 25° C. or 46° Fahr.



With this value of θ in equation (4)

$$C = \frac{5}{\sqrt{P\,S}} \quad . \quad . \quad (5)$$

$$\text{or developing } C = 5\,r\sqrt{\frac{2\,\pi^2}{\alpha\,\delta\,\log\varepsilon\frac{R}{r}}} \quad . \quad (6)$$

A and δ being the electrical and thermal resistivities, P and S the electrical and thermal resistances per cm. of length, R and r the radii, and the conductor a solid cylinder.

This shows that if the thickness of the insulating cover maintained a constant ratio to the diameter of the conductor, the limiting current strength would be directly proportional to the radius, that is, to the square root of the cross-sectional area of the conductor. In that case, doubling the diameter of the wire would quadruple its cross section but only double the carrying capacity. It is evident, however, from an examination of the dimension tables for any kind of electrical cable, that the thickness of insulator does not usually increase in proportion to the diameter of the wire. and consequently the carrying capacity will generally increase faster than the radius and slower than the cross section. For the standard Siemens cables it appears that quadrupling the cross section of the conductor increases the carrying capacity about three times.

The resistivity of copper at 60 degs. C. may be taken as two michroms, and from the measurements of the samples of Siemens cables tested the mean thermal resistivity of the insulator was 750 units.

As an example, suppose a No. 4 B. & S. wire 0.2043″ (0.52 cm.) in diameter, covered with Siemens compound to a thickness of 0.1″ (0.254 cm.), lead sheathed, and submerged in water. Required the safe carrying capacity.

In equation (2) $\delta = 750$ $R = 0.514$ $r = 0.26$

$$\frac{R}{r} = 1.977 \quad \log\varepsilon\left(\frac{R}{r}\right) = 0.6816$$

$$\therefore S = \frac{750}{6.283} \times 0.6816 = 81.36$$

$$\text{Also, } P = \frac{0.000002}{3.1416 \times 0.26 \times 0.26} = 0.000009417$$

$$\therefore C = \frac{5}{\sqrt{81.36 \times 0.000009417}} = 180.7 \text{ amperes.}$$

STRANDED CONDUCTORS.

If the copper conductor consists of a strand of copper wires, equations (4) and (5) remain applicable, but (6) is no longer reliable. Taking (5), the resistance of the conductor per cm. can be determined in the ordinary way, and the thermal resistance of the insulator can be best found by taking its mean internal diameter for r in (2). The insulating cover surrounding and conforming to such a strand is no longer simply cylindrical, but the slight additional accuracy in determining the thermal resistance for the new interior outline would not repay the additional labor of computation.

BURIED CABLES.

The case of buried cables differs from that of cables submerged only in the fact that the external surface of the sheathing is not maintained at the normal temperature of the environment. The ground, in fact, interposes an additional thermal resistance to the flow of heat from the active conductor. Denoting this ground resistance by G, the fundamental equation (1) becomes

$$H = \frac{\theta}{S + G} \quad . \quad . \quad . \quad (7)$$

so that it is only necessary to increase the thermal resistance of the insulator by that of the soil to revert to the same method of treating the problem.

Assuming that the cable lies buried at a uniform depth below the level surface of the ground, the thermal resistance G of the soil will for a given external cable diameter depend only upon this depth and upon the thermal resistivity of the soil. We may consider that the temperature of the surface of the ground remains normal, and that, owing to the combined actions of radiation, convection and wind, the heat flowing upwards from the buried cable is entirely dispersed and dissipated at this surface. This is, of course, not strictly true, for the surface temperature of the ground immediately over the cable will rise appreciably when powerful currents are steadily carried beneath. It may be shown, however, that with the depths at which cables are usually buried, the assumption involves an error that is practically small, while it renders amenable to simple numerical treatment a condition that would otherwise be too complex to ordinarily compute.

---

* Read before the Association of Edison Illuminating Companies.

If, for example, a cable buried at a depth of one metre were of such dimensions as to carry safely a steady current of 750 amperes, the final elevation of temperature at the surface of the ground over it would be less than 20° C., even ignoring the great reducing influence of wind, and the ground surface, which by assumption should remain at normal, could nowhere exceed the normal by two degrees centigrade, a discrepancy whose consequence upon the carrying capacity of the cable would be negligible, and whose tendency would be to slightly underestimate the temperature elevation of the conductor.

On this assumption, then, the surfaces of heat flow are cylindrical, and the isothermal surfaces are also cylinders eccentric to the conductor. The thermal resistance

$$G = \frac{g}{2\pi} \log \varepsilon \left(n + \sqrt{n^2 - 1} \right) \quad . \qquad (8)$$

where g is the thermal resistivity of the soil, and n is the ratio of the depth of the cable's axis to the cable's radius, or in other words, the depth of the centre of the cable in external radii. From this formula the following table and the curve in Fig. 1 are obtained.

n	Coefficient of g	n	Coefficient of g	n	Coefficient of g	n	Coefficient of g
10	0.4760	60	0.7620	110	0.8584	160	0.9181
20	0.5871	70	0.7865	120	0.8730	170	0.9277
30	0.6516	80	0.8077	130	0.8850	180	0.9368
40	0.6975	90	0.8265	140	0.8968	190	0.9454
50	0.7330	100	0.8433	150	0.9078	200	0.9536

From these curves it appears that at depths of fifty radii a quadruple increase—to 200 radii—only changes the resistance per centimetre of length from 0.7339 to 0.9549, an increase of about 30 per cent.

(To be continued.)

Electricity in Artillery Practice.

The Eddy Electric Manufacturing Company of Windsor, Conn., have perfected an electric motor attachment for the control of Gatling guns which is a conspicuous step forward over previous efforts in this direction, and is regarded by the Ordinance Department as very near to perfection.

The motor does not protrude at the side of the gun base, but is, when attached, a part of the gun, being afforded the same protection as the mechanism of the gun itself.

It occupies a space of fifteen inches in length, with a diameter the same as that of the gun, being of 1 H. P. capacity. A maximum of 2,000 shots per minute can be attained.

Electricity in Gardening.

By the use of electric light the Hon. W. W. Rawson, of Arlington, Mass., claims he makes a gain of five days in each of his three crops of lettuce; that is, two weeks in a season. That the gain on one crop pays all the expense of the electric lighting for the season, thus giving him the gain on the other two for extra profit. His attention was first called to the usefulness of the light by the advance made in the growth at the ends of his greenhouses next the street and in the glare of the electric light. This was so marked that he introduced the light through his lettuce and cucumber houses. Dr. Bailey, of Cornell University, says, as the result of his own experiments, that the influence of the light is greatly modified by the interposition of a glass roof. Plants injured by a naked light were benefited by the protected light. Five hours' light per night at a distance of twelve feet hastened maturity a week or ten days, but proved injurious to young plants and those newly transplanted.

Carbon and its Uses in Electrical Engineering.*

BY CLARENCE M. BARBER, C. E.

In the year 1810, Sir Humphry Davy connected the poles of a battery of 2,000 elements by two charcoal points, and produced one of the most brilliant artificial lights that had doubtless ever been seen.

So little value was attached to this experiment that it was merely entered in the note book of the great physicist, and remained there apparently unnoticed until 12 years later, when it appeared as a communication to the Royal Society. Scarcely do we find a more striking example of the great advancement in electrical science than when we note that this bright spark has grown in strength and beauty, until now there are required to feed its ever-spreading rays 200,000,000 of carbon pencils for the present year in the United States alone.

In electrical engineering, the term carbon is used to designate an artificial solid, which, through mechanical or chemical means, is derived from some of the natural forms of carbon. It is moulded under great pressure into cylindrical pencils for arc lighting, or into rectangular blocks or plates for battery or other uses. It is not the purpose of this paper to describe minutely the process of making carbon, nor is it necessary, as there are published descriptions which cover the ground fairly well. However, an outline of the general principles may not be out of place.

The materials usually employed are coke and pitch. The coke should be as free from solid impurities as is obtainable. Petroleum coke is largely used, although other varieties are often sufficiently pure for the purpose. It is ground to powder, and the volatile components are driven off by heating in retorts. Melted coal tar pitch is then thoroughly mixed with it, and for some kinds of carbon lampblack is also added. The mixture is then cooled, again ground to powder, and is then ready to be moulded or forced.

The process of moulding consists of filling the material into steel moulds, which are made in two equal parts, so arranged that the lower half of the mould will contain a sufficient quantity of the material for the entire charge. The upper half is then placed in position upon its counterpart, the mould is placed in a furnace and heated sufficiently to soften the fusible ingredients. It is then put under a pressure of about 400 tons, after which the 16 pencils, or carbons as they are called, are removed from the mould. After cooling they are ready for the next process, which consists in handling the carbons one by one, examining and trimming of the webs which usually occur between the individual pencils as they lie in the mould; they are then packed in furnaces holding from 30,000 to 50,000, where they are baked at a high temperature for about 100 hours. After cooling for a like period they are sorted for straightness. A portion are then sent to the consumer, but a large portion are first coated with copper.

The process of forcing is proximately the same as that of moulding until the material is ready for the moulds; then, instead of being moulded, it is heated and made into cylindrical plugs, which are placed in a heavy iron cylinder, and, by means of a plunger driven by hydraulic pressure, the plastic material is forced through a steel-bushed orifice and comes out in the shape of a continuous cylinder, which is cut to the lengths desired. The carbons are then sent to the furnaces, and from this point the process is the same as for the moulded.

The forcing process permits of a wide range of shapes, as by changing the size of the steel-bushed orifice, cylindrical carbons can be forced having a diameter of 1-16 in., and from this size up to or even above 4 ins in diameter. Many other shapes besides cylindrical can also be made, such as plates that are not much over 4 ins. wide and of a thickness of from ⅛ to 1½ ins. or over. These are cut into short lengths and used for dynamo or motor brushes. Plates as small as ¼ x ⅛ in. are also forced for small generator or motor brushes.

There is a great difference in density and structure between moulded and forced carbon. The pressure under which moulded carbon is made is about 8,300 lbs. per square inch, while by the forcing process the pressure required is double or three times as great. By the method of forcing, the material is crowded together as it is pressed toward the small end of a conical chamber and is finally forced out at the vertex, thus giving a combination of lateral and end pressure.

By the method of moulding, the carbons receive side pressure only. Under the side pressure, the material tends to laminate in planes parallel to the axis of the carbon; while under end pressure, the planes of lamination are at right angles to the axis. As usually made, the pressure is not sufficient to produce distinct lamination; but it is evident that the structure of the material is inclined toward this class of formation, as in the case of slate rock which is laminated in planes at right angles to the lines of pressure. Under certain conditions, lamination may be observed both in moulded and forced carbon.

Carbons, as they are usually made for arc lamps, are about 7-16, ½ or ⅝ in. in diameter, by about 12 ins. in length. In some cases pairs are used, a carbon 7 ins. and one 12 ins. usually constituting a pair. Besides those there are several other sizes in use; for searchlights and for many of the large lighthouses, carbons as large as 1½ ins. in diameter, and often larger, are employed.

In addition to the ordinary pencils, many other forms may be moulded, such as cups or crucibles, or almost any design where the material can be retained in moulds and submitted to great pressure. Plates are made 12 to 14 ins. square, and in thickness from 1-32 in. to over 1 in.; and even larger sizes are often made.

In its physical properties carbon varies greatly, the variation depending upon its composition and treatment in the process of manufacture. The hardness may be from that of chalk to that of crockery, and its specific gravity may vary to about the same extent. It is quite brittle, and this property is retained through all its stages of hardness. The tensile strength and resistance to crushing increase with the hardness.

For cutting carbon the emery wheel is generally employed; it can be drilled or cut in the lathe with steel tools, but its effect is to wear them away very rapidly; even diamonds can be used as cutting tools but a short time. On the hardest specimens these operations are performed with difficulty even with the best of tools.

As applied to electrical engineering, the most important and interesting use of carbon is in the arc lamp; here we find phenomena that are wonderful even in the light of the most advanced science. If two ½-in. carbon pencils be placed with their points in contact, and are included in electric circuit having a current of 10 amperes, a slight amount of heat will be developed in the body of the pencils, which will be greatest at the point of contact; if, while the current is still passing, the pencils be separated a few millimeters, an arc of great luminosity and heat will be formed. If the poles of a voltmeter be connected with the pencils, the voltage due to the resistance of the arc will be seen to vary directly as its length, or nearly so; at about 20 volts the arc will be scarcely visible, and will increase in brilliancy and heat as the points are separated until the voltage reaches about 50, when the light will appear to be the most brilliant. At a point somewhere above this voltage, possibly 70 or higher, the arc will go out with a snap.

---

* Read before the International Engineering Congress of the Columbian Exposition, 1893.

In the above case, if the current be maintained constant, of course the watts required will vary as the voltage, and this variation of the total watts is employed by all makers of arc lamps as a means of moving the feeding mechanism. This, in some lamps, may be so delicately adjusted as to move the carbons toward each other when the distance between the points has increased an amount corresponding to 1 volt, while many lamps require an increment of 5 volts to cause the teeding device to respond.

One of the most notable points in regard to the burning of the carbon arc is that the temperature in the positive carbon rises much higher than in the negative. It is noticed that when we extinguish the arc by turning off the current, the point of the positive carbon remains incandescent after the negative point has become black; the intensely heated crater formed on the positive carbon radiates far more light than the incandescent point which is formed at the end of the negative. The consumption of the positive is about twice as great as that of the negative when burned in the air; if burned in a vacuum, then the positive only is consumed. These facts seem to indicate that the larger part of the energy of the current is expended upon the positive carbon. A large part of the energy expended upon the arc is doubtless used in maintaining a counter electromotive force, and another portion is absorbed in the conversion of solid carbon into vapor.

The arc may be colored by the introduction into the carbon of almost any foreign substance, and the color is characteristic of the substance employed, as in the case of the Bunsen flame; and as there are but few substances which are not volatile in the electric arc, the range of color is very large. The intensity of temperature is, without question, highest in the centre or inner portion of the flame and lowest toward the outer circumference; for this reason the vapors of substances arrange themselves in concentric envelopes—those which volatilize at the highest temperature taking positions nearest the centre, those which volatilize at the lowest temperature becoming the outer envelope.

The carbon flame affords one of the best subjects for spectrum analysis; it is therefore of great value for this purpose, and by its use the field of the spectroscope has been greatly enlarged.

It is perhaps important to note that, aside from the color effect of foreign substances in the carbon pencil, there is in most cases a reduction of the light and generally a lengthening of the arc; this may be accounted for on the supposition that foreign substances usually volatilize at temperatures lower than carbon and hence supply vapors which radiate less light, and, volatilizing more rapidly, the quantity of the vapor is increased and a corresponding reduction of voltage may also be noted. If the foreign substances are not homogeneously incorporated with the carbon, the arc will be unsteady and the light will be unsatisfactory.

In the burning of arc-lamp carbons, there is always a quantity of carbon dust that falls from the burning points; this is not a product of combustion, but particles of carbon, which are detached and thrown off from the highly heated points by calcination. Many attempts have been made by inventors to reduce or prevent the loss of life of carbons due to this cause. Some degree of success has been attained by introducing into the carbon ingredients in the shape of substances which, fusing at a comparatively high temperature, become slag and mix with the detached particles and prevent them from falling off; and retaining them until they are consumed, the life of the carbon is prolonged to a very marked degree.

The hissing sound so frequently observed in the arc-light carbons is a matter of importance. There seems to be a strong current of air and vapor moving between the highly heated points; when this current impinges in a certain manner against the point toward which it flows, hissing will be the result. To illustrate: if a jet of air be blown from a small tube, at high velocity, against a solid substance, a hissing sound will or will not be produced, depending upon the velocity of the air, the nearness of the solid and its configuration.

Many experimenters have endeavored to obtain a quiet, steady arc by the introduction into the carbon of foreign matter, which, by producing vapor more easily than carbon, will so modify the conditions as to prevent hissing; and, with a view of holding the arc in the centre, a core is used. This core is simply a centre, which may be 1-16 inch or more in diameter, of a material that is different from the body of the pencil and contains more or less of the foreign matter.

Some of the most quiet and steady-burning carbons that are in use have been obtained by the use of foreign matter and a core. Carbons are also made with hollow centres, through which solutions of salts are simply poured, a sufficient quantity being left therein to produce the desired result.

As early as 1867 M. Carré coated carbons with metals, such as zinc and tin; and about the same time Mr. Joseph Van Malderon experimented with carbons electroplated with copper. Carbons have, therefore, been electroplated almost from their first introduction, and copper has been the metal used. The only reason the writer has seen assigned for this use of copper is that it reduces the resistance, conveying the current to the end of the pencil with but little loss of energy. The life of the carbon is increased by coating with copper from 8 to 10 per cent.

The total resistance of an uncoated pair of ½-inch carbons, in a newly trimmed lamp, is about .20 ohm, while the total resistance of the lighted lamp is about 5 ohms. It is evident, therefore, that the resistance of the carbons is about 4 per cent. of the total resistance of the lighted lamp. The resistance of the lamp coils may be 2 per cent. The decrease of resistance due to copper coating will not account for the increase of the life; this is due, in the writer's opinion, to the fact that the copper tends to support and retain the particles of carbon that are detached from the points by calcination; to some extent, also, the fused copper forms in liquid beads, and, by absorbing the calcined carbon dust, tends to prevent its loss.

A comparatively new use for carbon is found in the carbon brush for dynamos and motors; here carbon is substituted for the copper brush, and hence retains the name, which appears like a misnomer. Carbon brushes reduce the cutting of the commutator and the sparking to almost nothing. The same commutator may be used for years with carbon brushes which, if copper were used, would be worn out in a few months. The quality of the carbon brush is of great importance; it must be of fine texture, sufficiently hard, and should act in some degree as a dry lubricant, and it should not give a squeaking noise. These are points that can be provided for by the manufacturer. Much difficulty is sometimes experienced by heating. This, of course, is a question of conductivity, and can usually be remedied by making the brush larger, or by coating it with copper, or by doing both.

The telephone is indebted for a large measure of its great success to artificial carbon. Here its value depends upon the principle that an increase of pressure produces a decrease of resistance. The writer is inclined to think, with Mr. S. P. Thompson and others, that the increase of pressure simply makes a more perfect contact. As the resistance of carbon is higher than that of metals, it is, in some cases, an excellent material for this purpose, and especially where moderate resistance is required

Among the advantages of carbon for electrical resistances, we may note the fact that it can be heated almost to a red heat and held at this temperature, without undergoing any change whatever, and being practically infusible it will stand for a short time very high temperatures, even in the atmosphere, without suffering any deterioration. If held long at a red heat, however, in the air, it will calcine and sometimes oxidize. Carbon has also the remarkable property of showing a reduction of resistance as the temperature rises. At high temperature this is very marked; for example: the decrease in resistance of an incandescent lamp filament at a white heat may be one-third of its resistance when cold. At temperatures below a red heat, however, the change of resistance is of comparatively little importance.

Some of the difficulties that attend its use as a resistance material are as follows: the resistance of carbon varies between wide limits; two carbon pencils ½ inch in diameter and 9 inches in length could be selected, of which one would have a resistance of .20 ohm and the other .07 ohm. The forced carbon being more dense is always lower in resistance than the moulded, other conditions being the same. The resistance, however, may be largely controlled by variations in the manufacture.

The connection between carbon and a metal conductor often becomes a troublesome point, especially if high temperatures are to be used. For low temperatures the carbon may be electroplated with copper and the metal conductor may then be soldered; but for high temperatures the connection must be made by some form of clamping device.

Carbon is not used as a resistance where calibrated resistances are required, owing to the difficulty of predetermining its exact resistance. For resistance purposes, carbon is used in the form of pencils as small as ⅛ inch in diameter; larger sizes are also used; it has also been used in the granular form and as a powder.

As a contact piece, where contacts must be made and broken frequently, carbon has a great advantage in many places over metals; and frequently, where metals are used in switches for contacts for large currents, carbon blocks are successfully used as a last point of contact. In such places as these last mentioned, carbon often gives a long arc, but even where one pole is metal, instead of burning the metal the current seems to expend its energy on the carbon, which suffers but little and is renewable.

Carbon is almost universally used in primary open-circuit batteries for the positive pole, and for this purpose it is made in the form of cylinders or plates. It is not acted upon at ordinary temperatures by any acid or other liquid known to chemistry, and in batteries it is easily depolarized. Carbon is also used, to a limited extent, for crucibles; and, when mixed with clay, stands very high heats without oxidation.

It is remarkable that while carbon is made in a variety of forms its uses are almost entirely confined to electrical engineering; and as we note the rapid advancement of this new department of scientific work, we may also note, as one of the changes it has brought to our century, this new industry—the manufacture of carbon.

A slight idea of its growing magnitude in the United States may be gained from the fact that it claims an investment of over $1,500,000.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 75, 520 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:
UNITED STATES, - - - - - $2.50
IN CLUBS OF FIVE OR MORE, - - - - $2.00
FOREIGN COUNTRIES, - - - - - - $4.50
SINGLE COPIES, - - - - - - $ .10

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.
Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

International Electrical Congress.

Before this issue of ELECTRICITY is in the hands of its readers the International Electrical Congress will have commenced its sessions in Chicago. This congress will undoubtedly constitute the most important assemblage of electricians which has ever taken place in the history of the science, and the representative character of its members and its wide international scope render it an occurrence which is unlikely to be repeated for many years to come.

The general congress is divided into three sections which will each consider special phases of electrical work. The first section will take up questions involving pure theory, such as electric waves, conduction, magnetism, etc.; the second section is on theory and practice and will constitute the most interesting part of the proceedings to the general electrical engineer. The third section will be devoted to pure practice, including telephony, telegraphy, traction, etc.

In addition to these sections there is also to be a smaller body known as the Chamber of Delegates, composed of representative delegates from different Governments, whose work will consist in considering the proposed new electrical units and their values, with a view to having the same legalized by the Governments represented.

The subjects to be considered by the Chamber of Delegates relate principally to electrical nomenclature and standard values of units, and on these subjects considerable variance of opinion exists among the representatives of different Governments which will probably call forth extended discussion. For example, the "henry," which has been generally accepted by American and English electricians, is objected to by French authorities, this same unit having been styled a "quadrant" at the last electrical congress in Paris. The reciprocal of the ohm for which "mho" has been suggested, and several other units which have been found desirable are likely to be the subjects of considerable discussion by this body.

The business of the three sections of the general congress will include the reading and discussion of some thirty papers by a number of the most eminent men in the electrical profession. During the sessions, which take place from August 21 to 25 inclusive, public lectures by prominent members, including one by Mr. Tesla, will be delivered.

The discussions of the papers read, which will cover a large range of highly important topics, promise to be of unusual interest, and arrangements have been made by which readers of ELECTRICITY will be furnished with prompt and complete reports of these important proceedings.

……o……

ELECTRICITY has no apologies to offer for its twelve-month attack on the sham Electric Trust, nor its results. If the latter had been different, there would now be scores of independent manufacturers and dealers on the verge of bankruptcy, instead of the General Electric Company. We have made our fight for a principle—free competition and honest competitive methods—and we have won. The events of the hour are ample confirmation of our most serious accusations.

The Uses of Carbon.

A suggestive paper, by Mr. Barber, on the uses of carbon in electrical engineering, will be found elsewhere. The extent to which this element has found application in electrical work and the peculiar properties possessed by it, which are found in no other material, make it of special interest to the electrician, by whom the manufacture of carbon has been called into existence.

Electric lighting, both arc and incandescent, is dependent upon the use of carbon almost absolutely, and in this field it stands without a rival or substitute. Both of these methods of illumination have given rise to large industries in the manufacture of carbon, and no commercial form of electric lighting without carbon has been discovered.

The telephone is perhaps the next most important electrical device demanding the use of carbon. The microphone, which is the fundamental component of the telephone, depends upon a property of carbon which is peculiar to this material alone. The principle of the microphone, discovered by Hughes in the early history of applied electricity, is the subject of some dispute as to whether the variations in the resistance of the circuit are due simply to the change of contact with the carbon with pressure, or whether this pressure varies the resistance of the whole mass of carbon. As this phenomenon is only noticeable with carbon, however, the latter assumption has been generally credited.

In electric primary batteries carbon has been found invaluable, and the carbon-zinc couple are now far more generally used than any other element. In this capacity carbon has replaced much more expensive materials, and in general is better adapted to use in batteries than any other of its substitutes, on account of the property, which it alone possesses, of resisting any chemical action in all kinds of battery solutions.

Most dynamo machines, except those of low voltage, are now supplied with carbon brushes, which have increased the life of commutators many times above what was possible with copper brushes. In all cases where sparking occurs at carbon and metal contacts the metal is comparatively untouched and the carbon wears away evenly leaving the contact surfaces smooth. For this reason its use in switches and other pieces of apparatus containing sliding contacts is found of special advantage. Its use as a resistant, although of value in some cases, is not general owing to its great variation in conductivity under different conditions. The facility with which manufactured carbon may be turned out with any desired degree of density or hardness also adds greatly to its value in electrical appliances.

Considering the manifold uses to which manufactured carbons have been applied in electrical work, this material may fairly rank as one of the most useful to the electrical engineer and one upon which the great industry of electric lighting depends absolutely.

……o……

THERE is every probability, as we go to press, that sensational developments in General Electric will be announced before the end of the month.

There is no doubt that Thomas A. Edison will be again an active factor in an electrical enterprise before January 1, 1894. It would not be strange if Mr. Edison should make his new venture exclusively in the manufacture of incandescent lamps. He is fully prepared.

……o……

THE TRUTH IS COMING OUT. There are three theories by which we can account for the emphatic statements concerning General Electric published in a Boston paper and reprinted elsewhere in Electricity.

The first is that the editor has just escaped from a lunatic asylum.

Second, that he questioned his ability to earn a livelihood during a long period of financial depression and endeavored to make a sure thing of breaking into jail.

And third, that the outbreak was instigated by some one who has tried to divert public attention from his own deceptive tactics by throwing mud at those who have found him out; that the writer obtained information from a high official in the General Electric Co., and that he has a guarantee against any serious prosecution; that the matter was, in fact, inspired by a man who has been thoroughly beaten at a game in which he considered himself an expert, but in which he was only an unprincipled novice, and who has so far lost his head as to believe that he can by such methods place all the odium for the wholesale slaughter of the innocents in General Electric upon those who have found him out, and who will yet expose him to the public.

Electricity subscribes to the latter theory.

We are aware that there are some statements in the article which are inconsistent with this view of the case, but the gentleman referred to is a New Englander, and no doubt a disciple of Emerson, who believed that "consistency is the hobgoblin of weak minds."

The annual report, which is characterized as "false from beginning to end," was prepared by Mr. Joseph P. Ord, a Drexel & Morgan protege, sure enough; but it was signed and presented by the president of the company, Mr. C. A. Coffin, himself.

No newspaper man, however venal, as well-informed as the *Telegram* man seems to be, would make such misstatements as appear in regard to the affairs of the Edison General Company unless he had been deceived by a man in whom he had confidence or *in whose service he was working.*

The directors and bankers of the Edison General Company knew it to be bankrupt, and they made no secret of the fact.

But the Edison General Company was in infinitely better condition than the Thomson-Houston Company, except for ready cash. It had ten times more *bona fide* assets than the Thomson-Houston Company, assets which have not vanished, and which have proved salable. The Edison assets were not, like the Thomson-Houston assets, largely made up of stocks of paper companies or manufacturing companies which were all losing money. There was no fraud upon the part of the Edison people.

There was misrepresentation on the other side, systematic misrepresentation, juggling with figures, and base deception.

The system of bookkeeping adopted by the Edison Company was the best known in the commercial world; only one set of books was kept for both the officers of the company and the public, and deception was a practical impossibility upon those who had access to the books.

This was not the case with the Thomson-Houston Company.

That Mr. Pierpont Morgan has put Mr. C. A. Coffin to sleep, there is little doubt. But the actual facts of history cannot be perverted in this manner for whatever motive.

More than one of the New York directors were grossly deceived, among them Mr. D. O. Mills and Mr. Pierpont Morgan. That they decided some weeks ago to teach Mr. Coffin a lesson in the art of financiering is beyond question. They were hypnotized for a season, but the spell wore off.

Mr. Coffin's high reputation when he entered the electrical business carried him through for ten years in New England, but served his purpose for a brief year only in New York.

Electricity has no sympathy for any member of the General Electric's Board of Directors, and nothing but condemnation for their conduct. That men like Twombly, Mills and Morgan should allow their names to be used in connection with a concern of whose affairs they were ignorant, is scarcely less culpable than the studied deception of the man who engineered the scheme to humbug the public.

We shall expect the *Telegram* to produce the facts, if it has any. Few will be found to believe its unsupported assertions.

Secrecy in the affairs of any company like General Electric is unpardonable, and when such secrecy is studiously maintained in the face of a situation like the present, the public is justified in believing that something is wrong. The extent of that something is a matter of opinion.

The whole truth is coming out soon, and Mr. Coffin's New England friends, who have stood by him with a loyalty far more credit able to their hearts than to their intellects, will yet be compelled to admit their error.

Violent outbreaks like the one referred to may be wholesome in effect by hastening an investigation of the company's affairs by disinterested parties.

The collapse of the company, which may be announced at any moment, will be a serious blow to the trade, but it is inevitable and necessary. The benefit, however, will overbalance the injury if the lessons taught are heeded by those who will come into the management of the enterprise.

……o……

The interests of the *Street Railway Gazette*, it is announced, will hereafter receive the undivided attention of Mr. C. E. Stump, who needs no introduction here. Mr. J. W. Dickerson is also added to the editorial staff. Great things will now be expected of the *Gazette*, and Electricity believes there will be no disappointment.

His name is Charles Ausgespielt Coffin; and we could pity him if we could forget that it was he who said: "*We are going to do this business, and you may as well fold your tents and get out.*"

……o……

A leading banking house of Philadelphia was semi-officially advised last week that a receivership for the General Electric Company was inevitable unless the plan to provide for the floating debt was speedily consummated; and moreover, that the probability of the plan's success was doubtful, which seems now to be confirmed by the many changes made in the plan.

……o……

Electricity does not believe the plan will be successful, for obvious reasons. If the bondholders of the company are not extremely complacent people they will not allow the assets to leave the treasury in any manner yet proposed; and if the merchandise creditors are not even more complacent, they will have something to say before the collection of their accounts within a reasonable length of time is rendered impossible by legal complications.

……o……

The recent troubles between France and England over the former's possessions in Siam have brought out the fact, which is viewed with considerable uneasiness by the French, that England controls nearly all the sub-marine cables of the globe. During the Siam flurry telegrams addressed to the French Government were sent to the British Foreign Office three or four hours in advance. Of twenty-eight cable companies two are French, one Danish, three North American and three South American. These companies have, all told, 125,000 miles of cable, three-fourths of which are under English control.

……o……

We would like to know what the *Electrical Engineer* means in ascribing to London *Punch* certain comments of the London *Electrician* on a note on "Calculating Boys," etc., which appeared in the *Engineer* some weeks ago.

"The Book of the Fair."

It is fortunate that so able an historian as Mr. Hubert Howe Bancroft should take up the labor of preparing a complete history of the World's Fair. The work is to be published in twenty-five parts of about forty pages each, folio size, by the Bancroft Company of Chicago and San Francisco.

The literary world has been amazed at Mr. Bancroft's capacity for work. He has barely concluded a series of twenty-five or thirty volumes of Western history, a work which has few blemishes, and which has stamped its author as a marvel of industry and ability.

Mr. Bancroft's work is the more remarkable from the fact that he was well along in years before he undertook any literary work. He was a bookseller in San Francisco who had amassed a fortune which has now been spent in the collection of materials for his histories.

His labors on the histories of the Western States and of Mexico, which are the standard works on their respective subjects, and his large fortune were virtually contributed for the public benefit.

It is to be hoped that "The Book of the Fair" will meet with the success it deserves. It is handsomely printed, and it will be, beyond its historic value, an ornament to any library.

GENERAL ELECTRIC.

What is Said of It Nowadays.

(From the Boston Evening Telegram.)

GENERAL ELECTRIC ROBBERY.

New England Mulcted for *$50,000,000*. The History of the Most Daring Swindle of Modern Times.

HOW NEW YORK BEAT NEW ENGLAND. $70,000,000 SHRUNK TO $25,000,000, AND STILL SHRINKING.

Common Stock from 120 to 30; Preferred from 120 to 70; Bonds 105 to 60—Will New England Be Further Robbed ?

NO ! BONDHOLDERS WILL ENJOIN DIRECTORS FROM COMPLETING THE WORK OF GUTTING THE TREASURY.

HOW PIERPONT MORGAN PUT COFFIN TO SLEEP.

The *Telegram* has put its agents to work, has started its machinery of investigation, and in a short time will be able to lay before the startled community the following facts : The General Electric Company is an illegal Trust, founded upon a conspiracy to swindle its stock and bond holders.

That the conspiracy was hatched up before the consolidation of Edison and Thomson-Houston Companies.

That the Edison was hopelessly and palpably bankrupt, and that its directors and bankers knew it to be so.

That false statements of its condition were made to the Thomson-Houston people, and that upon such false statements the consolidation was brought about.

That a floating debt of over eight million dollars was not upon the books of the company.

That after consolidating, upon its discovery, bonds of the General Electric Company to the amount were used to pay it.

That the stockholders of the General Electric Company were deceived as to the purpose of the issue of these bonds, and to-day suppose, and have been led to believe, by the directors that the bonds were used for other purposes.

That the floating debt of the General Electric Company to-day is over twelve million dollars.

That its entire assets will not pay its floating debt and forty cents on its bonds.

The inside New Yorkers, or old Edison crowd, sold their stock to the New England holders at over par.

That they sold thousands upon thousands of shares short at par and bought it back at thirty to forty.

That one agent, a Boston operator, sold for them over seventy thousand shares.

That they are preparing to take what is left and then turn the balance or the worthless shell over to a receiver.

That the annual report is false from beginning to end.

That the company is hopelessly bankrupt.

That it has not been able to meet its obligations for the past six weeks.

That the bondholders and unsecured debt holders will ask the courts to enjoin the transfer of the treasury assets and the appointment of a receiver.

That if a receiver is not appointed, New England will not receive one cent on a dollar for its investment.

That the conspiracy has gone so far that President Coffin, the representative of New England interests, has already been replaced by Twombly the New Yorker.

That he has got to join McLeod and the long list of men who have pulled Morgan chestnuts from the fire.

The Armour Institute.

Special Preparations for the Electrical Course.

The Armour Institute at Chicago, which opens September 14, will have a course in electrics which it is believed will place it at once on a par, in this respect, with the best technical schools in the country. The Institute has been a liberal purchaser of laboratory apparatus at the Fair, and its selections have generally been marked by good judgment. Some mistakes seem to have been made in certain apparatus, which, however, can be easily corrected.

Mr. W. M. Stine, the director of this department, is quoted as follows :

"We have bought many thousand dollars' worth of the best apparatus to be purchased, and our laboratory will be beyond doubt not only a model of its kind but the leading collection of electrical test instruments in this part of the world.

"One specialty that we will make is that of measuring instruments, and while foreign apparatus has been generally conceded the best in this line, we also include all apparatus of American manufacture that is good and serviceable."

We would like to know who makes this concession. Certainly not the foreigners, nine out of ten of whom are free to admit that the instruments designed and perfected by an American, Prof. Edward Weston, are the standard throughout the world.

The Mather Electric Company's Election of Officers.

At a recent meeting of the Mather Electric Company of Manchester, Conn., the following officers were elected : Directors—B. A. Simmons, Hartford ; C. N. Knox, Hartford ; Charles B. Whiting, Hartford ; C. T. Welles, Hartford ; F. C. Rockwell, West Hartford ; M. S. Chapman, Manchester, and A. D. Claflin, Boston. At a subsequent meeting of the directors B. A. Simmons was chosen president, M. S. Chapman vice-president, and C. T. Welles secretary and treasurer.

Performance of Street Railway Power Plants.

(Continued.)

BY WM. A. PIKE AND T. W. HUGO.*

Summary of Results, Test. No. 1.

Time of beginning test	4.20 A.M., March 5, 1892
Time of closing test	1.50 A.M., March 6, 1892
Duration of test	21 hours 30 minutes
Engines in use	Two tri-cylinder condensing Allis engines
Boilers in use	Nos. 1, 3, 4, 5, Babcock & Wilcox boilers
Total water as evaporated	525,487 lbs.
Less 1½ per cent. average moisture	517,601 lbs.
Water collected from separator No. 1	5,778 lbs.
Water collected from separator No. 2	1,896 lbs.
Water collected from both	7,674 lbs.
Steam condensed in empty Stirling boiler No. 1 (leaky valve)	3,024 lbs.
Water collected from jackets	47,129 lbs.
Total dry steam used in engines not including jackets	459,773 lbs.
Total oil used	44,245 lbs.
Average temperature of feed water	123.4 degs.
Average steam pressure in boiler room	122.4 lbs.
Average temperature of flue gases	385 degs.
Average temperature of boiler room	82.5 degs.
Average draught in flue	¾ inch
Average height of barometer	28.77 inches
Average temperature of oil	101.7 degs.
Average moisture in steam	1½ p. c.
Average temperature of injection water (about)	38 degs.
Average revolutions per minute, engine No. 1	62.26
Average revolutions per minute, engine No 2	63.00
Average horse-power, engine No. 1	705.88
Average horse-power, engine No. 2	621.23
Maximum horse-power at any time, engine No. 1. [at 7.50 P.M.]	1,097.30
Maximum horse-power at any time, engine No. 2 [at 5.50 P.M.]	1,040.96
Maximum horse-power at any time, both engines [at 5.50 P. M.]	2,046.2
Average total horse-power during run, both engines	1,237.9
Average horse-power used for lighting purposes	33.4
Average total horse-power during run available for car use	1,204.5
Average horse power used by condenser engines	13.66
Average electric horse-power	1,088.00
Ratio of horse-power of condenser engines to horse-power of main engines	1 1-10 p. c.
Ratio of total steam used in jackets to steam used in cylinders	9 15-100 p. c.
Loss by friction between engines and line, obtained by taking the difference between steam and electric horse-power	149.00
Loss by friction in per cent	12 2-10 per cent.

The power used by the condenser engines was practically constant under all variations of load on the main engines.

In calculating the ratio of steam used in jackets to that used in the cylinders of the main engines the water collected by the separators was deducted from the amount chargeable to the boilers, also the leakage from the leaky valve before noted.

Average water used in Stirling boiler for condenser engines, pumps and heating system, per hour	5,837.6 lbs.
Average water used in main engines, without jackets, per hour	21,385.0 lbs.
Steam used in cylinder per horse-power per hour, as evaporated	17.29 lbs.
Steam used in cylinders per horse-power per hour, from and at 212 degs	19.54 lbs.
Steam used in cylinders and jackets per horse-power per hour, as evaporated	19.05 lbs.
Steam used in cylinder and jackets per horse-power per hour, from and at 212 degs	21.52 lbs.
Evaporation of water per pound of oil, as usual	11.87 lbs.
Evaporation of water per pound of oil, from and at 212 degs	13.50 lbs.
The oil analyses show a possible evaporation of water from and at 212 degs. of	20.64 lbs.

Taking 20.64 lbs. as the evaporative power of the oil and 15 lbs. as that of standard coal, the above evaporation is equivalent to 9.79 lbs. of water per pound of coal, from and at 212 degs.

Standard oil is considered to have an evaporative power, from and at 212 degs., of 22.00 lbs.

Cost per Horse-Power.

Cost of fuel oil for main engines, using steam of 1½ per cent. saturation, with fuel oil costing $0.0226 per gal., weighing 6 3-10 lbs. per gal., per day	$157.85
Cost of fuel oil for main engines, if using dry steam, and with condensation in main steam-pipe deducted	154.06
Cost of fuel oil for condensers, pumps and heaters	39.05
Cost of labor per day, exclusive of chief engineer and electrician	51.50
Cost of lubricating oil and waste [figures from office]	14.71
Total cost per day, exclusive of any water purchased	$263.11
Cost per hour of run	12.24
Cost per total horse-power per hour	0.0099
Cost per horse-power per hour on the line	0.01125

Cost of Power per Car Mile, per Car Hour, and per Passenger—Minneapolis, March 5, 1892 :

Total cost per day	$263.11
Total mileage [from auditor's office]	17,451
Cost per car mile	$0.0151
Total car hours	2,435.16
Cost per car hour	$0.108
Total number of passengers [auditor]	66,990
Cost per passenger	$0.00392

In comparing these figures with those obtained in the other tests, it should be remembered that the cost of heating the building and fuel oil is herein included.

TEST NO. 2—ST. PAUL, MARCH 23, 1892.

The plant at St. Paul consists of three tri-cylinder cross connected engines of similar design to those used in "Test No. 1," but with 48 inches stroke of pistons, and six Babcock & Wilcox boilers; two boilers, however, supplying the steam to the main engines exclusively, of similar dimensions to those used in "Test No. 1," and in all but a few cases, specially referred to, the conditions were the same as in "Test No. 1."

From the fly-wheel pulley on each of the engines two belts 40 inches wide run over 40-inch by 40-inch tightener pulleys, on the slack side of the belt, to pulleys 48 inches diameter by 40 inches face. These pulleys are on 6-inch shafts, making 540 revolutions per minute. Driven by each 48-inch by 40-inch pulley is a generator attached to the pulley shaft by two 6-arm clutches, by which they can be disconnected at will.

Pantographs were used, instead of the pendulum motion of "Test. No. 1."

No separators were used, and the steam piping was all overhead.

Summary of Results—Test No. 2, St. Paul.

Time of beginning test	4.40 A.M., March 23, 1892
Time of closing test	2.00 A.M., March 24, 1892
Duration of test	21 hours 20 minutes
Engines in use	Two tri-cylinder condensing Allis engines
Boilers in use	Nos. 1 and 2 Babcock & Wilcox
Total water evaporated	315,755 lbs.
Less 4-10 per cent. average moisture	308,177 lbs.
Less 1,748 lbs., collected from header	306,429 lbs.
Water collected from jackets	40,909 lbs.
Total dry steam used in engines [not including jackets]	265.520 lbs.
Total oil used	25,850 lbs.

---

* Abstract of paper read at the Chicago Meeting of the American Society of Mechanical Engineers.

Average temperature of feed water	155 degs.
Average steam-pressure in boiler room	128 lbs.
Average temperature of flue gases	342 degs.
Average temperature of boiler room	77 degs.
Average draught in flue	$\frac{5}{8}$ inch.
Average height of barometer	28.64 inches
Average temperature of oil	66 degs.
Average moisture in steam	2 4-10 p. c.
Average temperature of injection water	41.3 degs.
Average revolutions per minute, engine No. 2	69.8
Average revolutions per minute, engine No. 3	69.4
Average horse-power, engine No. 2	418.47
Average horse-power, engine No. 3	427.53
Maximum horse-power at any time, engine No. 2, [6 20 P. M.]	822 3
Maximum horse-power at any time, engine No. 3 [8.00 P. M.]	807.0
Average total horse-power during run available. for car use	756.2
Average total horse-power used by condenser engines	11.51
Average total electric horse-power	694.7
Ratio of horse-power of condenser engines to horse-power of main engines	1 52-100 p. c.
Ratio of total steam used in jackets to steam used in cylinders	13 4-100 p. c.
Loss by friction between engines and line, obtained by taking difference between steam and electric horse-power	131.5 H. P.
Loss by friction in per cent	17 4-10 p. c.

It is believed that the loss in friction here given, as obtained by difference between mechanical and electrical horse-power, is too low, as it will be seen, by reference to the diagram, that during the early morning and late at night, when the engines are running light, the difference between the two is very small, and even occasionally minus. This, it seems to the writers, is due to the imperfect regulation of the engines, it appearing to be a fact that the steam required under these circumstances is admitted in occasional puffs, as the governor occasionally opens the admission valve too wide, then remaining nearly closed for a much longer period. In this way, the cards obtained would be likely, as a general thing, to indicate less power than the engines are really exerting, and hence the friction loss would generally appear less than it really is.

Several sets of friction cards have been taken from these engines since the test, giving a loss of about 137 H. P. to each engine and the line shaft and generators run by it. This would give as an average loss by friction for the whole run 258 H. P., or a little over 20 per cent., which amount will be used later in comparing these engines with those at the Thirty-first Street Station, Minneapolis.

Average water used in auxiliary boiler for condensers, pumps and atomizers, per hour, as evaporated	2,673.1 lbs.
Average water used in main engines, as evaporated, per hour, without jackets	12,447. lbs.
Steam used in cylinders, per horse-power per hour, as evaporated	16.46 lbs.
Steam used in cylinders, per horse-power per hour, from and at 212 degs	18.15 lbs.
Steam used in cylinders and jackets, per horse-power per hour, as evaporated	19.00 lbs.
Steam used in cylinders and jackets, per horse-power per hour, from and at 212 degs	20.95 lbs.
Evaporation of water per lb. of oil, as used	11.54 lbs.
Evaporation of water per lb. of oil, from and at 212 degs	12.73 lbs.

Cost per Horse-Power.

Cost of fuel oil for main engines, using steam of 2 4-10 per cent. saturation, with fuel oil costing $0.0226 per gallon, and weighing 6 3-10 lbs. per gallon, per day	$92.21
Cost of fuel oil for main engines, if using dry steam	90.00
Cost of fuel oil for condensers, pumps and atomizers	19.39
Cost of labor, exclusive of chief engineer and electrician	23.83
Cost of lubricating oil and waste [figures from office]	7.82
Total cost per day, exclusive of any water purchased	143.25
Cost per hour of run	6.71
Cost per total horse power per hour	0.00687
Cost per horse power on the line, per hour	0.01014

Cost of Power per Car Mile, per Car Hour, and per Passenger—St. Paul, March 23, 1892.

Total cost per day	$143.25
Total mileage [from auditor's office]	9,848.
Cost per mile	$0 01443
Total car hours	99,055.
Cost per car hour	$0.1446
Total number of passengers [auditor]	28,825.
Cost per passenger	$0.004969

TEST NO. 2*b*—ST. PAUL POWER HOUSE, MAY 12, 1892.

Object of Test:

This test was made to ascertain the steam consumption of the condenser engines used in tests No. 1 and No. 2. The steam from one Babcock & Wilcox boiler supplied the two condensing engines exclusively, and the water was weighed, as usual in these tests.

Duration of test, in hours	7.11
Total water used, as evaporated	7,859.00 lbs.
Moisture in steam	2 8-10 p. c.
Total dry steam, as evaporated	7,640.00 lbs.
Dry steam per hour, as evaporated	1,074 5 lbs.
Average total horse-power	14 03
Average temperature of feed water	160 degs.
Average pressure of steam	127.4 lbs.
Dry steam per horse-power per hour, as evaporated	76.58 lbs.
Dry steam per horse-power per hour, from and at 212 degs	88.14 lbs.

TEST NO. 2*c*, USING COAL — ST. PAUL, MINN., MARCH 28, 1892.

Average moisture in steam	4.8 p. c.
Total coal	35,750 lbs.
Total ash	2,451 lbs.
Coal burned	33,299 lbs.
Feed water	224,564 lbs.
Average temparature feed water	82.15 degs.
Average steam pressure	121.5 lbs.
Feed water, less 4.8 per cent	213,735.
Feed water, from and at 212 degs	250,769.8
Water per pound coal evaporated	6 4
Water per pound coal, from and at 212 degs	7.5
Extra cost over oil for labor per day, burning coal	$8.37
Extra cost during thirteen hours' run	$5.10
Cost of labor, lubricating oil, and waste as usual for thirteen hours' run	$19.29
Total cost of labor, lubricating oil and waste, burning coal thirteen hours	$24.39
Cost of coal at $4.85 per ton	86.69
Add proportion of coal for condensing engines, pumps and atomizers as evaporated	18.69
	$129.77
Cost to evaporate 1 lb. water	0.000423
Cost per indicated horse-power per hour	0 010659
Cost per average horse power on line	0.01294
Ratio of cost of power burning coal to cost burning oil 120 : 100, or coal cost more than oil	20 p.c.

Relative Cost of Power Burning Oil at $0.0226 per Gallon and Burning Coal at Prices Varying from $2.00 to $4.85 per Ton, Assuming an Evaporation from the Coal of $7\frac{1}{2}$ lbs. Water from and at 212 degs.

Coal at $2.00 per Ton.

Cost per horse power per hour	$0.005631
Saving over oil	37 1-10 p.c.

Coal at $2.25 per Ton.

Cost per horse-power per hour	$0.006099
Saving over oil	31 9-10 p.c.

Coal at $2.50 per Ton.

Cost per horse-power per hour	$0.00655
Saving over oil	26 9-10 p.c.

Coal at $3.00 per Ton.

Cost per horse power per hour	$0.007452
Saving over oil	16 7-10 p.c.

Coal at $3.50 per Ton.

Cost per horse-power per hour	$0.008354
Saving over oil	6 6-10 p.c.

Coal at $4.00 per Ton.

Cost per horse-power per hour	$0.009256
Cost above oil	3 4-10 p.c.

Coal at $4.50 per Ton.

Cost per horse-power per hour	$0.010158
Cost above oil	13 5 10 c.p.

Coal at $4.85 per Ton.

Cost per horse-power per hour	$0.01069
Cost above oil	19 5-10 p.c.

From these figures the relative economy of any coal, the evaporating power of which is known, can be computed.

For example, a coal which has an evaporating power of only $\frac{4}{5}$ of that stated would be equivalent to coal at $\frac{5}{4}$ the price.

Thus, if coal that can be bought for $2.00 per ton requires $1\frac{1}{4}$ tons to evaporate as much as (1) ton of Youghiogheny, it is equivalent to coal costing $2.50 per ton, or the saving over oil would be $26\frac{9}{10}$ per cent.

TEST NO. 2*d*—ST. PAUL POWER HOUSE, JULY 23, 1892.

Object of Test.

This test was made to ascertain the relative value of hard coal screenings (with about $2\frac{8}{10}$ per cent. of bituminous screenings) at $1.40 per ton, and oil at $0.0258 and $0.0261 per gallon; and to obtain the efficiency of the engine, when one engine was doing all the work, more generators having been added to each engine.

Duration of the Test.

The test began at 9.15 A.M. and closed at 7.15 P.M., a period of ten hours.

The boilers were in good condition and the fires left at the close in the same condition as at starting. Besides the observations taken in the boiler room, indicator diagrams were taken on the tri-cylinder condensing engine No. 3, which was furnishing power to the road; also ammeter readings to obtain the useful or electric horse-power.

Summary of Results.

Total water furnished boilers	201,928 lbs.
Percentage of moisture	2 66-100
Net water evaporated	196,582 lbs.
Average steam pressure	127 lbs.
Average temperature of feed water	178.4 degs.
Equivalent water from and at 212 degs	212,154 lbs.
Total coal consumed	34,318 lbs.
Water as evaporated per pound coal	5.72 lbs.
Equivalent water from and at 212 degs	6.18 lbs.

Indicator Records taken from 10 a. m. to 5.20 p. m.

Average horse-power for whole period	859.73
Total water for this period, less 2 66-100 moisture	138,695 lbs.
Water per hour	18,912 lbs.
Water as evaporated per horse-power per hour.	21.99 lbs.
Water from and at 212 degs. per horse-power per hour	23.74 lbs.

Period from 3.20 to 5.20.

Average horse-power	892.36
Total water evaporated	35,472 lbs.
Water as evaporated per horse-power per hour	20.42 lbs.
Water from and at 212 degs. per horse-power per hour	22.05 lbs.

Average Electrical Horse-Power.

From 10 A.M. to 5.20 P.M	737.35
From 3.20 to 5.20 P.M	812.20

Horse-Power Used in Friction: Obtained by Taking Three (3) Sets of Cards for Each Case.

No load on generators	164.43
Generators dead	187.51
Clutches thrown off	150.96
Per cent. of friction to total horse-power, 164.43 : 859.73	19.12 p. c.

It will be noticed in this connection that more horse-power is required after the "clutches are thrown off" than when the "generators are dead"; that is when the switch on the generator is thrown and no electricity is being generated. This feature has been observed so often that unless it be due to some effect of the magnetism of the fields the inertia of the moving parts will possibly be responsible.

Extra Help Required to Handle Coal.

Four firemen at $2.00 per day, per month	$240.00
Two coal-handlers at $55 00 per month	110.00
Extra per day	11.66
Extra per hour, 21 1-3 hours per day	0.55

Cost per Horse-Power per Hour.

34,318 lbs. coal, as above, at $1.40 per ton......per day	$24.02
Cost per hour for coal	2.40
Cost per hour for labor, as usual	1.12
Extra for labor, as above	.55
Waste and lubricating oil per hour	.36
Total cost per hour	$4.43
Cost per horse-power per hour	$0.00515
Cost per horse-power per hour, burning oil at $0.0261 per gallon, from Test No. 2	.009952
Saving over oil as above, when burning screenings	48 3-10 p.c.
Cost per horse-power burning oil at $0.0258 per gallon	$.00986
Saving	47 8-10

Effect on Efficiency of Running Engine Nearer its Rating than in Test No. 2.

Total water per horse-power per hour, including condensers, atomizers, etc., as above	23.74 lbs.
Total water for same, from Test No. 2	25.43 lbs.
Saving due to proper loading	6 7-10 p.c.

TEST NO. 2*e*—EFFECT OF STEAM-JACKETS ON STEAM CONSUMPTION.

On the 28th of March a run of 13 hours was made without steam in the jackets, and the total water consumed was 211,461 lbs., or an equivalent of 232,812 lbs. from and at 212 degs.

The average horse-power for the 13 hours was 1,018.6, giving consumption of water, as evaporated, 16.00 lbs. per horse-power per hour, or an equivalent of 17.62 lbs. from and at 212 degs., as compared with a consumption of 20.95 lbs. per horse-power per hour from and at 212 degs., with steam-jackets in operation, and the steam used therein charged up to the engine.

This shows that under those conditions the engines were more efficient by 15.54 per cent. without the jackets, and this accords with the observations of the engineers of the plant.

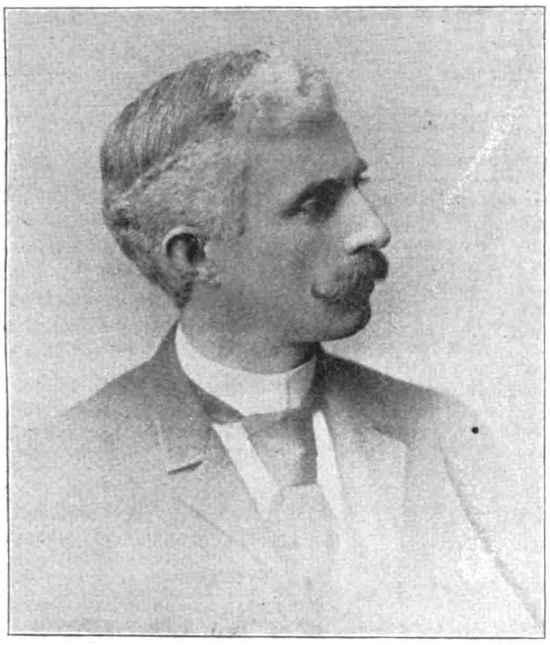
The only objection to these results is the fact that this test did not include the parts of a full day's run when the power was least, and therefore when the engines were least efficient. It is not believed, however, that this would overcome the difference stated above, and the conclusion is forced upon us that under the conditions as then existing the jackets are of no value.

The water of condensation from the steam-jackets was, at the Minneapolis plant, collected in barrels with one platform scale for each jacket, as it was considered possible by having two barrels to handle the water, and it was so done, but entailed considerable manual labor.

Profiting by this experience, a different plan was adopted at St. Paul, which worked perfectly. Two platform scales, each with a barrel on it, was provided for each jacket trap and so arranged that each could be filled separately; and after being weighed, the water was drawn off into a drain under the scales through a pipe and valve inserted in the bottom of the barrel, and while being emptied the other barrel was being filled. The time when each barrel began to receive water, when emptied, and the weight, was noted for each jacket.

With a tight cover on the barrels it was not thought necessary to use cold water to cool the jacket water, and it is not thought that the moisture contained in the slight amount of escaping steam would materially alter the result. Still, when it can be done, it will be found still more satisfactory to cool the water of condensation while being weighed.

(To be continued.)



William E. Nickerson.

Edward E. Cary.

Progressive Woonsocket.

A Large New Building to be Heated by Electricity.

The Woonsocket, R. I., Electric Machine and Power Company already have plans drawn for an imposing brick business structure to be located near the centre of the town. The building will be a two-story structure, 29 feet high. The front will be a pleasing combination of pressed and ornamental brick, copper trimmings, plate glass, handsome stores and imposing entrances, the building having a frontage of 143 feet and a depth of 35 feet.

There will be five stores in the lower story. The upper floor will be devoted to office uses.

The building will be heated throughout by electricity, and is probably the first large building in the State to adopt this method.

Movement for an Electrical Exchange in Cincinnati.

At a meeting of electrical engineers and contractors in Cincinnati last week, steps were taken to organize an electrical exchange in that city. A temporary organization was effected by the election of A. J. Baker as president, and D. J. Hauss as secretary. The secretary was instructed to open correspondence with several Eastern cities where exchanges are already established.

The "New Beacon" Lamp.

The Beacon Vacuum Pump and Electrical Company of Boston, which was engaged in the manufacture of the "Beacon" incandescent lamp until restrained by an injunction granted last February, after a most plucky fight against the General Electric Company, is again to the front offering a new lamp which the makers claim is entirely free from any feature that can be construed into an infringement of any existing lamp whatsoever.

It has been named the "New Beacon" in perpetuation of the title that had become so well known.

In this new lamp the enclosing globe is not made entirely of glass, inasmuch as no glass is used in closing the neck of the lamps, neither do the leading-in wires pass through the glass. These lamps are giving great satisfaction, being already in extensive use.

The "New Beacon," it is claimed by the company, has not been devised merely for the purpose of evading existing patents, but possesses such merits that the company would not now revert to the manufacture of the old style lamps were it free to do so.

No platinum is used in the construction of the "New Beacon." The cost of manufacture is reported less than that of the lamps it supersedes, and it is particularly neat in design.

The Beacon Company is confident in its belief that in its new lamp it has a device against which the charge of infringement cannot be reasonably brought in view of the decisions of the courts up to date.

Having thus produced such an efficient lamp, the Beacon Company has signified its willingness to license other manufacturers to make this new and improved lamp on a basis that will enable them to manufacture—royalty added—at a less cost than the Edison type can now be made, at the same time assuring such manufacturers that their output would be greater than now with the same facilities.

The "New Beacon" lamp is the joint invention of William E. Nickerson and Edward E. Cary, the former the mechanical and chemical expert, the latter the electrical expert of the Beacon Company, and from these joint inventors the company has acquired control of the patent rights, which are said to be comprehensive and controlling.

Inventors of the "New Beacon" Lamp.

Mr. William Emery Nickerson.

The entire electrical fraternity will feel a lively interest in the "New Beacon," and cannot fail to have a desire to get some personal information about the inventors. In the hope of gratifying that wish, we publish herewith portraits of the two gentlemen.

William Emery Nickerson comes of good old New England stock, being born in Provincetown, at the extreme end of Cape Cod, Mass., November 5, 1853.

His earliest school education was obtained in that town, graduating from the High School at a comparatively early age. He subsequently attended classes at the Massachusetts Institute of Technology, where he graduated in 1876 in the Department of Chemistry.

For several years Mr. Nickerson filled the position of Instructor in the Chemical Laboratory of that institution, and was private assistant to Professor Nichols, now deceased, for whom he did a large amount of work on the analyses of water from many different parts of Massachusetts and of air from schools, prisons and railway trains, in the interest of the State Board of Health.

During the years 1877-1886 Mr. Nickerson gained a high reputation among the leather manufacturers of Boston and surrounding districts as an expert in matters pertaining to the leaching of tan bark, the estimating of tannic acid, and other matters incidental to the manufacture of fine leather in its purely scientific aspects.

Although educated as a chemist he has had a wide and varied experience in applied mechanics, having designed and built a number of machines and mechanical appliances for various purposes.

Much attention has been given by Mr. Nickerson to inventions and improvements, so it is not surprising that his name appears more than a hundred times in the list of American patentees. He is quite familiar with Patent Office practice, and always prepares his own patent specifications as well as many for intimate friends, he being well known for his unusual success in drawing specifications and claims which thoroughly define and cover the invention.

It was this gentleman who discovered the principles on which the non-mercurial vacuum pump of the Beacon Company operates, and he is the perfecter and chief inventor of that now well-known machine.

The Beacon Company relies on Mr. Nickerson's genius and skill principally for the solution of its mechanical and chemical problems He does not claim to be an electrician, yet he is exceedingly well posted in many electrical matters.

He is an inventor by nature, his genius constantly running in the direction of producing something new and better in the industrial arts.

Mr. Edward E. Cary.

Edward E. Cary, who, in conjunction with Mr. Nickerson, has evolved the "New Beacon" lamp, first saw the light in Albany, N. Y., February, 1866. His early life was passed in New York City and Brooklyn. In 1884 he graduated from the Brooklyn Polytechnic Institute, and was during 1883-1885 private assistant to Professor Robert Spice, of Brooklyn. The following three years Mr. Cary acted as assistant in Mr. Edward Weston's laboratory at Newark, N. J. In 1888 Mr. Cary identified himself with the Westinghouse Electric Company, and spent three years in the lamp factory of that company at Pittsburgh. During 1891 he was engaged on special filament work in the factory of the Westinghouse Electric Company, at that time located on Twenty-third street, New York City. While thus employed he saw an opportunity for future advancement with the Beacon Vacuum Pump and Electrical Company of Boston, and accepted a flattering offer from that company to take charge of its lamp manufacturing department, a position he still holds.

Mr. Cary, though still quite young in years, has had an unusually fine experience in the art of incandescent lamp making; indeed, he is esteemed as one having no superior in the manipulation of incandescent filaments, his natural talent, thorough education, and wide and varied experience having made him complete master of the art. The standard of excellence attained by the "Beacon" lamp was due in no slight degree to the high-class work done in his special department.

The "New Beacon" lamp is being manufactured with filaments made under Mr. Cary's direction, and as the bulbs are exhausted on the patented pumps owned by the Beacon Company, no further guarantee would appear to be necessary to assure the public that the "New Beacon" will prove an important factor in the situation.

Description of the "New Beacon" Lamp.

The accompanying diagram shows the general construction of the "New Beacon" lamp, and careful reference to the cut and following description will show that the glass globe of the lamp A is provided with a shoulder at B upon which rests a thin disk of mica C. The disk serves as a support for a body of cement D, the composition of which is not disclosed, which is poured, in a fused state, upon it, and completely fills the upper part of the neck of the lamp. This cement is of a novel composition and is not only absolutely impervious to air itself, but makes an equally air tight union or joint with the glass surface of the lamp neck. It is able to withstand the temperature to which it is subjected in the operating lamp without leaking or giving off any gases or vapor whatsoever. It achieves results which although often sought have never before been accomplished. The leading-in wires E E, which are of iron throughout, pass through this cement and through the mica disk C, but nowhere touching the glass of the enclosing globe, and are connected with the filament or burner F at G G. A second disk of mica H is located within the neck of the lamp globe and rests upon the shoulder K. The disk H acts as a reflector, and throws back the heat of the filament, thereby keeping the cement plug from being affected.

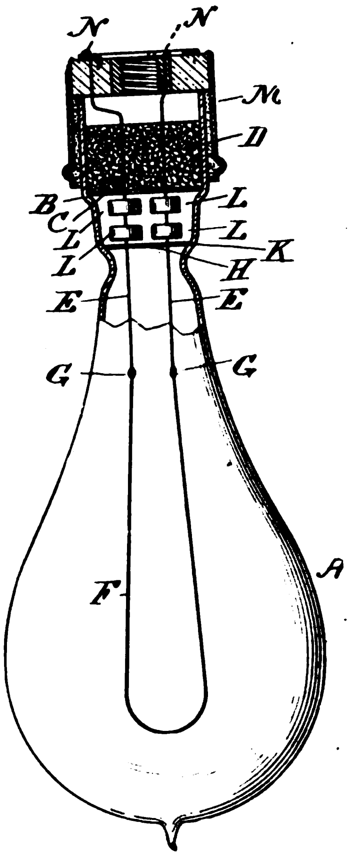
Upon the leading-in wires between the two mica disks are placed small bodies of metal L L L L, called radiators. They are so called because they take up the heat of the leading-in wires and disperse it by radiation, preventing it from being carried into the cement plug. They are a very neat and effective device for the purpose which they accomplish.

The lamp neck is surmounted by a cap or base M of the ordinary kind, fastened in place by plaster of Paris, and to which the leading-in wires are attached by soldering at N N.

While the lamp is burning the cap and socket are nearly as cool as when it is not in operation, a phenomenon not known in other lamps, and the candle power holds up in the same remarkable manner as it did in the old "Beacon" lamp.

The new lamp cannot be excelled for cheapness of manufacture, and with its unsurpassed qualities can scarcely fail to become a popular favorite.

The inventors as well as the Beacon Company are justly proud of the achievement, and believe that they have very nearly attained perfection in the development of an economical and efficient lamp of the modern incandescent type.



The New Beacon Lamp.

Boston Notes.

The dispute between the Old Colony Railway and the Abington and Rockland Electrical Street Railway Companies as to the right to lay tracks across the railway assumed a decidedly sanguinary turn on Wednesday afternoon. Early this week the Old Colony Company engaged nearly 200 Hungarians, Poles and Italians, and kept them in cars near the scene of action under command of an official who had orders to prevent the men employed by the Electric Railway Company from laying tracks across the steam road. Wednesday morning work began and so did the battle, in which nearly 300 men took part. It was no silk-glove fight either, for picks, shovels, axes, clubs, stones and finally revolvers were freely used; some ugly blows were given and received, frightful gashes were made in heads, faces and limbs, the officials having to be carried from the field half killed; blood flowed copiously on both sides and a police force had to be sent from Boston, 19 miles away, to quell the riot. The local hose companies, however, did valiant work in allaying the excitement, for they were summoned to the scene and turned on several powerful streams of water which soon cooled the ardor and courage of the belligerents on both sides. The selectmen of Abington ordered the acting officials of the Old Colony to be arrested, and they were bailed out by the company. Over a dozen men were seriously injured, the doctors being kept busy during and after the melee. Much property was also damaged. The question of who has the right on its side will now be settled by the courts.

The chief offices of the General Electric Company in this city now have a forlorn and somewhat empty aspect about them, as much of the furniture and the clerical staff has been removed to New York, or dispensed with entirely. At the Lynn factories, too, there is a tired feeling apparent, for about one-half the entire staff of workmen have been laid off, those that remain working only three days a week. Under these circumstances, as may be imagined, there is a gloominess prevailing that is decidedly unpleasant, and everybody is wondering what the end will be. Unfortunately for the company so many misleading and contradictory reports have been allowed to issue and be reported that the public now declines to give credence to anything and everything that is either said or printed, it having been painfully realized that "there is a lying spirit abroad." For the sake of the vast number of employees thrown out of work, at any rate, it is generally hoped that a change for the better may take place ere long in the business of this mammoth concern.

The customers of the Malden and Melrose Gas Light Company have petitioned the State Board of Gas and Electric Commissioners with a view to compelling a reduction in charges.

Should the experiments now being made to purify water by electricity at Brewsters, N. Y., prove successful, the system will be adopted for purifying that part of Boston's water supply that is taken from the Mystic River.

The Woburn Electric Light Company, which does extensive business in supplying light and power to several towns and cities and owns a very fine plant, is in a peculiar predicament, its plant having been advertised for sale at auction on Sept. 6, under a foreclosure of mortgage held by Dr. John M. Harlow, of Woburn. The mortgage is said to be for $35,000, the interest on which is long past due.

Suit has been begun at New Haven, Conn., by the General Electric Company against the Winchester Avenue Street Railway Company of New Haven, for damages and profits arising out of the use of a trolley feed wire the patent on which the plaintiff company claims belongs to it exclusively.

The city of Lynn and town of Wakefield will soon be connected by an electric street railway. It will form part of the Lynn and Boston system.

The committee appointed by the City Council of Lynn has formulated an ordinance providing for the placing of all telegraph, telephone and electric light wires underground in that city.

The Maine Street Railway Association was formed in Portland, Me., on Tuesday last, its members including representatives of the ten street railway companies now in operation in that State. Mr. W. B. Wood, of Portland, was appointed president, and Mr. Newman, of that city, secretary and treasurer. The association will take care of the legal and other interests of the different roads.

The incandescent lamp department of the General Electric Company is to be removed from Lynn to Harrison, N. J., and be there included in the former Edison plant.

The Boston and Maine Railroad Company is said to be negotiating with certain electric street railway companies in Maine for the purchase of their roads, with a view to extending them and connecting them with the steam railways at various points, where they will act as feeders.

Mr. Henry Kaliske, the wide-awake manager of the Beacon Vacuum Pump and Electrical Company, reports that the demand for the "New Beacon" lamp is already assuming more than satisfactory proportions. The lamp is now in extensive use and giving unbounded satisfaction. A reason why the lamp was not put on the market earlier was a desire on the part of the company to make every possible test in the laboratory and factory that would prove the efficiency of their new lamp, preferring to defer its introduction to the public until there was not a shadow of doubt remaining that it was as perfect as a lamp could possibly be made.

General News.

What is Going on in the Electrical World.

Omaha, Neb.—The Albright horse car line is to be changed into an electric line.

Syracuse, N. Y.—The Salina street car line will discard horses for electricity after September 4.

Jamaica, L. I.—The trustees of the village have been visiting Hempstead and other places to investigate their arc lighting systems with a view to the introduction of electric light in this village.

Shenandoah, Pa.—The Schuylkill Traction Company expect to have that part of their system lying between Shenandoah and Mahanoy City finished and in operation by the middle of October.

Passaic, N. J.—Nearly two miles of the track has been laid between the county bridge at Passaic and Carlstadt for the new electric railway in that section. The work is being pushed as rapidly as possible.

Bordentown, N. J.—The city councilmen are considering the question of erecting an electric light plant for arc and incandescent lighting of the city and dwellings, and furnishing power to manufacturers.

Dubuque, Iowa.—The Dubuque Light and Traction Company promise to improve their present equipment by additions and otherwise, so as to give the public a street car service that will be satisfactory.

Atchison, Kan.—There is no longer any doubt of the construction of the electric railway. The council has passed the necessary ordinances and a site for the power house has been purchased. Work will begin at once.

Tonawanda, N.Y.—The village council intends to bring proceedings against the Buffalo, North Main Street and Tonawanda Electric Railroad Company to compel them to fulfil the conditions of their franchise.

Dunkirk, N. Y.—As the injunction which prevented the city from putting in the incandescent system of lighting has been removed by the courts, the Water Board, to whom the matter is entrusted, is now at liberty to go on with this municipal enterprise.

Washington, D. C.—Two receivers have been appointed for the Potomac Electric Company—J. G. Darlington at Georgetown, and C. C. Carlin on the Virginia side—the plant and power house being in Alexandria County, Va., and the wires of the company in Georgetown.

Detroit, Mich.—Hereafter all firms which string lighting wires in the streets will have to secure a permit from the city electrician. There are fifteen firms in the city altogether in that kind of business, and a notice has been sent to each embodying certain provisions of the city charter in regard to the supervision to be exercised by the lighting commission.

New Haven, Conn.—The wiring of the Whitney avenue and State street roads is nearly finished, and all that now remains to be done is to stretch the trolley wires. The electric cars will be running before the first of December. The company will begin at once to lay the rails through Lombard and Ferry streets in Fair Haven and then equip that branch of the road.

Milwaukee.—At a meeting of the directors and stockholders held a few days ago a change in the motive power of the Milwaukee and Wauwatosa motor line, was strongly advocated, and will probably be made. The cost of changing the line from steam to electricity, with equipments complete, will be in the neighborhood of $6,000. The company has been talking of making the change for some time.

Louisville, Ky.—The electric suburban service of the Kentucky and Indiana Bridge Company has just been put into operation. Although there is but a single track on the bridge a schedule has been made out to pass over it 565 trains a day, 200 of which are electric suburban trains and the remainder steam trains. The electric trains have two twenty-five horse-power motors each, and are mounted on double steel trucks.

Haverhill, Mass.—An electric railroad scheme is being considered here, connecting Haverhill with Nashua, N. H. It would be a trunk line, with power station at Salem Depot, and branch lines extending to Manchester, Lowell, Lawrence, Chester and desirable points, also a continuation of the line through Winter street in Haverhill to West Newbury and Newburyport. Near Salem Depot are two lakes of great beauty, and the lands around them might easily be made attractive pleasure grounds for the people of the Merrimack Valley.

Evans, Iowa.—The American Coal Company is putting in an electric underground haulage system. The plant includes one 100 horse-power automatic Ide engine, one thirty horse-power and two fifteen horse-power motors and 11,000 feet of trolley wire. When completed this will be the largest plant of its class in Iowa or the West. The daily output of the company will be upwards of 1,600 tons. The haulways of the mines extend over two miles. The plant will have cost when ready for operation over $30,000.

San Diego, Cal.—The San Diego Electric Street Railway Company continues to make additions to the system in spite of dull times. The steam motor which has heretofore supplied means of transit between the ferry and Hotel del Coronado, has been taken off, and the track prepared for electric cars. Poles are being erected and wires stretched, and in a couple of weeks cars between the ferry and hotel will be run by electricity transmitted under the bay from the electric power-house on the San Diego side.

Easton, Pa.—H. S. Cavanaugh, of Easton, counsel for the Philadelphia and Allentown Electric Trunk Railway Company, chartered recently with a capital of $1,000,000, has notified the department of internal affairs at Harrisburg that the whole project had been abandoned because of the lack of funds needed for construction. Mr. Cavanaugh says no part of the road has been or will be built, and that all franchises acquired by the company have become void. It is understood that ex-Mayor Grace, of New York; Thomas J. Swift, of Poughkeepsie; ex-Sheriff Fulmer, of Easton, and others were interested in the project.

Norristown, Pa.—The Norristown Passenger Railway Company were serenaded by the Germanic Band in honor of the introduction of the trolley system in the city. The serenade was given at the Taylor House.—Application was made to the borough council for permission to lay electric railway tracks in several streets here as a part of the proposed line to Philadelphia via Newtown Square, and for which a charter has already been granted with W. J. Fell as president. The charter includes a number of points, namely: Wilmington, Glen Loch, Exton and Kennet Square. The projectors agree to complete and operate the line within two years.

COMMERCIAL PARAGRAPHS.

The interesting World's Fair exhibit of the New England Butt Company of Providence, recently described in Electricity, is attracting throngs of visitors, to many of whom this class of machines is a revelation.

The Standard Electric Company of Chicago, which secured a large slice of the contract for lighting the Fair, has in addition to its service plant an attractive exhibit in the Electricity Building. The machines built by this company are in keeping with its name, as they are in reality Standard Arc Machines.

Mr. W. R. Brixey, manufacturer of Day's Kerite wires and cables, is sending to his customers the Official Catalogue of the Exhibits in the Electricity Building.

The Weston Standard Instruments have naturally been selected by the Jury of Awards at the Fair for making all tests of electrical apparatus.

INCORPORATIONS.

Dr. F. C. Miller, of Tacoma, Wash., Henry Raymond and Eugene H. Lewis, of Portland, Ore., have filed articles of incorporation of the Tacoma Mining and Milling Company. The head office is located in Tacoma. The capital stock is $1,000,000. The trustees for the first six months are Dr. C. Miller, Henry Raymond, Eugene H. Lewis, W. F. Sargent and John S. Stansbury. The company proposes to smelt the iron ore located on the ocean beach near Gray's Harbor by the electrical process of the B. L. and A. Reduction Company.

The Turner Zephyr Stove Company, Indianapolis, Ind.—to trade in natural and artificial gas, electricity and machinery for accomplishing said business, etc. Capital stock, $20,000. Promoters: A. F. Kleinschmidt, Wm. Henry Turner, Wm. Hyde Turner, Indianapolis.

The Domestic Electric Power and Light Company of Baltimore City is the name given to a company recently formed in Baltimore for the purpose of manufacturing and selling Hanson's primary battery, of which Walter Hanson, of England, is the patentee. The company is capitalized at $50,000.

The Telluride Electric Light Company has filed with the Secretary of State of Colorado a certificate amending its articles of incorporation so as to provide for a board of five directors, consisting of R. F. Wrigley, C. W. Corbin, H. R. Woodall, S. R. Fitzgarrald and Wm. Story, and allow the operations of the company to be carried on in San Miguel County.

Las Animas Light, Power and Manufacturing Company, Trinidad, Col.—to increase the lighting facilities of the town of Trinidad, etc. Capital stock, $100,000. Incorporators and directors: Thomas B. Stearns, J. T. Eskridge, Charles F. Lacombe, Henry W. Hobson and Edmund C. Lockwood.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED JULY 25, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

501,968. Electric Railway Trolley. Elmer A. Sperry, Chicago, Ill., assignor to the Sperry Electric Railway Company, Cleveland, Ohio. Filed April 1, 1892.

502,058. Sanding Device for Cars. Nicholas Seibert, Boston, assignor, by direct and mesne assignments, of nineteen twenty-fifths to George F. Malcolm, Allston, and Oliver Eliot Simmons and Siegmund Leipziger, Boston, Mass. Filed Nov. 3, 1892.

502,088. Trolley Wire and Hanger. Earl P. Wetmore, Helena, Mont. Filed Dec. 23, 1892.

502,216. Conduit System for Electric Railways. Frank Wynne, London, England. Filed April 3, 1891.

502,229. Connector for Track Circuits. Edward H. Goodman, Pittsburg, assignor to the Union Switch and Signal Company, Swissvale, Pa. Filed Nov. 1, 1892.

502,243. Electric Railway Trolley. Charles J. Van Depoele, Lynn; Albert Wahl and Charles A. Coffin, executors of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Aug. 9, 1888.

ELECTRIC LIGHTS AND APPLIANCES.

501,911. Carbon Holder for Electric-Arc Lamps. Sigmund Bergmann, New York, N. Y. Filed Oct. 22, 1892.

501,988. Carbon Holder for Electric-Arc Lamps. Frederic D. Hazelton, New York, N. Y., assignor to Sigmund Bergmann, same place. Filed Jan. 10, 1893.

502,166. Electric-Arc Lamp. Patrick J. Barrett, Boston, Mass., assignor of one-half to John J. Frawley, as president of the Boston Society of Redemptorist Fathers, same place. Filed April 5, 1893.

DYNAMOS, MOTORS, ETC.

501,961. Means for Regulating Electric Motors. Charles H. Richardson, Philadelphia, Pa., assignor to the S. S. White Dental Manufacturing Company, same place. Filed Jan. 16, 1893.

502,020. Electric Locomotive. Elmer A. Sperry, Chicago, Ill., assignor to the Sperry Electric Railway Company, Cleveland, Ohio. Filed Oct. 23, 1891.

502,098. Electric Motor for Rotary Drilling Machines. Robert M. Jones, Salt Lake City, Utah. Filed Dec. 22, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

502,091. System of Telephonic Intercommunication. Frank R. Colvin, New York, N. Y. Filed Oct. 15, 1892.

502,262. Telephone Cable. William R. Patterson, Chicago, Ill., assignor to the Western Electric Company, same place. Filed July 30, 1892.

MEASURING INSTRUMENTS.

502,022. Electric Measuring Instrument. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed Feb. 17, 1893.

502,077. Electrical Measuring Instrument. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed March 28, 1893.

SIGNALS AND SIGNALING APPARATUS.

502,207. Electric Signal for Fire-Alarms. Joseph Sachs, New York, N. Y. Filed April 10, 1893.

ELECTROLYTIC APPARATUS.

501,996. Electrolytic Bath. Stephen H. Emmens, London, England. Filed June 17, 1889.

501,997. Apparatus for the Electrolytic Extraction of Metals. Stephen H. Emmens, London, England. Filed July 18, 1889.

MISCELLANEOUS.

501,960. Commutator-Brush. Henry G. Reist, Lynn, assignor to the General Electric Company, Boston, Mass. Filed March 15, 1893.

502,007. Illuminated Sign. Arthur L. McCormick, Port Huron, Mich. Filed Feb. 17, 1893.

502,040. Rheostat. Charles A. Hussey, New York, N. Y. Filed May 23, 1892.

502,083. Junction-Box. Edward J. McEvoy, New York, N. Y., assignor of one-half to the William Cramp & Sons Ship and Engine Building Company, Philadelphia, Pa. Filed Jan. 3, 1893.

502,103. Musical Instrument. Konstantin Polenoff, Nishue Taguilsk, Russia. Filed Sept. 7, 1891.

502,104. Electric Switching Apparatus. Arthur R. Roe, Duluth, Minn., assignor of one-half to George J. Northrop, Marquette, Mich. Filed Sept. 24, 1892.

502,105. Electric Switching Apparatus. Arthur R. Roe, Duluth, Minn. Filed Oct. 28, 1892.

502,156. Self-Winding and Synchronizing Clock. Arthur G. Wiseman, St. Louis, Mo. Filed Oct. 28, 1892.

502,157. Electric-Clock Synchronizer. Arthur G. Wiseman, Webster Grove, Mo. Filed April 29, 1892. Renewed March 24, 1893.

502,215. Electric Winding Attachment for Clocks. Arthur G. Wiseman, St. Louis, Mo. Filed July 30, 1892.

502,246. Combined Phonograph and Coin Operated Mechanism. William S. Burnett, Milwaukee, Wis. Filed Aug. 18, 1890.

RE-ISSUE.

11,354. Dynamo or Motor. Ralston C. Kintzing, Brooklyn, N. Y., assignor to the Crocker-Wheeler Electric Company of New Jersey. Filed Jan. 25, 1893. Original No. 470,057, dated March 1, 1892.

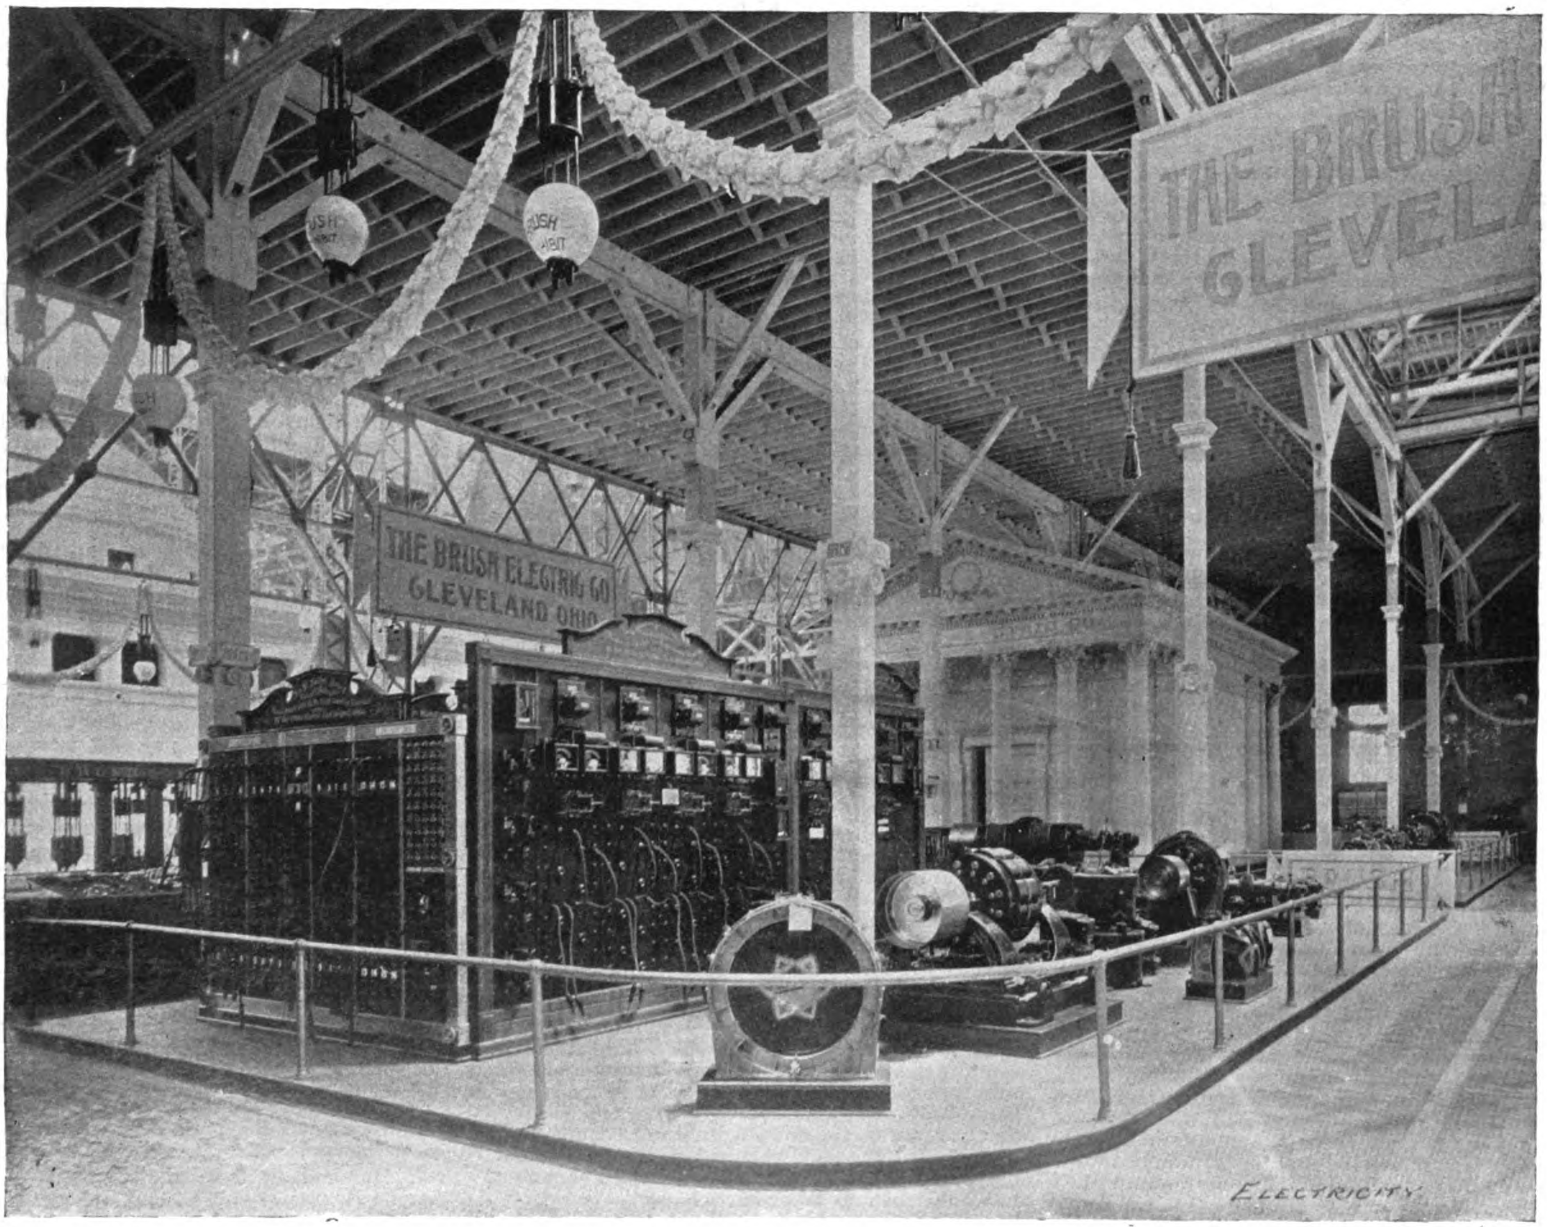
VOL. V. NEW YORK. AUGUST 30, 1893. CHICAGO. No. 7



THE BRUSH ELECTRIC COMPANY'S WORLD'S FAIR EXHIBIT (SEE PAGE 83.)

WORLD'S ELECTRICIANS.

The International Electrical Congress in Session at Chicago.

A NEW EPOCH IN THE PROGRESS OF THE ART.

Synopsis of Proceedings That Will Be of Historic Importance.

ORGANIZATION AND ELECTION OF OFFICERS.

MONDAY, AUGUST 21.

About 2 o'clock P. M. the Art Institute in Chicago was thronged with electricians of almost every nationality, who could be distinguished by a small ribbon badge with the inscription "International Electrical Congress, Chicago, 1893," which decorated the coats of all the members.

At 3:15 Dr. Elisha Gray, chairman of the Committee on Organization, accompanied by Dr. von Helmholtz, ascended the platform in the Hall of Columbus, and was followed by the United States and foreign delegates, and after calling the meeting to order Prof. Gray made a short address, in which he said in substance:

I esteem it an honor of the highest distinction to be permitted to call this International Congress of Electricians to order, coming as you do from all parts of the world, and distinguished, as many of you are, for your contributions to the world's progress through the medium of science, theoretical and applied.

The time and place for the assembling of this Congress are both most opportune. Men who represent the best thought and the best work of the world are here. The scientists who seek to unlock the secrets of nature, and open up to man new fields for research, and further add to the sum of the world's knowledge, are here.

We have here to day men who represent almost every phase of electrical work; men who come from the school, the college, the university, the laboratory of the scientist, and from the commercial walks of life. And then we have with us that other much abused but necessary citizen, the inventor, the man who is, in some degree, a combination of all the rest, and is the product of daylight toil and midnight oil. It is fitting that these varied capacities should come together in a great convention like this.

The rapid strides that have been made in electrical science and electrical invention in the last twenty-five years have marked a new era in our civilization, and this age may well be denominated the Electric Age. Who knows what the next quarter of a century will bring to us through the medium of electricity? To some people it seems as if the limit were nearly reached; but who knows?

The grand results that have thus far been attained were not accomplished by any one nation or individual. We, as Americans, are proud of our native land—the land of Franklin, Morse and Henry; but we are also proud of our fatherland, and we believe that the fatherland is just a little proud of us—although we neither of us say this too often or too loud. The fatherland of America is all the civilized world outside of its own borders. We are proud of an ancestry from which sprang such men as Faraday and Lord Kelvin; such men as Ampere and De la Rive; such men as Galvani and Volta; and last but not least, we are proud of an ancestry that produces such men as our honored guest—Dr. von Helmholtz.

My work as head of the Organizing Committee ends here, and I now surrender this Congress into your hands, feeling assured in advance that the work will be well done; for bad work coming from such an able and distinguished body of men as this is would be an incongruity that is unthinkable.

Upon the conclusion of Prof. Gray's address, Mr. William H. Preece, of London, proposed for temporary chairman the name of Prof. Elihu Thomson, who was unanimously elected. In accepting the nomination he addressed the Congress briefly, after which, on motion of Prof. Cross, Prof. F. B. Crocker was unanimously elected temporary secretary of the Congress.

The next business was the appointment of a Committee on Permanent Organization, and in accordance with the suggestion of the chairman, the following gentlemen were unanimously appointed on this committee:

Dr. T. C. Mendenhall, Washington, D. C.; Prof. Benjamin F. Thomas, Columbus, Ohio; Dr. Louis Duncan, Baltimore, Md.; Dr. S. P. Thompson, England; Prof. E. Hospitalier, France; Dr. A. Lindeck, Germany; Dr. A. Pallaz, Switzerland.

Prof. Thomson then called upon Prof. William E. Ayrton of London, England, who was received with warm applause as he came forward to respond. He addressed the Congress as follows:

There is one thing, ladies and gentlemen, which I certainly am not, which Prof. Thomson has told you I was—namely, a foreigner; for no Englishman can possibly be a foreigner in America.

In asking me to say a few words about a stranger's—not a foreigner's—impression of the electrical display at the Exposition, I imagine that the Committee of the Congress considered it was desirable to precede the more solid meal of mathematical technicalities which we electricians are compelled to feed upon by something a little light; and, therefore, it has fallen upon me to supply the radishes and the caviare which form the first course of the intellectual banquet which the committee have provided for you.

In order that one may judge of this country, it is most important to free oneself from the conservative prejudices so common in an inhabitant of the Old World. I have, therefore, endeavored as far as lay in my power to look upon things here with an open mind. If by chance any of my conclusions may seem a little pointed, I ask you to remember that caviare is made intentionally a little piquant to stimulate your appetite for the more solid dishes that will follow.

Chicago is a long way from the sea, and therefore a vast territory has to be crossed before one can get here. The stranger's impressions of the electrical display of America begin to be formed long before he arrives at the White City. The glow-lamps which he sees lighting even your scattered houses, the arc lamps which he sees burning in your country lanes, the electrical tramways rapidly carrying the working population of your cities into healthy suburbs in the evening when their day's work is over—all these fill the stranger with admiration, and he feels pleased to know that you have no Board of Trade to control your affairs. However, when in a city like Baltimore he finds that the roads which are destined to become electric have been converted into Alpine mountain passes by the construction of electric tramways, when he sees jumbled up in the same posts, telephone, telegraph and high pressure electric light wires, sometimes with insulation a little defective, he becomes reconciled again to the dominion of Whitehall, and he takes comfort to himself in the thought that high pressure transformers are not stuck like flies on the house-walls in his own country. When he learns that the load on the down-town electric mains in New York is at a maximum at 2 in the afternoon, his mouth waters at such a paying load-line, and he would rush to take shares in such a prosperous undertaking except for the recollection that one or a ten per cent. dividend comes to much the same thing when there is no currency whatever to pay the dividend declared. In Pittsburg, Cleveland, Lynn and Schenectady, the stranger is much astonished at the courtesy with which he is shown every detail in a factory as well as at the magnitude of the undertakings. His expectations are roused to such a pitch that he expects when he gets here in Chicago to find an electrical display which will cast all previous electrical exhibitions into the shade.

Well, take this stranger into the Electrical Building blindfolded, so that his judgment may not be warped by the glories of the outside surroundings and leave him there for awhile, if he be candid and if he can muster up courage to say a word which might cause pain to those whose kindness has made them dear to him, he will say that he is a little disappointed. He is disappointed that the world has not better answered the invitation to show in Electricity Building what it could do. If he is an Englishman, he is not only disappointed but rather ashamed of his country. Even looking at the Electricity Building from a purely American standpoint, if you will allow me to say so, I do not think the exhibits inside quite do this country justice. We have all heard of the arrangements that are being made to utilize 300,000 horse-power at Niagara, the greatest engineering feat probably that the world has ever seen; but in the exhibition I think I am right in saying that not a model or a plan can one find of the work that this country is doing, and which will when accomplished redound to its praise. It might seem a small thing, compared with that, to transmit a little over a hundred horse-power 109 miles with a commercial efficiency of 75 per cent.; but at Frankfort the stranger really did see that done; and although that was but a small thing compared with what America is doing at Niagara, one would like to have seen something on the spot. In other words the stranger feels that the real electrical display of America is not in Electricity Building, but in every street where there are trolley wires, in every town and village where there are electric lamps; and where is the town in this country where there are none?

But, if the stranger be thoughtful, he is not disappointed. At Frankfort it was what was inside the Electrical Building that dazzled his mind. At Jackson Park it is what is outside the Electrical Building that rivets his attention One feared that the bustle and hurry of this country would not allow time for the appearance in the programme of its development the cultivation of those charms that Americans come to Europe to witness; but when I saw your Exhibition, when from the top of the Manufactures Building I looked down at night on that "Court of Honor," on that tracery of electric lamps, more beautiful in its realization than could have been even the dream of the writer of the "Arabian Nights," then I felt sure that in that great living hospitable heart which throbs in the breasts of the all-practical, go-ahead people of this country, there must be some nook where lurks the belief that powerful as is machinery, all-powerful as is electricity, the song, the poem, the echo of the statue that lives when the bones of its creator have crumbled into dust, are even more powerful still in forming the history of humanity.

But your Exhibition makes me hope that the love of art and beauty for their own sakes, which we have hitherto regarded as the heritage of poor and oppressed races like those of Italy, Hungary and Russia, will become the heritage of this great free nation.

There is one exhibit in Electricity Building which struck me very forcibly—an exhibit which does not appear in the catalogue—and that is the young American electrician. Deeply interested as I am in the teaching of the application of science to industry, nothing could have pleased me more that to see the value that you electrical engineers of this country attach to the bright lad who has has good college training, and while great feats have been achieved and are being achieved by veterans like Edison, Gray, Elihu Thomson, Westinghouse and others, you trust the development of your electrical enterprises in the hands of those whose skill merits your confidence, whose youth does not cause you distrust.

As one grows older, age, like electric self-induction, wipes out the minor ripples in the current of one's past life, but certain prominences, though rounded with time, are never obliterated. In the current of my life there will ever be one epoch towering far above all others—the epoch labled "Chicago, 1893."

Prof. Mendenhall, from the Committee on Permanent Organization, reported the following officers, who were appointed by a unanimous vote:

Honorary President, His Excellency Dr. H. von Helmholtz, of Berlin, Germany; Permanent Chairman, Dr. Elisha Gray, of Chicago; Vice-Presidents, Edward Weston, United States; W. H. Preece, F.R.S., Great Britain; Prof. E. Mascart, Member of the Academy of Science, France;

Dr. Voigt, Germany; Prof. J. Sahulka, Austria; Prof. Galileo Ferraris, Italy; Prof. H. Weber, Switzerland; Permanent Secretary, Prof. F. B. Crocker, New York.

The list of Vice-Presidents as above given is incomplete because of the non-arrival of some representatives from other countries who have signified their intention of being present. Upon their arrival the list of Vice-Presidents will be completed.

Chairman Thomson escorted to the President's desk Dr. von Helmholtz, the Honorary President elect, who was received with cheers and a rising salute by the Congress, to which he responded in a brief address. After formally accepting the chairmanship of the Congress, Dr. Gray introduced Mr. Preece, who said in part:

> I feel very highly honored in having conferred upon me the position of vice-president for that very tiny little spot on the ocean that is called "Great Britain." This is not the first time that I have crossed the Atlantic. This is not the first Congress that I have attended in America. This is my third visit here, and I have never yet left these shores empty handed. I have always taken something away with me; not surreptitiously, for I think it will be acknowledged that we in England have always handsomely paid for that which we have taken from you.
>
> I have the greatest possible hopes for the success of this Congress. Congresses do an infinity of good. They make us all travel on the same track. We never get shunted into wrong quarters if we rely upon the ideas that have been inculcated at these Congresses. Electricity in all its branches is cosmopolitan. As your Chairman implied, it has no geographical limitations. It knows no nation. It has but one language; and the object of our meeting here is to try to make that language a little more perfect. Its growth and history have been guided by the principle of continuity, and by the principle of evolution, and we are here to show how the modern electrician has planted the ideas of Franklin and Henry and Faraday and Maxwell and others on the history of the present, while we are still working hard to cultivate those seeds planted at our feet by such men as Helmholtz.
>
> But there is one other function that a Congress fulfils, and one which I trust we will do our best to fulfil, and that is to secure amongst ourselves that alone which makes life pleasant and happy—feelings of friendship and of amity. In my small career I have found that the friendships made abroad at these Congresses have been lasting, and can look around me here, and see several of those whom I have met at other Congresses, and whom I know that I shall be able to call my friends as long as we exist.
>
> One of the earliest lessons that I learned in this lesson-teaching country was this: Never prophesy unless you know. Now, I will venture to prophesy this: That when in future ages men shall look back to the annals of history to discover those epoch-marking events that have made history, there will be no assemblage of electricians that will be more indelibly engraved on the marbles of time than this great Electrical Congress of 1893, held in Chicago.

Chairman Gray introduced Vice-President Prof. E. Mascart, of France, who delivered a brief address in his native tongue, thanking the Congress for the honor conferred upon him, and prophesying the greatest good to come from the deliberations of the distinguished scientists there assembled.

Dr. Mendenhall then presented the programme of exercises to be observed by the Congress, after which an adjournment was taken to Tuesday morning.

After adjournment the Chamber of Delegates met to complete their organization, which will meet in secret session, and report the results of their conference at the general meeting on Friday.

TUESDAY'S SESSIONS.

Section A.

Section A, which included the department of Pure Theory, was called to order at 10 o'clock A. M. by Prof. H. A. Rowland of Johns Hopkins University, and the following officers were nominated and unanimously elected:

Chairman, Prof. H. A. Rowland of Johns Hopkins; vice-chairman, Prof. Galileo Ferraris of Italy; secretary, Prof. A. L. Kimball of Amherst College; sectional committee, Prof. A. G. Webster of Clarke University, Alexander Macfarlane of the University of Texas, Charles P. Steinmetz of Yonkers, N. Y.

A permanent organization being effected, Chairman Rowland said:

> We meet here for a discussion of pure science and all will take part in the proceedings. I will ask Prof. Ferraris to say a few words in regard to Italy.

Prof. Ferraris came to the platform, and on being introduced by Chairman Rowland was received with hearty applause. He addressed the section as follows:

> This is my first visit to America. I came here in order to see the New World, where scientific ideas find great applications which result in splendid advancement. I came to take part in the sessions of the Congress which occupy themselves with pure science. It is apparently a contradiction, but it is not a contradiction in fact. The science of electricity is the science which better than any other has demonstrated the mutual relation of pure science and practice, and especially here in America it is difficult—it is impossible—to divide science from practice. It is not only in theory but in the great practice which has been developed here and in their love for science that the great American people exhibit the wonderful results achieved by them in technical science and material wealth.
>
> You see the difficulty with which I express myself in a tongue which is not native to me, but I promise you that I will contribute to the full extent of my power to the objects of the Congress. I thank you for your kindness.

The reading of papers being in order, Chairman Rowland called on Prof. Macfarlane to present the subject, "On the Analytical Treatment of Alternating Currents." Prof. Macfarlane was ready to proceed, but in the absence of a blackboard for diagrams was unable to properly present his paper.

The same objection lying to the presentation of the other papers on the programme, on motion an adjournment was had until 10 o'clock A. M., August 23d.

Section B.

In Section B Prof. Charles R. Cross presided, and on motion appointed a committee consisting of Prof. S. P. Thompson, of London; Dr. Louis Duncan, of Baltimore, and Prof. Hasson, of Chicago, to nominate officers for the section.

Prof. S. P. Thompson made the following report:

"We have the honor to bring in the following report for permanent organization. We propose to continue in the chair Prof. Cross. We propose as secretary of the section the name of Lieut. Reber. We propose as the third member of the executive committee Prof. Dolbear."

After this ticket was elected, Prof. Preece proceeded to the reading of his paper, which after some discussion was followed by Prof. S. P. Thompson's paper on "Ocean Telephony." At the conclusion of this paper the meeting adjourned.

Section C.

The meeting was called to order at 10 o'clock by Prof. Edwin J. Houston, the temporary chairman, and the following officers were elected:

Prof. Edwin J. Houston, permanent chairman; George P. Lowe, of San Francisco, vice-chairman; Prof. E. P. Roberts, of Cleveland, secretary; George W. Blodgett of Boston, Dr. F. A. C. Perrine and Townsend Wolcott, sectional committee of three.

In assuming the position of permanent chairman, Prof. Houston made a short address, and called upon several members of the section who responded briefly.

The regular business of this section commenced with the reading of Mr. Shulze-Berge's paper on "Rotary Mercurial Air Pumps," which was followed by a discussion and adjournment.

WEDNESDAY'S SESSIONS.

Section A.

Section A of the Congress was opened Wednesday morning by Prof. H. A. Rowland, and the first paper read was "The Analytical Treatment of Alternating Currents," by Prof. A. Macfarlane.

The discussion was opened by Prof. Davis, who was followed by Dr. Frederick Bedell and Prof. Rowland. After this Mr. Charles P. Steinmetz was called upon for his paper on "Complex Quantities and their Application in Electrical Engineering." This was followed by the paper of Dr. Albert C. Crehore, entitled "General Discussion of Current Flow in Two Mutually Related Circuits Containing Capacity." At the conclusion of this paper Section A adjourned for the day.

Section B.

Section B was called to order by Chairman Cross, and after the reading and approval of the minutes of the previous meeting the chairman called for the discussion on the paper by Prof. Thompson, on "Ocean Telephony," which had been read the day before. At the conclusion of this discussion the paper by Dr. Lindeck on "Materials for Standard Resistance and their Construction" was read. The discussion of this paper was by Mr. Weston, Prof. Thomson and Dr. Lindeck. Afterwards Mr. Kennelly was called upon for his paper, entitled "Some Measurement of the Temperature Variation in the Electrical Resistance of a Sample of Copper," the discussion of which was postponed to the following day.

Section C.

Section C was called to order by Prof. Houston, and Prof. D. C. Jackson read the paper on "Underground Electric Construction in the United States." The chairman then called upon Mr. M. D. Law to open the debate on Prof. Jackson's paper. Mr. T. G. Lockwood, Mr. Abbott, Mr. Farnum, Mr. Heavysides, Mr. DeCamp and Mr. Blodgett also took part in the discussion. The chairman next introduced Mr. F. Sahulka, whose paper was on "Various Uses of the Electrostatic Voltmeter."

There being no discussion of Mr. Sahulka's paper, the chairman next introduced Prof. L. B. Marks, who read the paper on "the New Incandescent Arc Light." Prof. Nichols, of Cornell University, was called upon to open a discussion of this paper and was followed by Prof. Thomson, Mr. Low, Prof. Marks and others. At the close of this discussion the meeting adjourned until the following morning.

THURSDAY'S SESSIONS.

Section A.

Owing to Prof. Rowland's absence on Thursday morning, Section A was called to order by Secretary Kimball, and Dr. Henry T. Eddy, president of the Rose Polytechnic Institute, was elected temporary chairman of Section A. The first paper of the morning, entitled "Explanation of the Ferranti Phenomenon," was read by its author, Dr. J. Sahulka. At the close of the paper, a recess was taken until 12 o'clock, and owing to the failure to secure a quorum, the section was not called to order again that day.

Section B.

Section B was called to order by Chairman Cross, and after a few remarks by Professor Thomas relative to the discussion of the previous paper, the discussion was continued by Mr. Carl Hering and Professor Patterson.

The next paper on the programme was read by Professor Carhart on a "Pair of Electrostatic Voltmeters," which was discussed by Professor Webster, the chairman and others. The next paper was by Professor A. G. Webster, "On a Method of Governing Electric Motor for Chronographic Purposes," on which there was no discussion. The secretary then read a paper by Professor J. A. Ewing, F.R.S., entitled "Iron for Transformers from a Magnetic Point of View," and a recess was then taken until 12 o'clock, at which time Professor Jamieson presented a paper on "London Electrical Engineering Laboratories," which after a short discussion was followed by Dr. Frederick Bedell on "Transformer Diagrams Experimentally Determined." Mr. Kennelly also read a paper entitled "On an Improved Instrument for Measuring Magnetic Reluctance," at the conclusion of which the session adjourned.

Section C.

Section C was called to order by Professor Houston, who introduced Professor F. B. Crocker; the latter spoke extemporaneously on the subject of "Direct Current Dynamos of Very High Potential." After a short discussion the Chairman called upon Professor Thomson to close the discussion for the time being, and upon Dr. Louis Duncan to open the discussion on "Multiphase Motors." The two subjects being connected with the question of long distance transmission of power, the discussion of both was held jointly. The subject was considered at great length, and occupied the greater part of the morning. The last paper on the programme for this session was by Dr. C. Pollack on the "Conversion of Alternating into Continuous Currents.". Adjournment was then taken.

FRIDAY'S SESSIONS.

Section A.

Section A was called to order by the secretary at 10 o'clock.

The secretary stated that in the absence of the chairman a motion would be received for the election of a temporary chairman, whereupon a delegate nominated Prof. Macfarlane.

Prof. Macfarlane was unanimously elected to the Chair, and on taking his seat called for the reading of the first paper, on "Measuring the Power of Polyphase Currents," by A. Blondel.

The secretary stated that Mr. Blondel was absent, but had left his paper here, and as it was in French it would be better perhaps to have it read by title and appear in the transactions.

The paper was read by title and passed.

The chairman then announced that the next paper on the programme was "Extended Use of the Name Resistance in Alternate Currents," by Prof. W. E. Ayrton.

The secretary stated that as Prof. Ayrton was obliged to be present at the other section, he suggested that the paper be read by title only, which was done.

The session then adjourned.

Section B.

This session, which was devoted entirely to the subject of arc lights, was opened with Prof. Ayrton's paper on the "Variation of the Potential Difference of the Electric Arc with Current, Size of Carbons and Distance Apart." In it he gave the results of an elaborate set of tests with arc lamps. In the discussion Prof. Elihu Thomson gave some interesting experiences with the phenomena of hissing and Dr. Silvanus P. Thompson showed the curve of potentials in relation to the length of the arc.

Mr. Violle read his paper in French; the subject was "Light and Heat of the Arc." His conclusions are that the temperature of the arc is the same as that of the crater, that both are independent of the current, and have a constant value of about 3,500 degrees C. In the discussion, Prof. Elihu Thomson gave some results of experiments with the arc, showing how sapphires may be welded, iridium volatilized, and carbon made plastic.

The next paper, that of Dr. S. P. Thompson, on the "Swinburne-Thompson Unit of Light," was read by title at the suggestion of the author. Prof. B. F. Thomas's paper, on the "Periodic Variation of the Candle Power of Alternating Arc Lights," followed.

Prof. Carhart read his paper on the "Maximum Efficiency of Arc Lamps with Constant Number of Watts" in abstract only.

The meeting closed with the reading by title of two papers in French by M. Blondel, one on new researches with the alternating current arc, another on the constant current arc and its employment as a standard of light, and the last by Prof. Rowland on the "Source and Effects of Harmonics."

Section C.

Section C was called to order by the permanent chairman, Prof. Edwin J. Houston, at 10 o'clock.

On motion of Lieut. Hasson, it was

Resolved, That the secretary of this section be instructed to draw up a letter of thanks to Lieut. Spencer, of the General Electric Company, in acknowledgment of courtesies extended by him to members of the Congress.

Dr. Pollak made a few supplemental remarks to the paper read by him before the section on the preceding day.

The chairman then announced that before passing to the discussion continued from the preceding day, Mr. Freke desired to make a few remarks on Dr. Pollak's paper.

The section then took up the discussion of the various systems for long distance transmission.

The Chairman read by title the name of a paper which was passed on by the proper committee, "A Note on the Variation of the Capacity of Insulated Wires with Temperature," by Prof. Herman T. Hering.

On motion it was

Resolved, That a vote of thanks be tendered to our chairman for the impartial and good-natured way in which he has performed his duties as chairman.

This resolution being carried unanimously, the meeting adjourned.

General Meeting—Hall of Columbus.

Prof. Elisha Gray presiding.

The Chairman—If you will please come to order we will now have the pleasure of listening to the report of the Chamber of Delegates.

Dr. Nichols—Mr. President, Ladies and Gentlemen of the International Electrical Congress and Chamber of Delegates: As you know, in accordance with the provisions laid down in this programme the Chamber of Delegates has considered the questions laid before it and has reached certain decisions. It is my duty as secretary to report to you to-day.

The first question which came before the Chamber of Delegates was the Adoption of Values for Electrical Units.

The following resolutions upon this point were passed by the Chamber of Delegates:

Resolved, That the several Governments represented by the delegates of this International Congress of Electricians be, and are hereby, recommended to formally adopt as legal units of electrical measurements the following: As a Unit of Resistance the International ohm, which is based upon the ohm equal to 10.9 units of resistance of the C. G. S. system of electro-magnetic units, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 14.4521 grammes in mass, of a constant cross sectional area and of the length of 106.3 centimeters.

As a unit of Current the International ampere, which is one-tenth of the unit of current of the C. G. S. system of electro-magnetic units, and which is represented sufficiently well for practical use by the unvarying current which when passed through a solution of nitrate of silver in water and in accordance with accompanying specifications deposits silver at the rate of 0.001118 of a gramme per second.

As a unit of Electromotive Force the International volt, which is the electromotive force that steadily applied to a conductor whose resistance is one international ohm will produce a current of one international ampere, and which is represented sufficiently well for practical use by $\frac{1000}{1434}$ of the electromotive force between the electrodes of the voltaic cell known as Clark's cell at a temperature of 15 degs. C. and prepared in a manner specified.

As a unit of Quantity the International coulomb, which is a quantity of electricity transferred by a current of one International ampere in one second.

As a unit of Capacity, a conductor which is charged to a potential of one International volt by one International coulomb of electricity.

As a unit of Work, a joule, which is 10.7 units of work in the C. G. S. system and which is represented sufficiently well for practical use by the energy expended in one second by an International ohm.

As a unit of Power, the International watt, which is equal to 10.7 units of power in the C. G. S. system, and which is represented sufficiently well for practical use by the work done at the rate of one joule per second.

As the unit of Induction, the henry, which is the induction in the circuit when the electromotive force induced in this circuit is one International volt while the inducing current varies at the rate of one ampere per second.

The committee appointed to consider the standard of light, beg to present the following report: They have had much discussion upon the various forms suggested for practical standards, and in particular upon two forms of lamps known and represented as the Amyl-Acetate lamp of Von Hefner Alteneck and the Pentane lamp of Vernon Harcourt. The only practical lamp actually presented to the committee is the new Von Hefner lamp, which, although it has been laboriously tested at the Riechs-Anstalt and reported accurate to within two per cent., has not received any extended trials in other lands. That thereafter it was reported that the Pentane lamp in its recent improved form was preferred in England for the photometer to gas lights. There is the objection to the Pentane lamp that the composition of the commercial Pentane is not sufficiently well defined and to the Amyl-Acetate lamp that its color is too red in hue; finally, the objection to all open flame lamps is that they are too liable to be influenced by the changes in the pressure and temperature and moisture of the air. It is admitted on the other hand that no electric lamp suitable for use as a convenient practical standard has yet been realized. Under these circumstances there was a sharp division in the committee between those who advocated the Von Hefner lamp as an independent standard and those who desired to the maintain *statu quo* until further researches should have been made in various countries.

It was proposed by Drs. Budde and Lumner that the Hefner lamp, constructed exactly according to the specifications of Mr. Von Hefner Alteneck, be introduced as a provisional, practical standard of light, and that the problem of determining its value in terms of an absolute unity be left to subsequent investigation. On vote this was lost by two votes for and four votes against. The following motion, proposed by Messrs. Palez and Thomson and amended by Drs. Budde and Lumner, was then carried unanimously:

Resolved, That this committee while recognizing the great progress realized in the standard lamp of Von Hefner Alteneck and from important researches made at the Riechs-Anstalt, and also recognizing that other standards have been proposed and are now being tried, and that there are serious objections to every kind of standards in which an open flame is employed; it is, therefore, unable to recommend the adoption at the present time of either the Von Hefner lamp or the Pentane lamp, but recommends that all nations be invited to make researches in common on well defined practical standards and on a convenient realization of the absolute unit.

Signed
J. VIOLLE,
EDW. L. NICHOLS,
A. PALEZ,
SILVANUS P. THOMPSON.

Mr. Preece—The announcement I have to make is a simple one. As president of the Institution of Electrical Engineers in England it is my wish to invite the members of this institution of Electrical Engineers in America to meet me at the Victoria House, in the grounds of the World's Fair, especially as they have done me the great honor to make me an honorary member. There are only two honorary members, and I am one of their body. I have experienced this great difficulty that the addresses of the members of the American Institute or the members of the Congress have not been very carefully kept, therefore I have to invite all the members of this Congress, whether they are the members of the Institute of Electrical Engineers or not, to allow me to have the pleasure of receiving them tomorrow afternoon between the hours of 5 and 7 o'clock in my present British home, Victoria House, World's Fair grounds.

It was moved and seconded that the names of the various parties who had extended courtesies be tendered a vote of thanks.

Dr. von Helmholtz spoke as follows: Ladies and gentlemen : We have performed a work which I hope will have some good fruits for all future time in creating a congruity of the electrical associations of all nations so that scientific and industrial men can understand each other in the simplest and best way. Now, it was rather a hard piece of work in these hot days, these continual meetings of the delegates and members of the Congress, and he who has had the greatest part of these exertions and work on this occasion is our venerable president, Elisha Gray, and therefore I want you to extend to him your thankfulness for this work he has done.

L. Mascart seconded the motion.

Mr. Preece—It is my duty, ladies and gentlemen, to put this proposition to the meeting : it is that a vote of thanks be extended to this fine old man, according to the papers, who, by the way, is a younger man than myself; it is my duty to put this proposition before you. Those in favor of this proposition will kindly say aye. I see there is no use to ask for the contrary vote.

Prof. Gray responded as follows : Gentlemen, I cannot tell you how grateful this is to me. I worked for the last two years in organizing this Congress under many difficulties, and these difficulties have continued right up to the present moment. These steam engines outside don't even give us a chance to express ourselves. Now, before we leave, I want to thank the members of this Congress for the part they have taken, and I want to thank you for the good part you have taken in the difficulties under which you have had to labor and I have had to labor. I think upon the whole the Congress has been very successful, and I trust that you will go away feeling this is true, and that you will think of us kindly. And you, gentlemen, who come from foreign shores, when you go home and look back don't think of only the smoke and noise and high buildings, but think of us over here as having warm hearts. I wish you well and pray that you will have smooth sailing and a warm, hearty welcome to your home and dear ones.

Now, gentlemen, this closes the work of the International Electrical Congress at Chicago in 1893.

I now declare the same adjourned.

The Social Side.

Among the entertainments which occurred during the meeting of the Electrical Congress was the banquet on Thursday evening, August 24, of the American Electricians, in honor of the Foreign Official Delegates to the Congress. The banquet was given in the Grand Pacific Hotel and was well attended, the large dining-room being well filled. Prof. Gray presided, and after the solemn duties of the feast had been fulfilled and the cigars lighted, made a happy address which scored frequent applause. Two toasts were then proposed, one of which was responded to by Dr. von Helmholtz, and the other, in three languages, by Mr. Preece, of England, Prof. Mascart, of France, and Prof. Ferarris, of Italy.

The party was a jovial one and numerous speeches were made during the evening. Prof. Ayrton spoke of the hospitality with which he and his associates from abroad had been received, and Prof. S. P. Thompson jokingly attempted to claim all our distinguished scientific men as his countrymen, and pointed to the fact that even Franklin was an Englishman when he flew his kite. The speeches which followed were all in the happiest strain and the occasion was thoroughly enjoyed by all.

On Friday evening the Congress met at the Agricultural Assembly Rooms at the World's Fair grounds to listen to an experimental lecture by Mr. Nikola Tesla, who explained a new electric generator with a reciprocating armature of very high speed. Several of the machines were shown in operation, and diagrams showing their construction were displayed. Mr. Tesla said that although the machines were only at an early stage of advancement, yet he considered them capable of important development for the reason that their speed could be kept absolutely constant under any condition of load or with any variation in the pressure of the compressed air with which they are driven.

On Saturday afternoon the members of the Congress received special invitation to visit several of the exhibits at the World's Fair. These included the Bell Telephone Company, the Western Electric Company, Prof. Gray's Telautograph, the General Electric Company, the Westinghouse Company, the Ferris Wheel, Libby Glass Works and Scenic Theatre.

At 10 o'clock Prof. Barrett, of the Department of Electricity, tendered a collation to the members of the Congress, which was largely attended and thoroughly enjoyed. A number of speeches were made, and at 12 o'clock the company broke up, thus closing a most pleasant and eventful week.

Wednesday's Trip to the Fair.

The members of the Congress, after the session Wednesday forenoon adjourned, took the whaleback steamer Christopher Columbus to the World's Fair grounds. On their arrival on the Casino pier the members were invited to take a ride on the moving sidewalk, the operation of which aroused considerable interest in the party. After the ride the party was taken over to the exhibit of the Krupp Company, where the members were received by Carl Richter, the German Commissioner, and Mr. Lauter, the representative of the Krupp Company. On invitation of Lieutenant Spencer, a visit was made to the Intramural power-house, and the party was given a ride on the Intramural Railroad to the north end of the grounds where they viewed the parade of the West Point cadets. In the evening, through the courtesy of the Electric Launch Company, the entire party were taken around the lagoons in the electric launches. The members were then taken over to the Ferris Wheel and were introduced to Mr. Ferris, after which a trip was made around the wheel. The surprise of the day was the invitation to the German Village to lunch. On the arrival of the members it was discovered that Mr. W. R. Brixey, of Day's Kerite Wire Company, was the host. After the lunch speeches were made by a number of the guests and the party separated for the day.

THE line of telegraph in Cashmir, between Srinagar and Gilgit, reaches an altitude of 12,000 feet at the summit of the passage of Tragbal. It is probably the most elevated telegraph line in the world.

A Tide-Water Register.

Novel Service at Rouen, France.

A Town-Clock Which Tells the Mariner When He May Sail.

The city of Rouen, France, whose inhabitants are largely sea-going folks, has lately installed an electrical tide-water register, which conveys to every part of the city exact information as to the height of the tides.

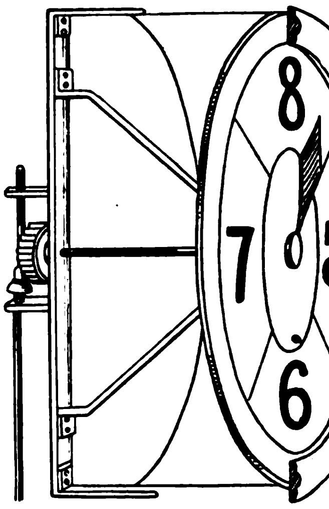


FIG. 1.

The system is very similar in its arrangements to our electric time service.

The Chamber of Commerce, in addition to the series of dials which are distributed to subscribers throughout the city, has erected a central tower with four illuminated dials which can be read from a considerable distance. One of these dials is shown in the illustration (Fig. 1.)

The carrying out of the plan is simplicity itself, the novelty consisting in its conception.

A large iron tube is placed at tide-water, as shown in Fig. 2, containing movable floats, the position of which is registered by electrical mechanism and is simultaneously duplicated on any number of service dials.

While the movement of the tides is calculated in advance, the information is not readily obtainable in smaller towns, and there are many American seaport towns where such a service would be of great value to the inhabitants.

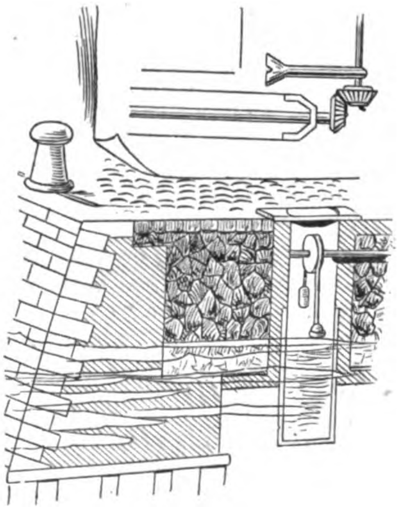

FIG. 2.

Electric Heating.

Probably the most attractive exhibit at the Rhode Island State Fair this year will be an elaborate display of electrical cooking apparatus in practical use. The exhibit will be in charge of graduates from a cooking school.

Mr. H. W. Axford, the incubator man, says he obtains better results by the use of electricity for heating than by any other process yet tried.

Ocean Telephony.

BY SILVANUS P. THOMPSON, D.SC., F.R.S.[*]

The retardation ot signalling, which is found in submarine cables, is due to the capacity of the cable, and this capacity is distributed fairly uniformly along the cable. Owing to this circumstance, all attempts made hitherto to annul or compensate its operation by means of devices situated at the *ends* of the cable, have met with very limited success. Whereas, the ordinary speed of signalling through an Atlantic cable is about eight words or so per minute, it would be quite possible to send 400 words per minute through a line of the same resistance, but destitute of capacity.

The only effective way to annul the retarding effects of a *distributed* capacity is to apply a *distributed* remedy; that is to say, compensating devices *distributively* along the length of the cable, either at intervals or continuously.

It is well known that the effects of electromagnetic induction are, in a sense, reciprocal to those of capacity. If electrostatic capacity can be used to correct the effects of electromagnetic induction, conversely it will be possible to use electromagnetic induction to correct the retarding effects of electrostatic capacity.

There are two main modes of action of electromagnetic induction, namely, *mutual induction*, from wire to wire (with or without an iron core intervening, and sometimes called electrodynamic induction), and *self-induction* when the current in a wire reacts inductively on itself. Both are known to be due to the setting-up, by currents, of magnetic fields in their neighborhood.

There are a very large number of ways in which, theoretically, the end may be obtained of compensating the effect of the distributed capacity by means of distributive electromagnetic induction. It will suffice here to consider two simple cases, and for the sake of simplicity it will by supposed that each is applied to the case of a cable containing two insulated wires for the outgoing and returning currents. Such a cable may be represented in Fig. 1, where AA is the outgoing wire or " line," and BB the incoming wire or return. In the subsequent figures the sheathing will not be specifically indicated.

In the case of self-induction devices used distributively a series of self-induction coils of sufficiently high resistance and sufficiently great inductivity are placed across at intervals from the A conductor to the B conductor. In order the better to follow the action it will be convenient to represent the distributed capacity in Fig. 2. Here the two conductors A_1 A_2, B_1 B_2, are drawn as though each in itself was devoid of capacity, but that a capacity was given to them in a distributive way by arranging a number of condensers along at intervals, each condenser having one coating joined to the A line, and the other coating joined to the B line.

Suppose the signalling to take place from the left-hand end, and that a wave of current is being thrown into the circuit at A_1 by a transmitting apparatus joined to A_1 B_1. Were there no capacity or inductivity in the line A_1 A_2, the waves would travel simply along without retardation. But the presence of capacity changes all this. When the potential at A_1 is rising the potential at some point along the line *a* would not rise simultaneously, because of the capacity in the intervening part of the conductor. The potential at *a* cannot rise to its proper value until the condenser between A_1 and *a* has received its charge. Similarly, the potential at *c* does not rise as soon as at *a*, because of the action of the capacity between *c* and *a*. Again, when the potential at A_1 is falling, it will not also fall at *a* or at *c* simultaneously, because the condensers in between tend to keep up the potential and take time to empty themselves. Whenever the potential at any part of the line is rising, some of the current tends to flow into the condenser at that part, with the result that the rise of potential in that part is delayed, while the current beyond that part is for the moment smaller than the current that is coming up to the part. Further, when the potential at any part is falling there is a tendency for current to flow out of the condenser at that part, and thereby keep up the potential a little later; so that at that moment the current flowing away from the part in question is greater that that flowing towards the part. If nothing is done to compensate this action, the effect would be that virtually all the wave thrown into the cable at A_1 would be taken up in playing into and out of the successive condensers, and so only an insignificant and much-retarded fraction of it would reach the end A_2.

Now, suppose that self-induction coils are placed across the cable at the proper intervals, as in Fig. 3. The operation of these coils in compensating the retarding effect of capacity is as follows: When the potential at *a* rises, current begins to flow through the self-inductive coil *a b*, and this current tends, by the well-known inertia like action of self-induction, to go on after the applied electromotive force producing it has begun to diminish, or has even stopped or reversed. Hence, the current in the self-induction coil *a b* will attain its maximum value at a time after the potential at *a* has begun to fall. It will, by that very circumstance, as a consequence of the electromagnetic momentum, tend to make the potential at *a* fall *sooner* than it otherwise would do. Hence the respective actions of the self-induction coil and of the condenser are of opposite kinds. One tends to cause the changes of potential in the line to occur *later* than they should occur; the other tends to cause the changes of potential to occur sooner than they otherwise would occur. Hence their action tends to compensate one another if applied at the same place. But the capacity of a line or cable is not at one place; it is distributed all along it. Therefore, it is essential that the compensating devices should also be placed all along it, at sufficiently frequent intervals. It is well-known that Varley employed an inductive shunt *at each end* of a cable; but this is not capable of compensating the capacity, except within, at most, a few score miles of the ends. The coil *a b* (Fig. 3) may be looked upon as compensating the capacity on both sides of it to a certain distance; the coil *c d* as compensating the capacity on both sides of it; and so forth. If all these compensators are properly ranged along the cable, then the total retarding effect of the distributed capacity will be practically annulled. The currents that run in and out of the transmitting end will be greater in quantity than those that are delivered in and out at the distant end; the difference being of course accounted for by the currents that flow across through the compensating coils. It will be seen that by the use of these devices a certain fraction of the currents that are sent in at the transmitting end is, so to speak, used up on the way to pass through the compensating coils, and by their action prevents the retardation of the rest of the currents that are flowing down the line. To put the matter tersely, the compensators act as leaks across from the A line to the B line, which by their inductive action sweep out the accumulating charges that would otherwise retard the signals. Some calculations on the magnitude of the currents that must thus flow across in the compensating coils have been made by the author, and some others for him by Dr. Sumpner. From these it appears that taking as a working basis the actual facts about cables as they are, as assuming a twin wire cable having a capacity of $\frac{1}{8}$ microfarad, and a resistance of 10 ohms, for a mile length, also assuming that compensating coils are placed across at every 10 miles, if such coils have a coefficient of self-induction of 100 henrys and a resistance of 3,000 ohms each (its time-constant being then about $\frac{3}{100}$ths of a second), the rise and fall of current in each section will, with currents of the ordinary telephonic periodicity, be practically instantaneous in each section during the very small fraction of a second that the impulse lasts; and the value of the current from section to section will be practically determined solely by the shunting action of the successive compensators. Now, as telephonic currents may be shunted down to an extraordinary degree of tenuity, and yet be perceptible, it is evident that there are great possibilities opened out by this method of using the shunted portions of the current to neutralize the retardation.

FIG. 1

FIG. 2

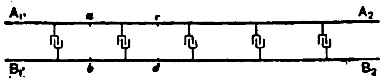

FIG. 3

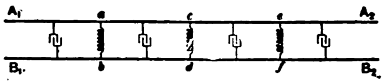

FIG. 4

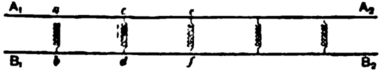

FIG. 5

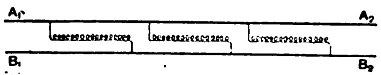

FIG. 6

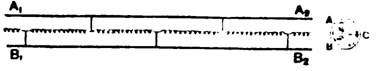

The cable so constructed of two wires with compensating devices shunted across at intervals of 10, 20, or it may be 500 miles apart, will be represented diagrammatically by Fig. 4. The practical problem then remains how to provide compensators having a sufficiently great time-constant without their constituting unwieldy enlargements of the cable. This is a very simple matter of construction. The author has tried several species of devices, some of them resembling elongated " hedgehog " transformers made very long and thin, and wound with one coil only of fine wire; others consisting of " shell " transformers elongated into a very long, narrow loop; others again consisting of simple iron wire, straight or looped, or of wire over-wound with a layer of iron wire. The self-induction, for example, of a one millimetre iron wire, over-wound with a layer of iron wire three millimetres deep, is roughly about 0.1 henry per kilometre; and its resistance is 144 ohms. One point in favor of the use of loaded straight wires as self induction devices is the circumstance that the compensator need not join two adjacent points in the two conductors within the cable, but may lie across as in Fig. 5. This construction, which is specially suitable for cables of moderate length, resolves itself into a three-wire cable, of which one wire is loaded in some way to give it self-induction and resistance, and is connected at intervals alternately to the other two, as in Fig. 6.

As stated above, however, not only by self-induction but by mutual induction, the retarding effects of capacity may be neutralized.

With the use of mutual-induction devices distributively, the cable is considered in sections, each of which is in inductive relation with those on each side of it; and again there are many possible varieties included. One example is as follows:—Let the two conductors along the cable be each divided into a number of equal lengths, and let the parts be joined together by mutual-induction coils, that is to say, by induction coils with two windings each. Though the exigencies of cable-laying will necessitate some very different shape of coil or device as an organ of mutual induction, we may assume these induction coils to be of the familiar form of an iron core surrounded by the two windings. The cable so made of sections will be indicated by Fig. 7.

In this figure it is indicated that the coils are so connected that in the A line when the current is increasing and flowing toward *a*, the inductive action will be causing a current in the next section, which will be at the same instant increasing, flowing, so far as the A line is concerned, in the opposite sense, so that while the potential of the point *a* is rising that of the point *m* is falling. The consequence will be that the currents required to sweep out any accumulated charges due to capacity will not have to travel (as in ordinary cables) all the way from the ends of the cable, but need only travel short distances, never more than the length of half a section. Hence, if a cable 2,000 miles long is cut up into 25 sections of 80 miles each, there should be no more retardation than on an ordinary cable 40 miles in length. It is not needful that both the lines should actually be divided: a virtual division into sections is effected in Fig. 8, where the B line is actually continuous. In this figure *p p* is the primary, and *s s* the secondary (or *vice versa*) of the mutual induction coil. Or the arrangement may be alternated, as in Fig. 9.

Or again, if three conductors are employed—of which one may be the sheathing—the sectioning and use of mutual-induction may be accomplished as shown in Fig. 10.

Here, again, as remarked above, the kind of induction coil which naturally suggests itself as suitable for the purpose in question is something of elongated shape, such as a very elongated loop " shell " transformer, or the " cable " transformer which was suggested for electric lighting purposes by Messrs. Siemens & Halske some years ago. Or, as the author suggested in 1891, by using a mutual induction between the wires of the cables themselves by merely enwrapping them, as they lie side by side, with iron. So that the cable once more becomes an arrangement of three parallel wires, of which two are specially brought into mutual inductive relations to one another, and are joined up at intervals, as indicated in Fig. 11.

Lastly, it is, as is well known, possible to have mutual induction between two wires that do not form part of closed circuits, as in the phonopore of Mr. Langdon Davies.

With the facts already known that the Varley shunt does indeed operate at the ends of a cable to compensate in some measure the effects of capacity near those ends, and that on long land-lines the speed of signalling can be increased by inserting a translator in the middle, or even by a mere leak at some intermediate point, it is remarkable that no one should have suggested hitherto the very simple solutions now proposed. Perhaps the reason is to be found in the intense horror with which all good telegraph engineers regard the idea of having a fault on their line. Deliberately to insert, as the author proposes, a series of faults, as shunts across the cable from the going wire to the return wire, will, to many of them, appear sheer madness. The shunts are not mere faults, however. They are bridges possessing considerable resistance, and, what is more to the point, considerable self-induction. They are not leakages, through the insulation to the sheath, of an unknown amount, and one liable to increase by corrosion ; they are as fixed and determinate as the resistance of the cable itself.

---

[*] Abstract of paper read at the International Electrical Congress, Chicago.

Many experiments have been made in the author's laboratory with arrangements of apparatus set up to imitate by condensers and resistances the retarding properties of actual cables. An example will suffice. A section of artificial cable was made up of a resistance of 7,000 ohms, and a capacity across between line and earth of 10 microfarads. Through this cable not a sound could be transmitted telephonically to a double-pole Bell receiver at the distant end, either with a Blake transmitter (with induction coil) or with a Hunnings transmitter without induction coil. When, however, a single compensating self-induction coil, having a resistance of only 312 ohms, and a time constant of about 0·005 second, was bridged across at an intermediate point, telephonic transmission became at once possible, save for very shrill sounds.

One curious result came out in one of the series of experiments, namely, that those telephonic transmitters which have induction coils in them (the ordinary mutual-induction coils with thick and thin winding), are almost useless for the purpose of cable transmission. Apparently the fine-wire winding has too great a self-induction in series in the circuit to be suitable for this purpose. At any rate, better results were obtained from transmitters of other types. Quite recently the author has got better results from a transmitter in which the ordinary two-wire mutual induction coil was replaced by a single self-induction coil on a plan suggested by him in 1884. It is obvious that in any plan which contemplates the counter-balancing of retardation by shunting (through self-induction coils) a notable fraction of the current may necessitate a new type of transmitter capable of sending telephonic currents of much greater amperage than those ordinarily used in overland telephony.

There exists also much evidence to show that mutual induction by devices properly distributed along a twin-wire cable will also be effective in neutralizing the retardation due to distributed capacity. It is an old and well-established rule that the retardation in a cable is proportional to the square of its length. If one could cut a 2,000 mile cable into two cables of 1,000 miles each, and simply translate or relay the current from one into the other, the retardation of the whole ought to be reduced very materially, perhaps not to one-quarter, but at least to one-half. Only here, again, it is evident that some of the electric energy supplied at one end must be used up in the act of working the translator or relay, however it is constructed, even if it be only a simple mutual induction coil. Therefore, if a cable is cut up into numerous sections, each connected by mutual induction with the next, a considerable fraction of the energy put in at one end may never reach the other, being spent on the road in overcoming the retardations that will otherwise arise. Mutual induction, as is well known, tends always to wipe out the self-induction of both the circuits thus brought together ; but with the most perfect conditions of magnetic circuit, the utmost that the mutual induction can effect is to neutralize the self-induction only of those coils which are acting as mutual inductors. It cannot neutralize the self-induction in parts of the circuit beyond. Hence, for the particular purpose in question—namely, that of enabling the circuit to transmit telephonic signals—the induction devices must not be simple ordinary coils inserted haphazard at intervals ; they must be specially designed and inserted with perfect regularity. And the cable itself must be freed as far as possible from self-induction. *Never, for such a purpose, must a cable be constructed, as Atlantic cables have hitherto been, of a single conductor* (of stranded copper) *surrounded by an iron sheathing* that comes in between the outgoing and the returning parts of the circuit, thus adding an enormous impedance. Happily, in all twin cables where outgoing and returning conductors lie side by side within the sheath, the iron of the sheath, enclosing both, increases the mutual induction between them. In such constructions as Fig. 6 the iron used to increase the self-induction of the wires that act as compensators will of itself increase the mutual induction between the twin conductors if they are properly disposed. The experience gained with alternate-current working is absolutely conclusive as to the efficient action that may be expected in special constructions for future ocean telephony.

FIG. 7

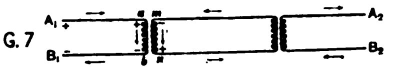

FIG. 8

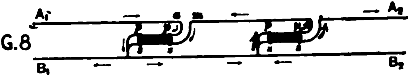

FIG. 9

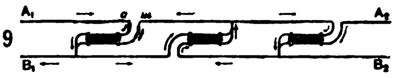

FIG. 10

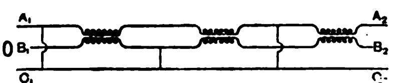

FIG. 11

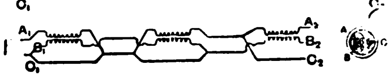

Ocean telephony is possible. The means for attaining it are within our grasp. Compensated cables of the new type are entirely practicable. It may be needful to begin with some shorter line than an Atlantic cable, in order to gain experience. But an Atlantic cable constructed on the new plan will not cost much more, when laid, than one of the old type ; and whether or not it is successful in conveying telephonic speech, it will certainly transmit telegraphic messages at a greatly accelerated speed of signalling. If one Atlantic cable can be constructed to do the work now requiring eight cables, that cable will be constructed. Acceleration of the ocean telegraphic service is in itself a desirable step in advance ; but the advance will not be complete until telephonic speech is transmitted also from shore to shore.

A New Incandescent Arc Light.

BY L. B. MARKS, M.E.*

The *incandescent arc* to be treated of in this paper differs radically from previous forms. In it the electrodes are not in contact, while the current is indirectly used in maintaining all the products of disintegration of the carbon in a state of incandescence or opalescence.

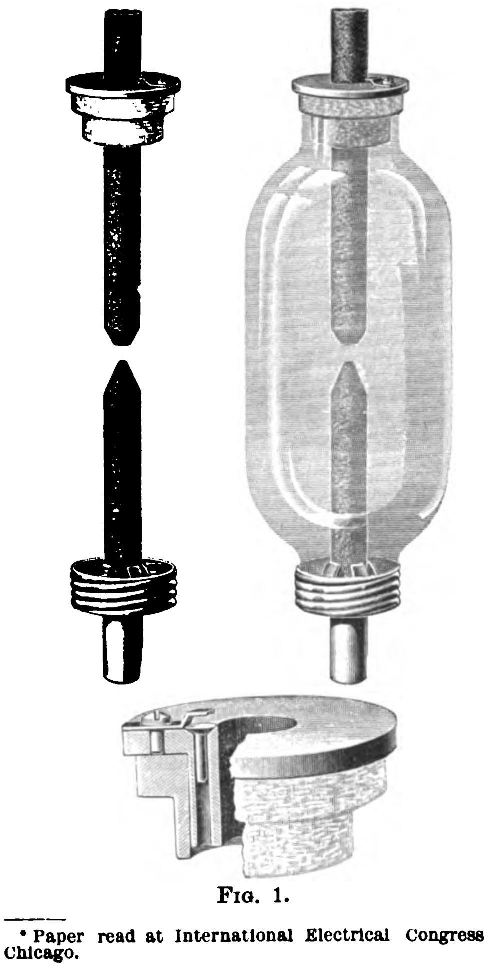

FIG. 1.

Plate A shows the main features of the appurtenance. It will be seen that the arc is enclosed in a small envelope, which is made of highly refractory glass. The envelope is closed at the bottom and provided on top with a metal plug having an opening in it just large enough to admit of the feed of the upper electrode. A fire-proof plug of asbestos-pulp insulates the metal from the glass. A valve, shown in the plate, allows the egress of gas but prevents ingress of the air. With this construction the operation of the lamp will be as follows:

Upon the closure of the circuit, and the springing of the arc, the air in the enclosing envelope is robbed of its oxygen, the latter uniting with the carbon of the electrodes to form C O and C O_2 gases.

The gases are brought to an exceedingly high temperature, at which they maintain the carbon-vapor issuing from the arc. This vapor is deposited in the form of a thin coating on the internal surface of the glass chamber.

The expansive force of the gases may become sufficiently great, if no means of egress be provided, to rupture the envelope; hence, a small safety valve is provided for their outflow. The only possibility of ingress of air is through the narrow space between the positive carbon and the plug; experience has shown that after temperature has been raised beyond a certain point the amount of air that enters in this way is inappreciable : in any event, the oxygen is immediately converted by combination.

It is important that the enclosing glass envelope be as small as possible, for the conservation of the radiant energy, and hence the efficiency, will depend largely upon the size of the chamber. The heat which in the ordinary arc-light is dissipated in the air is here conserved and raises the temperature of the enclosed gases and vapor of carbon. The proper conditions being fulfilled, the lamp maintains its maximum efficiency shortly after the current has been passed through it, and glows like the incandescent with the brilliancy of the arc-light. The arc proper is scarcely visible, but the entire contents of the chamber seem to be luminous, giving the appearance of a solid cylinder of light.

The pressure, as well as the temperature of the enclosed gases has a very important bearing on the performance of the lamp, and affects to a marked degree the character of the carbon deposit on the glass chamber. At this date no definite figures can be given, but it appears that a high tension is absolutely required to give good results.

The structure and constituency of the electrode are also pre-eminently important. Absolute purity of the carbons is imperative.

Investigators in this field have apparently found it impossible to obtain all the requisite conditions. Beardslee[1] mentions a type of lamp similar to the one under discussion, but whether the size or character of the arc-enclosing chamber, the nature or management of the gases, or the quality of the electrodes, or other features, made his arrangement impracticable, is not recorded. Suffice it to say, the comparatively poor grade of arc-light carbon manufactured ten years ago would alone explain his failure.

EFFICIENCY MEASUREMENTS.

Measurements of the efficiency and candle power of the light were made in the laboratory of Cornell University. The method employed in making the efficiency tests was that used by Nakano,[2] in determining the efficiency of the arc lamp, and subsequently by the writer in an investigation on arc light carbons[3]. The ratio of luminous to total radiation of the lamp was taken at different angles below and above the horizontal. The values obtained are given in Table I, where L equals luminous radiation, T equals total radiation, and $\frac{L}{T}$ equals radiant efficiency.

(*Concluded on Page* 82.)

BOSTON:
W S. KEY, - Room 75, 120 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

The International Electrical Congress. The International Electrical Congress, which completed its work with the general meeting held last Friday afternoon, has proved by general consent to be the most important Congress of electricians which has yet been held, and its work, especially that of the Chamber of Delegates, in regard to the names and values of electrical units, cannot fail to be of the greatest value in securing an identical nomenclature for the science of electricity among all the nations represented at this Congress.

Some points, such as the standard unit of light, upon which an agreement was to be desired, still remain open questions. This, however, was due to the lack of sufficiently exact knowledge on these points rather than to any difference of opinion among the delegates, and in view of this the conservative course was adopted of awaiting further developments in these directions.

The papers read were of invariably special interest and treated of many subjects which are being brought prominently before the electrical profession at present for solution, and lively interest was displayed in the discussions of these subjects.

It has been remarked that a great advance has been made in the achievements of each successive International Congress which has been held over those of the previous one, and in this respect the present Congress was no exception to the rule.

The organizing of this Congress, which has been in the hands of several committees, has involved careful and laborious work on the part of many of the members to whose efforts the Congress is largely indebted for its successful results, and especial credit is due to Mr. Carl Hering and Mr. Kennelly for the efforts they have made in this direction.

······o······

The Foreign Delegates. One of the most noticeable features of the Congress was the number of distinguished men of science from all over the world which composed the Chamber of Delegates, and it is not going too far to say that only an event like the World's Fair could make such a meeting possible.

Aside from the scientific interest which attaches to this Congress the social advantages accruing from the meeting of the leading men of all countries in the electrical science will long be felt by the members, and the friendships thus formed will be of the greatest mutual advantage.

The courtesies exchanged between the foreign and home delegates were noticeable. In the Chamber of Delegates the motion to adopt the name of Henry for the unit of Induction was made by Prof. Mascart, in deference to the wishes of the American electricians, notwithstanding a French Congress had already adopted another name for the same unit, and at several informal social meetings our foreign guests took occasion to warmly acknowledge the hospitality which had been extended to them during their visit to Chicago.

The circumstances surrounding this occasion and the distinguished character of its members will make this Congress a feature in the history of electricity whose prominence is unlikely to be eclipsed for many years.

······o······

Long Distance Transmission. One of the most interesting discussions of the Congress took place in Section C on the subject of long distance power transmission by electricity. The discussion was divided between the system of high tension direct currents and multiphase currents, the latter claiming a greater part of the attention.

Prof. Crocker, who has given considerable attention to direct current machines of as high as five thousand or ten thousand volts, explained some of the difficulties in the construction of such machines, and the precautions which are necessary in the methods and the extent of the insulation of the parts.

The polyyhase systems were then taken up, and in the course of this discussion Prof. Forbes explained considerable of the work which is being done at Niagara and the types of machinery which are to be adopted. In the present light he considered the multiphase system to be the most practical factor in power transmission for general distribution. The dynamos for this plant will be of special design as a vertical shaft is required.

A number of different schemes for transmission were considered during the meeting, and the prevailing opinion seemed to favor some form of multiphase currents, although the relative value of two-phase or three-phase currents was in dispute.

The best number of periods per second is an important point which was also considered briefly, the general opinion being that a very low frequency was not compatible with a general system for both arc and incandescent lighting.

Some descriptions of work in this direction were given by a number of foreign engineers, which proved of great interest and will be given in a future issue of ELECTRICITY.

······o······

General Electric. It has not been officially announced, but it is a fact nevertheless, that the most important action taken by the General Electric Directors last week was the appointment of a Committee on Reorganization.

We are not able to predict, at present, whether the proposed organization will tend to strengthen or to weaken the position of the company.

It is also a fact, though not yet announced, that all the district offices of the company, except Chicago, are to be dispensed with.

Mr. H. McK. Twombly, who has been for some weeks *de facto* president and general manager, is taking hold with vigor. His most radical moves so far are not open to public criticism. But that he should consider for one moment, however, the placing of a man like Mr. O. T. Crosby in a position where business experience counts for everything and a technical training for little, shows how easy it is for a good business man, which Mr. Twombly doubtless is, to make serious blunders in conducting an electrical enterprise. Mr. Crosby is a valuable man, but his place is in the workshop, and not in a business office.

We suspect that Mr. Twombly is already convinced of this. He cannot have failed to take notice that since the ill-advised shaking up in the Railway Department the best contract—that at Baltimore for fifty car equipments and three 500 K.W. generators—has been secured by the Westinghouse Company.

Discussion of Mr. Crosby's *business* qualifications excites merriment among his best friends. Any reorganization which places good men in improper places is just as bad judgment from a business standpoint as placing improper men in good places.

Other acts of Mr. Twombly, however, show a better insight into human nature, notably the decapitation of Mr. John I. Beggs, and the semi-official announcement that Mr. E. I. Garfield is also about to walk the plank.

The company received last week $800,000 in cash from the new syndicate, and this is to be followed by four more similar payments. It should also have received $500,000 from the Electrical Corporation.

The directors were in almost continuous session all of last week, beginning on Monday by hearing reports from all the district managers. On Thursday night they did not adjourn until near daylight.

The outcome of the reorganization is yet in doubt, but it will take place in a very short time.

The bitter attack in a Boston paper, written by Mr. Coffin's broker friend, was inspired beyond question. It may have had the desired effect of convincing the New York directors that Mr. Coffin would be a dangerous man to turn loose under present conditions.

The only reorganization which will merit the respect and confidence of the trade at large will be the placing of a man of experience and honesty, a man with thousands of friends and few enemies—such a man, for instance, as Mr. E. H. Johnson—in control of the business affairs of the company. Mr. Twombly should confine his attention to the finances, a subject of which he has knowledge.

……o……

It is at least two months since we have seen any newspaper mention of the Boston Comet, or the Young Napoleon of Electrics.

……o……

The Truth is Coming Out. Last week we had occasion to refer to an attack on General Electric published in a Boston paper. It was in reality an attack on the New York members of the Board of Directors and upon the former Edison management. We expressed the opinion that the matter was instigated by a high official of the company. Subsequent events have confirmed our view, and no denial from him would change our opinion. A pointer on this theory is the following reference to the article from the Boston *News Bureau*, which never prints a General Electric item that is not authorized by the Press Agent.

"Most of this the Boston *News Bureau* has reason to believe is not true. *It is, however, true that the Edison Company was not found after the consolidation to be financially so sound as the Thomson-Houston, and that the New Yorkers have been the main sellers of the stock.*"

If Mr. Coffin is to live comfortably among his old friends and neighbors, it must be proved that he was not personally guilty of humbugging New England investors, and that he was a helpless agent in the hands of the wicked Board of Directors.

By these contemptible methods it is, we believe, sought to prove Mr. Coffin an injured man.

It may work in the rural districts, but not in communities like Boston and New York, where men's wits are sharpened by communion with their fellows.

We think this is about the last we shall ever hear of The Fallen Watchtower, The Shattered Comet, The Young Napoleon of Electrics.

……o……

We have had occasion from time to time to chide the *Electrical World* for its utter lack of moral courage in discussing the affairs of the General Electric Company when that company seemed likely to ride rough-shod over the country, crushing out of existence scores of worthy companies and individual concerns. We still believe that our criticisms, however severe, were fully merited. If the *Electrical World* had done its full duty the Trust scheme would have flattened out months ago, instead of dying by degrees; the trade at large would have had ample opportunity to recover, and the present unfavorable conditions would not have been so serious in their effects.

But while we have emphasized the shortcomings of the oldest of our contemporaries we are not blind to its many good qualities, nor to its meritorious achievements. The issue of the *Electrical World* for August 26 was a credit, not only to its publishers, but to the trade it represents, and we felicitate its distinguished editor, Mr. Nelson Warhorse Perry.

……o……

The announcement of a receivership for the firm of Wallace & Sons will cause genuine grief throughout the trade. The firm's establishment at Ansonia has been for three decades closely connected with the electrical manufacturing business. Twenty years ago it was the common meeting place of many of the pioneers in the art, the scene of many interesting and valuable experiments, and in fact, the very centre of interest. It is indissolubly linked in memory with the early work of William Wallace, Farmer and Maxim, and was unquestionably the source whence Edison and Brush imbibed many of their ideas for subsequent inventions.

It is a pleasure to record the statement of the officers that the company is solvent, will pay its debts in full, and soon be running again. The reputation of these gentlemen leaves no room to doubt the correctness of their statements.

……o……

As was generally expected, the troubles of Wallace & Sons forced the Ansonia Electric Company to seek the protection of the courts temporarily. The statement of the latter company is not yet to hand, but there is no doubt the assets are abundant to protect all creditors. We know that we speak for the trade at large in expressing the hope and the belief that the company will emerge from its difficulties as strong as ever.

……o……

There is business to be picked up by a careful reading of Electricity's "General News" columns every week.

……o……

Mr. Nelson W. Perry, editor of the *Electrical World*, has resigned his position. Mr. Perry's work this summer has been of great value not alone to his paper but to the public. He possesses in a marked degree the genuine newspaper instinct and a wide fund of general information, both grounded upon a solid technical training. Mr. Perry cannot well be spared from electrical journalism.

……o……

A welcome addition to our exchange table is the *Engineering Review*, of London. Vol. I, No. 1, is just at hand, bearing the name of Mr. J. Stephen Jeans as editor. A couple of pages are very properly given up in this number to congratulatory letters from friends of the editor, among whom are H. Bessemer, Andrew Carnegie, W. S. Caine, W. H. Preece and W. T. Stead. The *Engineering Review* will be to engineering what the *Review of Reviews* is to current miscellaneous literature, and a good deal more. It ought to have as many subscribers in America as in England.

……o……

Notwithstanding the circumstance that the Edison General Company was in need of cash at the time of the consolidation, the facts remain that the Edison business was the foundation for the superstructure; that it was Edison assets which saved the Trust from wreck three months ago, and that the Edison business has been the only real profit earner in the combination.

……o……

For the deluded public who lost their money in General Electric there is cold comfort in the accusations of the Boston and New York factions that each was swindled by the other. Electricity hopes that both factions have suffered in pocket, as they have in reputation.

Eugene Phillips's Clambake.

Invitations are out for the fifteenth annual clambake tendered to the fraternity by the American Electrical Works of Providence, R. I., on Saturday next. The festivities of the day will be a very oasis in the desert of dulness and stagnation, and no doubt will be largely attended.

A Modern Cincinnatus.

The following extract from a private letter received from an old newspaper man, Mr. G. W. Pearce, is interesting. The articles referred to are those recently printed in a Boston daily in regard to General Electric affairs:

"Boston, August 23d, 1893.

"B. E. Greene, Esq.:

"*My Dear Sir:* . . . They were written by a State Street broker, who is laboring under the delusion that Mr. Coffin is the innocent victim of the wiles of 'wicked partner' J. Pierpont Morgan. I have not heard anything funnier since I interviewed Rube Burrowes, the Alabama train robber, at Flamington Junction during the yellow fever epidemic at Jacksonville. Rube found out that I was connected with a daily paper having a large circulation, and he requested me to inform my readers that he was not at all the bad man that he was painted, and that if he did steal from rich Yankees on the trains, he never failed to give liberally to the poor Confederate cripples in his county. So it seems by the statements *made by Mr. Coffin's friends* that the worthy ex-shoe man left his bench as Cincinnatus left the plow, to take up arms for his countrymen, and battle against the wicked schemes of Wall Street. Of course everybody in newspaperdom and in financial circles here knew that Coffin would make a silly fiasco of the Electric Trust, which was in the beginning and is now the most asinine organization of dotard speculators that the history of industrial enterprise records in pages blotched with the life blood of trustful investors."

Common Sense from Canada.

(The Canadian Electrician and Mining Review.)

We gather from recent personal interviews with persons interested in electrical matters in the United States, that the line of action taken by the General Electric Company towards manufacturers of incandescent electric lamps is regarded as a huge mistake. Most of the lamp manufacturers stood prepared to pay the General Electric Company a fair royalty on the production of their factories if a liberal disposition had been shown towards them. The attempt to crush them out of existence has aroused the determination that by some means they will survive. The minds of inventors have been stimulated to produce lamps which could not be proved to infringe the Edison patents, and in many instances they have succeeded. This fact, as well as the decision in the case of the Columbian Lamp Company, and the brief period constituting the future life of the Edison patents, has resulted in the entire failure of the coercive policy of the General Electric Company, which is likely to find little comfort in the reflection that its treasury is minus many thousands of dollars which, had its method been more conciliatory, it might have enjoyed possession of.

Receiver for Wallace & Sons.

Abundantly Solvent, but Unable to Get Cash.

Wallace & Sons, manufacturers of brass and copper goods at Ansonia, Conn., with offices at No. 29 Chambers street, New York, have been forced to suspend on account of inability to make collections. Thomas Wallace, treasurer of the concern, and Robert M. Thompson, president of the Orford Copper Company, have been appointed receivers, on the application of John B. Wallace, secretary, and Uri T. Hungerford, manager of the New York office.

The liabilities are placed at $875,000, of which $450,000 is on open accounts and $425,000 on notes. The nominal assets are put down at $2,000,000, of which the plant and machinery are valued at $1,000,000; book accounts, $600,000, which are supposed to be good, and merchandise $400.000.

Following the suspension of Wallace & Sons, the Ansonia Electric Company made application for a receivership, which was granted on Saturday last.

The Franklin-Oil City Electric Road.

The Oil City *Blizzard*, which is published six miles away from the county seat, heads a notice of the Franklin and Oil City Electric Railroad: "All Aboard for Franklin, for Business, Base Ball, Politics, Court or the County Jail."

A New Incandescent Arc Light.

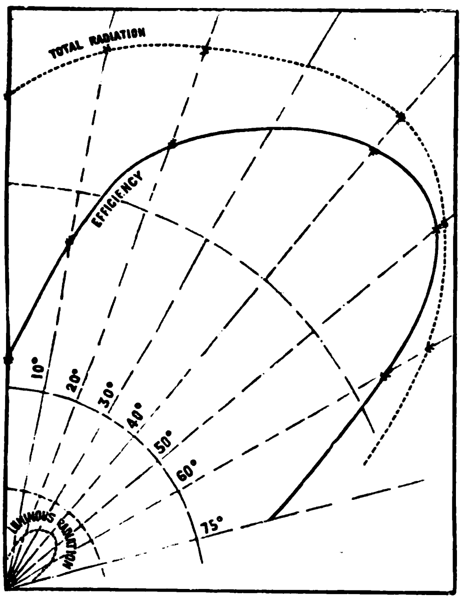

FIG. 2.

values, the dotted line curves showing the distribution of luminous and total radiation respectively, and the full line curve the measure of the efficiency below the horizontal.

The value of the mean hemi-spherical efficiency is obtained by integrating the curve, and is found to be 8.4 per cent. The mean efficiency of the ordinary arc is about 10 per cent.[1] The mean efficiency of the incandescent lamp, according to Merritt[2] is rather below than above 5 per cent. The value obtained in the test of this new light therefore lies between those of the two present forms of electrical illumination, approaching, however, more nearly that of the arc.

While it is true that the average efficiency of the electric arc in open air nets about 10 per cent., it is questionable whether in commercial practice in this country this value is often reached. The writer has made tests of a standard brand of arc light carbon where the efficiency was only $7\frac{3}{4}$ per cent.[3]

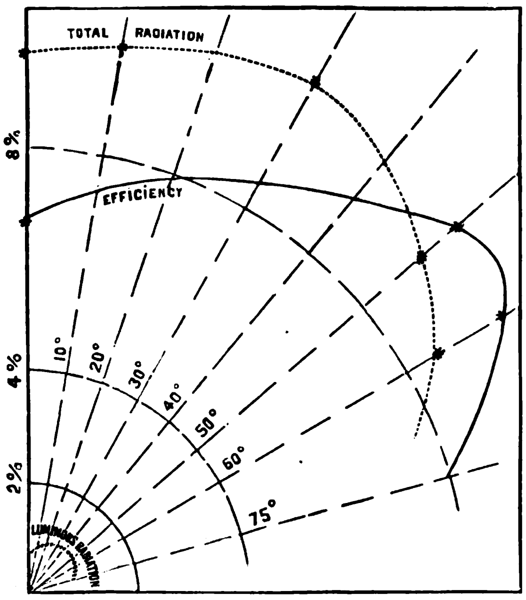

FIG. 3.

Glancing at Fig. 1, we note that while the form of the efficiency curve differs entirely from that of the incandescent lamp, it is not unlike that of the arc. The distribution of light-giving energy is, however, more uniform than in the arc, a fact which is more prominently brought out in comparing the candle power curves of the two. While the approximate law, *Hemi-spherical efficiency*, $= \frac{1}{4}$ *horizontal*, $+ \frac{3}{4}$ *maximum*, holds for the ordinary arc, the mean of several tests indicate that —

Hemi-spherical efficiency $= \frac{1}{2}$ *horizontal* $+ \frac{1}{2}$ *maximum*, fairly represents the conditions manifested by the *incandescent arc*, curves, Figs. 1 and 2.

Tests were made to determine the effect of initially coating the internal surface of the cylinder with various ingredients other than carbon. No marked difference in the efficiency was discovered. Fig. 2, platted from values in Table 2, represents a curve taken in this way. The mean hemi-spherical efficiency was 8.02 per cent.

Table II.—Efficiency Measurements.

(To be continued.)

A Curiosity.

A correspondent of the London *Electrical Review* tells of a 200 C. P. Swan lamp made of green glass for a ship's side light, which has been destroyed by the focussing of heat rays upon it by the reflector placed behind it. The heat has been so intense that the glass was softened, and the vacuum drew it in like the "kick" of a bottle, until the glass was perforated and the carbon consumed. He has another lamp drawn in also, but not perforated, the filament remaining intact. Both were softened on the side next the reflector, so that it is evident that the filament did not touch the glass, but that the mischief was done by the concentration of heat in the focus of the mirror. The green is very dark in the glass, and absorbs a lot of heat.

Performance of Street Railway Power Plants.

(Concluded.)

BY WM. A. PIKE AND T. W. HUGO.*

TEST NO. 3—THIRTY-FIRST STREET STATION, MINNEAPOLIS, OCTOBER 21 AND 26, 1892.

The plant at Thirty-first street consists of ten (10) 16 inches by 27 inches by 16 inches Westinghouse compound engines, nine of which are belted directly to Thomson-Houston generators ; the other is belted to an exciter and to an arc-light machine.

Five of the engines only were in service at the time of the test, and were connected to the main steam-drum in the boiler room by long 8-inch pipes with a number of ells and valves in each.

There are seven (7) Stirling boilers of 287 nominal horse power each. These are connected by 8-inch pipes to the main steam-drum above referred to.

During the first test, boiler No. 7 was disconnected from the steam-drum and used for furnishing steam for pumps, atomizers, etc., and enough of the other boilers were used to furnish steam to the engines.

During the variable load or service test, boiler No. 7 was not used, and the other boilers in service furnished all steam used for engines, pumps and atomizers ; all connections to boilers except those in use were blanked off or known to be tight.

The same apparatus for weighing water, oil, etc., and for determining other data, was used as in the tests of the other plants, except that iron tanks were used for weighing the water and the same precautions taken to insure that the results would be reliable.

Rheostat for Obtaining a Steady Load.

In order to obtain a steady load on these engines, it was first proposed to pass the current through a water rheostat composed of wrought iron rods ¼ inch in diameter, in a tank through which water was kept circulating. It was found, however, that after a short time scale, similar to that deposited in boilers, would collect on the rods and that then they would burn out. To obviate this difficulty, an open-air rheostat was extemporized by Messrs. Cooper and Morell, of the Street Railway Company. This rheostat consisted of 1,200 feet of ½ inch iron rods, clamped together and arranged in two sets of 600 feet each in parallel. This combination was supported on bearers placed across a repair pit in the car house. By this means it was found practicable to obtain a very steady load of any amount required, the only trouble being that in some cases the joints were imperfect, due to the haste in which the rods were put together.

Later tests, with a more carefully constructed rheostat, have given entire satisfaction. In this way a steady load can be obtained much more easily than by means of a friction or Prony brake, wherever engines are used for running generators.

STEADY LOAD TEST, OCTOBER 21, 1892.

It was intended to make a continuous run of eight or ten hours under a steady load, obtained by passing the current from the generators through the water rheostat above referred to. On account, however, of scale forming on the wires the rheostat burned out after a short time, and it became necessary to improvise a new rheostat, as also referred to above. This mishap reduced materially the length of the test under steady load, but the records were so carefully taken that each ten minutes gave results complete in themselves, so that the final results, as given below, are considered to be as accurate as if the actual running time were longer.

Summary of Results.

Duration of test	4 h. 25 m.
Average horse-power	783.3 H. P.
Average steam pressure at boilers	131.5 lbs.
Average steam pressure at engines	118.5 lbs.
Average moisture in steam	4 p. c,
Total water per hour, as evaporated	19,549.5 lbs.
Net dry steam per hour, as evaporated	18,798 lbs.
Average steam per horse-power per hour under above conditions	23.51 lbs.
Probable average steam per hour, if full boiler pressure had been had at engines (loss estimated at 4 p. c.)	22.47 lbs.
Average temperature of feed water	57.44 deg.
Total water furnished main boilers	83,063 lbs.
Amount of water collected from drips and loop.	1,760 lbs.
Net dry steam from main boilers	79,759.7 lbs.
Total water furnished for pumps, atomizers, etc.	14,540 lbs.
Percentage of steam required for pumps, atomizing oil, etc., as compared with steam used in engines, reduced to same pressure	15.9 p. c.

* Abstract of paper read at the Chicago Meeting of the American Society of Mechanical Engineers.

TEST NO. 3—A TEST TO DETERMINE COST OF ATOMIZING OIL.

To settle this question, a run of three and one-half (3½) hours was made October 24, 1892, during which the auxiliary boiler was used to furnish steam for atomizing the fuel oil only, and the amount of steam used for this purpose and also the amount evaporated for the use of the engines determined.

Results.

Total water from boilers used for service	53,734 lbs.
Total water from boilers used only for atomizing oil	8,330.5 lbs.
Average steam pressure in service boilers	132.7 lbs.
Average steam pressure in atomizer boiler	131.8 lbs.
Ratio of water used for atomizing to total water for all purposes	13.4 p. c.

TEST NO. 2*b*—TEST OF PLANT IN ACTUAL SERVICE, OCTOBER 26, 1892—LENGTH OF TEST, 20 HOURS 40 MINUTES.

Total water used in boilers	354,705.4 lbs.
Moisture in steam	4.05 p.c.
Total dry steam	330.517.2 lbs.
Average pressure in boilers	134.4 deg.
Average temperature of feed water	54.4 deg.
Average horse-power	522.5
Maximum horse-power	901.25
Minimum horse-power	77.49
Average dry steam per horse-power per hour	29.2
Average electric horse-power	434.2
Average loss in horse-power between engines and line (by difference)	88.3
Percentage of loss between engines and line	16.9 p. c.
Friction of engine alone in horse-power as determined by friction cards	14.27 h.p.
Percentage as compared with maximum horse-power of any one engine	3 7-10 p. c.
Equivalent water, from and at 212 deg., per pound fuel oil	14.48 lbs.
Equivalent evaporation per pound standard coal	9.87 lbs.
Cost of fuel oil for whole test	$99.07
Total car mileage	6,296.4
Cost for fuel oil per car mile	$.01573

Summary of Result, all Tests—Comparative Cost per Horse-Power per Hour.

From tests made at the Thirty-first Street Station, under the title of "Test No. 3," it is determined that the cost of running the necessary pumps and atomizing the fuel oil is, in percentage of the whole power	15 9-10 p.c.
Cost, in percentage of the whole power, of atomizers	13 4-10 p.c.
Cost, in percentag of the whole power, of pumps.	2 2-10 p.c.
Cost of fuel oil for main engines, "Test No. 1," using steam of 1⅛ per cent. saturation, with fuel oil costing $0.0226 per gallon, weighing 6 3-10 lbs. per gallon, per day, including atomizers	$157.85
Cost of running necessary pumps	3.95
Cost of running condenser engines	6.87
Total cost of power, "Test No. 1," per day	$168.67
Cost of labor, per day	51.50
Cost of lubricating oil and waste, per day	14.71
Total cost per day	$234.88
Cost, as above, per hour	10.92
Cost, as above, per horse-power per hour	$0.00881
Cost, as above, per electric horse-power per hour	0.01004
Cost, as above, per car mile	0.01346
Cost of fuel oil for main engines, "Test No. 2," using steam of 2 4-10 per cent. saturation, with fuel oil costing $0.0226 per gallon, weighing 6 3-10 lbs. per gallon ; per day, not including atomizers	$92.21
Cost of steam for atomizers	12.35
Cost of running necessary pumps	2.30
Cost of running necessary condenser engine	5.75
Total cost of power, "Test No. 2"	$112.61
Cost of labor, per day	23.83
Cost of lubricating oil and waste per day	7.82
Total cost per day	$144.26
Cost, as above, per hour	$6.76
Cost, as above, per horse-power per hour	0.00895
Cost, as above, per electric horse-power per hour	0.01083
Cost, as above, per car mile	0.01464

NOTE.—The slight difference between the cost per horse-power given here, and that from the other test, comes from assuming the cost of atomizing oil, running pumps, condenser engines, etc.—as given by percentages. The results are within less than one per cent. of each other, showing the cost of atomizing, etc.—as obtained directly and by the above percentages—to agree remarkably well.

Cost of fuel for main engines, "Test No. 3," using steam of 4 5-100 per cent. saturation, with fuel oil costing $0.0226 per gallon, 6 3-10 lbs. per gallon, per day, including steam used for atomizers, and necessary pumps	$99.04
Cost of labor, per day	16.83
Cost of lubricating oil and waste, per day	4.02
Total cost per day	$119.89
Cost, as above, per hour	$5.80
Cost, as above, per horse-power per hour	0.01110
Cost, as above, per electric horse-power per hour	0.01336
Cost, as above, per car mile	0.01904

It must be noted here in comparing the cost of power during "Test No. 3" with that of "Test No. 1" and "Test No. 2," that less than half of the power of the plant was used from which the data was obtained for "Test No. 3," and, consequently, the item of labor is somewhat high in proportion to the horse-power developed, for with double the horse-power the labor item would not be materially increased.

Comparison of Cost per Car Mile—Subdivided Power vs. Concentrated Power.

In making this comparison, the results as obtained from the above tests at Thirty-first Street are compared with those obtained from the test of the triple expansion engines at Power House No. 1.

In order that the results may be properly compared, the following assumptions are supposed to apply to both plants, though they were different when the tests were made :

Cost of fuel oil per gallon	$.0257
Evaporation, from and at 212 deg., per pound of oil	14.48 lbs.
Total car mileage to be provided for	17,118
Average horse-power for 21 h. 30 m. for above mileage, Power House No. 1	1,203.5
Average horse-power for 21 h. 30 m. for above mileage, Thirty-first Street Power House	1,173.0

NOTE.—This difference comes from the difference in friction at the two stations. At No. 1 it is estimated at 20 per cent., and at Thirty-first Street at 17 per cent.

The following figures, which are as close as could be obtained from the auditor's office, are the basis of the "fixed charges," which go to moke up total cost, and will serve as basis of comparison.

Value of real-estate and buildings, assumed to be the same for both plants for comparison.	$35,000.00
Value of engines, Power House No. 1	60,000.00
Value of boilers, Power House No. 1	25,000.00
Value of line shafting, Power House No. 1	15.500.00
Value of belting, Power House No. 1	5,000.00
Total	$105,500.00
Value of engines at Thirty-first Street	$35,000.00
Value of boilers at Thirty-first Street	25.000.00
Value of belting at Thirty-first Street	1.500.00
Total	$61,500.00
Rate of interest on investment	6 p. c.
Rate of depreciation on machinery, boilers, etc.	10 p. c.

Cost of Labor, Power House No. 1.

10 men at $55.00 per month	$550.00
4 men at $65.00 per month	260.00
1 man at $75.00 per month	75.00
1 man at $80.00 per month	80.00
1 man at $100.00 per month	100.00
Total	$1,065.00

Or $35.50 per day.

Cost of Labor, Thirty-First Street.

6 men at $55.00	$330.00
1 man at $75.00	75.00
1 man at $100.00	100.00
Total	$505.00

Or $16.83 per day.

Cost of superintendence reckoned at $2.75 per day per station.

Cost of Lubricating Oil and Waste, Power-House No. 1.

Cylinder oil, 126 gallons per month, at 50 cents	$63.00
Engine oil, 94½ gallons per month, at 25 cents	23 62
500 lbs waste at 10 cents	50.00
Total	$136.62

Or $4.55 per day.

Cost of Lubricating Oil and Waste at Thirty-first Street, if all Engines Were in Use.

Cylinder oil, 63 gallons	$31.50
Engine oil, 60 gallons	12.00
Crank-case oil, 378 gallons	56.70
Waste, 200 lbs	20.00
Total	$120.20

Or $4.00 per day.

Total Cost per Day of 21 *Hours* 30 *Minutes, at Power House No.* 1*—Car Mileage,* 17,118.

Fuel oil for 1,203 H. P. at rate of 25.4 lbs. water per horse-power per hour from and at 212 degs., and 14.48 lbs. water from and at 212 degs. per lb. oil	7,258 gals.
Cost at $0.0257 per gallon	$186.53
Interest on machinery	17.58
Interest on real-estate and buildings	5.59
Depreciation of machinery	29.30
Lubricating oil and waste	4.55
Labor	35.50
Superintendence	2.75
Cost per car mile, Power House No. 1, for fuel oil, labor, lubricating oil, waste and superintendence	$.013333
Cost per car mile for interest and depreciation.	.003065

Total Cost per Car Mile, Power-House No. 1, $0.16398.

NOTE.—This includes, as it should, 4 5 lbs. per horse-power per hour for condenser engines, pumps, atomizing oil, etc.

Total Cost per Day of 21 *Hours* 30 *Minutes, at Thirty-first Street, if Car Mileage Were* 17,118.

Fuel-oil for 1,173 H.P., at rate of 33 28 lbs. water per horse-power per hour	9,200 gals.
Cost at $0.0257 per gallon	$236.55
Interest on machinery	10.11
Interest on real-estate	5.59
Depreciation of machinery	16.88
Lubricating oil and waste	4.02
Labor	16.83
Superintendence	2.75
Cost per car mile, Thirty-first Street Station, for fuel, oil, labor, lubricating oil and waste, and superintendence	$0 01513
Cost per car mile for interest and depreciation.	0.00190
Total cost per car mile, Thirty-first Street	0.01703
Percentage in favor of concentrated power	3 2-10 p. c.

In this comparison of concentrated and subdivided power it has been our object to put both plants on the same basis as far as it is proper, and to make the result depend on the real difference between the two. For these reasons the Thirty-first Street plant has been treated as if it were covering the same mileage as the No. 1 plant, and that it required the same horse-power on the line to do it.

The result, as given above, shows very little difference in cost per car mile, and if the pressure at the engines were 140 lbs., as required by the contract for the engines, we estimate that at least 6 per cent. would be saved in steam, and, therefore, in fuel oil, which would bring the total cost per car mile down to $.01615 for the Westinghouse plant as compared with $.016398 for the No. 1 plant, or 1½ per cent. less.

In considering the relative adaptability of the two systems to street railway work it should be remembered that the subdivided system allows of the shutting down of one or more engines when not needed, as during the slack time in the forenoon, middle afternoon and evening. This would be felt in economy more when the plant was in full operation than under present conditions.

Another matter which cannot help affecting economy is the very rapid regulation of the smaller engines, thus adapting themselves more readily to variations in load than is possible with the engines of the Corliss type. In a regulation test, October 26, 1892, it was found that the governors on the Westinghouse engines were able to change from a very heavy load to a mere friction load within four revolutions, or one second of time.

(*Concluded.*)

World's Fair Notes.

Brush Electric Company's Exhibit.

The exhibit of the Brush Electric Company, which occupies a space near the southwest corner of the Electricity Building of the World's Fair, is one of the most comprehensive displays of electrical machinery to be found on the grounds. Included with the Brush exhibit is the Short and the Sperry Electric Railway Companies display of street railway apparatus. The space occupied by the machinery amounts to nearly 9,000 square feet, a portion of which is devoted to a small office that forms a very conspicuous object in this part of the building. It is of Greek architectural design and is used as an office and reception room by the representatives of the company.

As an exhibit the Brush Company have arranged a number of dynamos representing the various sizes and designs near the outer line of their space, the centre of which is occupied by racks of arc lamps and switchboards. A very interesting part of the exhibit is a collection of all machines which were built by the company in the first years of its existence and sold to various customers. Most of these machines have certificates attached, showing the date of sale and length of time in actual service. The illustration shown in the frontispiece is that part of the exhibit occupied by the switchboard which is used to distribute the currents to the various machines.

A New Arc Light Machine.

Said to Have 14 per cent. Greater Efficiency than Present Types.

The Westinghouse Electric and Manufacturing Company has perfected an arc-light dynamo which, it is claimed, is a great advance over anything heretofore made. It is a direct current machine, and is controlled automatically. It will be made in sizes up to 80 lights each, and is said to have shown an efficiency of 94 per cent. on actual tests.

On the Transmission of Electric Signals Through Space.

BY W. H. PREECE, F.R.S.[*]

In the year 1842, Henry showed how the disruptive discharge of a Leyden jar in an upper chamber of his house magnetized needles in a cellar 30 feet below.

The introduction of that beautifully sensitive instrument, the telephone, in 1877 made us acquainted with disturbances and influences between neighboring wires at a distance which surprised every one. Morse signals, cross talk, strange noises, impaired the efficiency of telephone working.

In 1884, telegrams sent to Bradford (England) in Morse characters from the General Post Office, London, through a gutta-percha covered copper wire in an underground iron pipe, buried in the street, were read upon an open telephone circuit consisting of an iron wire carried on poles on the housetops 80 feet away.

In 1885, Mr. Edison showed how it was possible to communicate with a moving train by utilizing the electrostatic influence between a circuit erected upon the poles on the side of a railway and a telephone circuit carried by the train.

In the same year, I made many experiments to determine whether the effects observed in England were due to electro-magnetic induction, and were quite independent of the earth; and also to find out how far the distance between the wires could be extended before this influence ceased to be evident.

With our ordinary telegraph working currents the region of disturbance reached a distance of 3,000 feet, while the effects were detected on parallel lines of telegraph 10¼ miles apart, between Durham and Darlington. Even between the East and the West coasts at the border, a distance of 40 miles, currents produced at Newcastle on the Jedburgh line were distinctly heard at Gretna on a parallel line. These later results, in the North of England, were vitiated by the presence of a large network of railway and other telegraphs between the two places, and as they may not have been due solely to direct electromagnetic induction through space, but to electrostatic effects between neighboring wires as well, I took a district in the West of England, between Gloucester and Bristol, along the banks of the River Severn, where for a length of 14 miles, and at an average distance apart of 4.5 miles, no intermediate disturbing conductors existed between the pole lines. The Valley of the Mersey, and several other localities in England where no disturbing elements existed, were similarly investigated.

It is necessary at the outset to point out that if we have two parallel conductors separated from each other by a finite space, and each forming part of a separate and distinct circuit, either wholly metallic or partly completed by the earth, and called respectively the *primary* and the *secondary* circuit, we may obtain currents in the secondary circuit either by conduction or by induction, and we may classify them into those due to—

1. Earth currents.
2. Electrostatic induction.
3. Electro-magnetic induction.

It is very important to eliminate (1), which is a case of conduction, from (2) and (3), which are cases of induction.

1. EARTH CURRENTS.

When a linear conductor dips at each end into the earth, with which it makes a good connection, and voltage is impressed upon it by any means, the resulting return current would probably flow through the earth in a straight line between these two points if the conduction of the earth were perfect; but as the earth, *per se*, is a very poor conductor indeed (and probably is a conductor only because it is moist), lines of currents flow spread about symmetrically in a way that recalls the figure of a magnetic field. These diffused return earth conduction currents are evident at great distances.

These lines of current-flow are very easily traceable by means of exploring earth plates or rods. The primary current is best produced by alternating currents of such a frequency as to excite a distinct musical note on a telephone, and if these currents rise and fall periodically and automatically they produce an unmistakable wail. If they are made and broken by a Morse key they can transmit readable signals. The secondary circuit, which contains the receiving telephone, is completed in the case of the earth by driving two rods into the ground, or, in the case of water, by plates dipping into the water at a distance of from five to ten yards apart.

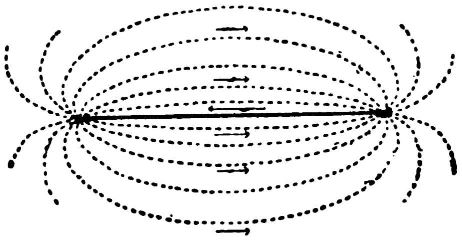

FIG. 1.

In this way the town moor near Newcastle, the sands and the land about Lavernock and Penarth, on the coast of South Wales, the water of the Bristol Channel, the towns of Liverpool and Leeds, and London itself, have been thoroughly explored; and it has been proved that the distance to which these lines of flow can be detected depends upon the intensity of the primary current flowing, on the area of the surfaces in contact with the earth, on the resistance of the portion of the earth utilized, and on the dryness of the season. In London the currents working the City and South London Electric Railway affect recording galvanometers at Greenwich, 4½ miles away, and a diagram of the train service on the railway can be recorded in any part of the metropolitan area.

FIG. 2.

The distance in sea water is not so extensive, for the latter is a better conductor than earth; still, with primary currents of 15 amperes, effects have been traced to one-third of a mile.

In all cases where disturbances have been created by electric tramways they have been shown to be greater in summer than in winter.

FIG. 3.

It is very necessary to be able to distinguish or separate these earth currents from currents due to induction, for they are very apt to give false effects and to lead to erroneous conclusions. This is easily done, if the instrument be sensitive enough, by making the primary current continuous when the earth current also becomes continuous, while induction currents are momentary and are observed only during the rapid rise or fall of the inducing cause.

ELECTROSTATIC INDUCTION.

When a body, A (Fig. 2), is electrified by any means and isolated in a dielectric, it establishes an electric field about it. Lines of electric force are projected from it in every direction; and if in the direction of any of these lines of force there is placed another similar body, B, it is also electrified by induction. If B be placed in connection with earth, or with a condenser, or with any large body, then the charge of the same sign as A is conveyed away, and B (Fig. 3) remains electrified in the opposite sense to A, and to the same amount A and B are seats of electric force. They form a stress, and are the ends of a line of force. The dielectric between them is displaced or polarized electrically. It is in a state of strain and remains so as long as A remains charged, but if A be discharged, or have its charge reversed or varied, then similar changes occur in B and through the dielectric separating them.

If A (Fig. 4) be a flat disc electrified positively and be placed inside a ring, B, then the ring becomes the termination of lines of electric force, and the sum of their terminal negative charges is equal to the whole positive charge of A. A may, in each of the above cases, be the section of a continuous wire or conductor forming part of a complete circuit. The charge on A may be due to the electric force of a primary current, while in the secondary conductor, B, the displaced charge in flowing to earth establishes a momentary current whose direction and duration depend on the current of A and on its rate of variation.

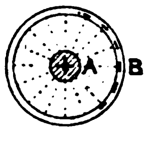

FIG. 4.

The strained state of the dielectric and the charges on A and B remain quiescent as long as the current flows steadily; but if the primary current ceases or falls, then we have the secondary currents in each conductor, as shown by the arrows, and flowing until equilibrium is restored.

The secondary currents, due to discharge, flow in opposite directions at each end, and there is always some intermediate zero point.

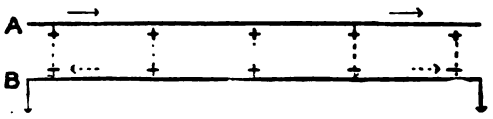

FIG. 5. DURING CHARGE.

It is thus easy in long circuits by observing their direction to differentiate currents of induction due to electric displacement from those due to electro-magnetic disturbance.

The dielectric plays just as important a part in the electrical operations that occur as do the conductors. Its molecular disturbance cannot be neglected. It is subject to strain and variations of displacement in one direction, while it is permeated by a wave of energy in another direction, viz., in the direction of the primary current. In fact, it is a question much discussed at the present day whether the prime action in all current effects is not this wave or flux of energy passing longitudinally through the dielectric in the direction of its length, and that nothing whatever passes through the conductors, which are mere passive agents in the matter, wasting energy but not transmitting it.

There are two views of the formation and support of a current. The one following Faraday regards it as the continuous discharge of the continuous charged molecules of the conductor, the action originating in and being propagated uniformly throughout the conductor. The dielectric plays only a secondary part. The other, derived from Maxwell by Poynting, regards a current as the consequence of the propagation of a wave of electrical energy through the dielectric in the direction of the line and which reaches the wire from the exterior. The conductor plays a secondary part; it simply dissipates the energy conveyed by the dielectric. The current is set up on the surface, and it penetrates the interior comparatively slowly, while its distribution in any given sectional area of the conductor is not uniform.

---

[*] Paper read at the International Electrical Congress, Chicago.

The truth lies probably in a combination of each view. The dielectric is as much an essential agent in the action as the conductor, and in each plane perpendicular to the current the charge and discharge of contiguous molecules, the formation of an electric field, the formation of a magnetic field, the flow of energy across this plane and parallel to the conductor, its dissipation as heat in the conductor, are all simultaneous and self-dependent, and equally concerned in the final result.

In a complete metallic loop, like a telephone circuit, the energy is propagated in the dielectric between the wires; it is dissipated in the wires; there are longitudinal waves propagated through the dielectric parallel to the wires, and there are other circular electro-magnetic waves emanating from each conductor as a centre and flowing as a resultant in planes perpendicular to the wires. Thus there are lines of electric force, lines of magnetic force, and lines of energy-flow. The first determine displacement, and are controlled by electrostatic capacity; the second determine electro-magnetic disturbance, and are controlled by inductance; the third determine transformation of energy, and are controlled by resistance. Time enters into the consideration of the longitudinal flow of the energy through the system, of the electro-magnetic disturbance through the dielectric at right angles to this flow, of the rise and fall of the current at each point of the circuit, of the character of the current at each point of the circuit, of the character of the current, whether continuous or alternating, and, if alternating, of the frequency of the complete alternations.

The effects of electrostatic induction do not play an important part in the inquiry immediately before us, but they are of great consequence in considering questions of speed of signalling in submarine cables and clearness of speech in long distance telephony.

(To be continued.)

New Beacon Lamp at 44 Broad.

The General Electric Company is magnanimously doing a fine piece of gratuitous advertising for the new incandescent lamp that has recently been put on the market by The Beacon Vacuum Pump and Electrical Company. As if conscious that other processes than those of actions at law must be followed to secure the supremacy of the Edison lamp, the officials of the General Electric Company have adopted this method of comparing their own with other lamps' and a number of "New Beacon" lamps have been placed on service in the chief offices of the General Electric Company at 44 Broad street.

We believe that not so much to enjoy the superior brilliancy of this new lamp as for comparison with Edison lamps were these "New Beacons" installed. Be that as it may, amusement has been caused by this unwonted action on the part of the Trust, as it displays unmistakably the serious straits to which that gigantic concern has been reduced for an argument against the new Beacon lamp. Were it possible to suppose for a moment that, in attempting such a comparison or contrast, the General Electric Company would act in a fair and unbiassed manner—a thing that has never yet been known to be done under any circumstances since the Trust was organized, the makers of the "New Beacon" would have no fear of the results; and even with sinister efforts being made to discredit the new lamp, nothing but benefit can accrue to the manufacturers for the publicity thus given their new lamp. The Beacon Vacuum Pump and Electrical Company is feeling grateful almost beyond expression for the splendid advertising its new lamp is receiving from its quondam opponent, the General Electric Company.

Charcot and His Fruitful Labors.

The death, at Morvan, France, of Jean Martin Charcot, which has lately been announced, recalls the significance of his labors in the new field of electro-therapeutics, and the extent to which the world is indebted to the French physician and scientist for his earnest recognition and upholding of the value of electricity in medicine. It is unquestionably much to these labors, and to the enthusiasm and conscientious work of those who took their inspiration from them, that the marvellous possibilities that are now opening out in the most merciful and efficacious method of alleviating and curing disease that the world has known are due.

Dr. W. J. Morton, who is deservedly recognized as the leader of electro-therapeutic development in this country, was for some time a student with Charcot, and on being asked by a representative of ELECTRICITY for some details of the character and work of his illustrious master, he said:

"In the death of Charcot the medical profession of the world has met with an irreparable loss. His was a unique, one might say an isolated character, in the sense that he combined both the true scientific spirit of hard work ever conducted on a pathological basis, i. e., upon postmortem findings, together with the happiest facility for culling, systematizing and popularizing the results of his labors. In this sense, I may truly say, he was most remarkable, and ranks with such men as Virchow and Pasteur. Enthusiastic by temperament, he never allowed his enthusiasm to get the better of his reason. Keen to detect isolated and hitherto unobserved medical anomalies, he never rode a hobby, but viewed his single facts in a grand correlation with all knowledge. His character was so broad and generous that he gathered about him special workers in all directions of medicine, stimulated them individually to special research, imbued them with his own confidence and methods of labor, and finally, so to speak, aided their combined labors so that the entire medical world got the crystallized benefit of their aggregate toil. By these methods he created what can only be regarded as a school of medicine, for the results of his work are as peculiar y stamped with the impress of his character as they are everlasting. His published works constitute a small library in themselves, and cover a very wide range of subjects.

JEAN MARTIN CHARCOT.

"The time that I spent at the Salpétrière in Paris. listening to Professor Charcot's lectures, I now look back to as the most instructive and delightful experience that has occurred to me in a medical life. I returned to America full of these new ideas, as well as of a vast amount of clinical and pathological instruction in the class of nervous diseases. I gave many demonstrations to physicians, illustrating the Charcot methods, hypotheses and facts of mesmerism, and introduced into this country the use of statical electricity."

Dr. Morton was here asked what were likely to be the developments in this country in the near future on the foundations thus laid by Charcot. He replied: "Well, we shall soon see some wonderful developments, although our progress has been comparatively slow. Like all pioneers, I found the conservatism of set barriers difficult to move. To push these ideas was like sticking a lance into the mud; the hole was no sooner made than it filled up again. To-day I have the inestimable privilege that all may have who in the beginning, knowing they are right, persist, of seeing both hypnotism and static electricity fully and cordially recognized. You ask me regarding Charcot's relations to the advancement of electro-therapeutics. I can only say that his mind was singularly alert to therapeutic measures, medicinal, mechanical and electrical. His great desire was to cure diseases. You know it has been said of many very scientific physicians that their interest in a case was confined to a diagnosis and a postmortem. It was, however, not so with Charcot; he took not only scientific but also a humane and practical interest in suffering humanity. So far as electricity goes, the world owes to him the introduction of static electricity into general practice. His experiments, to me, formed a nucleus about which has accumulated ideas of practice not yet fully fledged, and yet which I believe must, in time, in the hands of an advancingly educated profession, grow into a system and method of treatment of a large class of diseases, especially chronic diseases, superior to any we now possess. Static electricity is essentially high frequency, high potential current. For me such currents have ever possessed a fascination. They represent not the old-fashioned chemical decomposition of the continuous current, but represent energy acting intermittently. It is this sort of energy, whether in its electric forms or manifestations or in other forms of vibration, that is charged with an influence over the constituent parts of our human bodies which is mechanical rather than medicinal. In medicine, thus far, I have only heard or read in books of the conductive circuit or the inductive circuit, both of which may be measured in terms of Ohm's Law; but I intend to call attention, in future, in a more extended manner to the action upon human tissues due to the electric stresses, strains and displacements of known conductive tissues; namely, of dielectrics. This involves the construction of the electrostatic field. This is a field established between two charged bodies—every surge or wave in one or the other of these charged bodies produces an equal surge or wave in the intervening electrostatic field, and every dielectric or known conductor within this field is displaced, disturbed or strained synchronously with the initial disturbance. Now this initial disturbance may be in the shape of a spark drawn from the patient sitting on an insulated platform; may be set up by the discharge rods, with the patient in the same position; may be obtained from the electrostatic qualities of induction coils, with condensers in circuit, or in many ways where the electrostatic qualities of electricity are called into play intermittingly. This is a widely different effect from anything to be obtained by current strength in amperes, by magnetic lines of force, from electro and permanent magnets, or from the magnetic field of coils. Each nerve fibre of the human body, together with its connecting cell, constitutes an individual entity. Its sheath and structural framework is dielectric. Each cell, each muscle fibre, each gland cell, is more or less of the same homogeneous type. Conceive of the vast electrical shimmer or thrill to which such tissues are subjected from the electrostatic surges, and you may conceive, as I do, of a system of electro-therapeutics till now unknown and undescribed.

"In one sense, Charcot builded better than he knew when experimentally he had the courage to revivify statical electricity, for in doing so he has furnished others of us a hint to pursue the high frequency, high potential currents to further and legitimate limits. I believe, as I have just pointed out to you, that they will in the end, prove to be of incalculable value to mankind."

Personal.

Mr. W. H. Hall is to have charge of the electrical department which has been added to the course at the Baltimore Polytechnic Institute, formerly the Baltimore Manual Training School.

Mr. W. Oswald, general manager of the Southern Electrical Manufacturing and Supply Company of New Orleans, passed through New York last week on his return from a four months' trip abroad.

Mr. H. M. Littell, president of the Crescent City and New Orleans and Lake Electric Railway lines of New Orleans, is a visitor in New York.

Electricity in Mining.*

BY F. O. BLACKWELL.

It is roughly estimated that some three hundred companies in the United States engaged in mining and the kindred arts now employ electricity in their operations. As all these plants have been installed within the last few years, it is evident that mining engineers have been quick to appreciate the great advantage of the use of electricity and adopt it for their many requirements. In underground workings the chance of accident resulting in loss of life and destruction of property is, at the best, great. Humanity and economy both demand that any means that will secure greater safety should be eagerly grasped. It is an established fact that to add to the comfort and facilitate the work of the miner is to diminish financial risk and increase profits.

Electricity tried under the arduous conditions of mining service has been shown to be peculiarly efficient, safe and reliable. It presents a system of the greatest simplicity, completeness and flexibility, permitting power from one source to be distributed in units of any desired size and for any purpose to the places where it can be employed to the greatest advantage, thereby securing the minimum consumption of power and expenditure of labor. With electricity there is neither friction, heat nor condensation. There is no leakage nor loss of power when not in use, which especially recommends it for intermittent work. It is not affected by heat or cold, and does not vitiate the air, as is the case with steam and compressed air. The rapid deterioration of timbering, a source of great expense in all mines, due to bad air and heat, is to a great extent obviated. It has been urged against electricity that it increased the risk of fire. As a matter of fact it greatly decreases it, as the statistics of insurance companies testify. With proper safety devices and a system of concentric wiring it is practically impossible to start a fire from the current. To the engineer accustomed to speed indicators, pressure gauges and indicator cards, electrical methods of measurement seem particularly simple. The work being done by motor or generator at any instant can be read directly from a scale and, if desired, automatically recorded. If necessary motors can be controlled from a distance without difficulty.

The prime source of power is first to be considered. By conversion into electrical energy, water power, even at a considerable distance from the mine or mill, can be made valuable for all purposes, and steam power can be so located as to secure fuel and water cheaply. In addition to this, one large engine costs less, is more evenly loaded, requires less attendance, and is necessarily more efficient than a number of small ones. The introduction of electricity has in this way made important reductions in the cost of power, and there are cases in which it would be impossible to run without its help. An example is furnished by the Virginius Mine at Ouray, Col.; 300 horse power is carried at 800 volts from a water power four miles distant. The cost of coal at the mine was formerly $18 per ton, which would amount, for the present plant, to about $80,000 per year, equaling the total cost of the electric plant. The item of fuel was a complete saving, the expense of operating the steam and electric plant being about the same in other respects. Several mines in Colorado are operated by electricity that could not be by steam on account of their situation on the face of precipitous cliffs, up which the transportation of water and fuel would be nearly impossible. The character of the country over which the power had to be carried for the Virginius plant is exceedingly rough. A portion is at an elevation of 12,700 feet above sea level and well above the snow line.

ELECTRIC POWER TRANSMISSION AND DISTRIBUTION.

The cost of copper with any fixed loss, power and distance varies inversely as the square of the voltage. It is, therefore, evident that as high a voltage as possible should be used if economy of copper alone is to be considered. When the power is carried over long distances the cost of copper is the largest item of expense. For general distribution, especially underground convenience of insulation and handling are of more importance and call for a low potential. Nearly all the plants now in operation are supplied with current at 220 or 500 volts. There are a number, however, in which voltages of 1,000 and over are in use; notably at the Poorman, Comstock, and Calumet and Hecla mines. When bare wires are used, as for haulage, we are limited to a potential of 500 volts. Direct current generators are confined, by difficulties of construction, to potentials of less than 1,500 volts. The distance over which direct current can be economically carried at this potential is about four miles. Above this point alternating currents are used.

Alternating currents are particularly desirable on account of the ease with which the electrical pressure can be changed. By means of transformers without moving parts the high potential used for transmission is converted into low pressure for distribution. Alternating generators are wound for as high as 5,000 volts, but it will probably be found better to limit them to 2,500 volts. This potential permits of economical transmission to a distance of seven or eight miles. Above that distance step-up and step-down transformers are used. At present we do not care to go above 10,000 volts, which places the limit of about twenty-five miles to practical work. Alternating current motors possess nearly the same properties as those built for direct current. They have the advantage of being commutatorless, but can not be so heavily overloaded as a series wound direct current motor. They are, therefore, not as suitable for railway or hoisting service. Direct current can, however, be readily obtained from alternating by means of a rotary transformer which is a combined alternating motor and direct current generator. Motors have been designed to meet all the special requirements of mining work, and I will give a short description of some of the more recent applications.

ELECTRIC DRILLING.

Although it has been a matter of great difficulty to make an electric percussion drill which would stand the continual abuse and hard usage to which air drills are subjected, they are at present in constant and successful operation. By care in designing the coils so as to make them fire-proof and rigid they have been made to stand the strain. The drill consists of an outer iron pipe casing inside of and attached to which are two coils and the ratchet mechanism. The plunger, equipped with the ordinary chuck and rifle nut, is in the centre of the coils. The coils are supplied with current alternately and draw the plunger up and down at a speed fixed by the generator which supplies the current.

Electric diamond drills are in use for drilling solid holes and for removing cores for prospecting purposes. For prospecting both above and under ground the electric drill is particularly available, as it is extremely light and compact, and temporary wires can be run to places where it would be difficult to carry steam pipes or boilers.

ELECTRIC COAL CUTTING.

Electric coal cutters are now largely in use in the bituminous mines. In the machine most employed the coal is undercut by means of bits set in a rotary bar on the end of a sliding frame which is fed into the face of the seam. Other cutters are constructed with a sprocket chain to the links of which are affixed cutting tools. Machines of this kind can be fed either in or along the face of the coal for long wall or room working. In both of these the electric motor is built into and forms part of the frame, adding but little to its weight. In exceedingly hard or pyritiferous coals, which can not be cut with a continuously moving cutter, an electric pick machine is advantageously used. This also has the advantage of giving a kerving wider at the front than at the back of the cut, which allows the coal to fall outward and more lump coal to be gained. The motor draws a projectile back against a spring and releasing it lets the pick fly against the face of the coal at the rate of 150 blows a minute. Electric drills for putting in holes, for blowing down coal after it has been undercut or from the solid, as is done in anthracite, are also used. Mounted on a column a machine of this kind is free to drill in any direction from horizontal to vertical. A drill of this type, of 100 pounds' weight, will easily drill a $1\frac{1}{2}$-inch hole at the rate of six feet per minute in hard or soft coal.

VENTILATING.

It is often desirable in order to obtain the best results from fans and blowers to locate them at the most distant points from the surface. This is done more easily by electricity than by any other power, and the blowers can be readily advanced as the workings are pushed deeper. The electric motor is especially suitable for high-speed blowers, which are efficient and occupy but small space. Much saving in piping can also be effected by using higher velocities and forcing air out from the inside rather than sucking it from the surface. Fans can be controlled by a shutter on the outlet pipe or the speed of the motor may be varied.

ELECTRIC LIGHTING.

It has been found that much more work can be gotten from men by giving them better illumination. By avoiding the use of oil lamps and candles the air is left purer, and both time and power saved by doing work underground which would otherwise have to be done on the surface. Electric lighting also reduces the risk of accident by calling attention to conditions which would otherwise pass unnoticed. In gaseous mines, where many explosions have resulted from the reckless use of miners' lamps, electric lighting is invaluable.

METALLURGY.

It is impossible to go fully into the electro-metallurgical and electro chemical processes now in use. The refining of black and blister copper has reached large proportions, fully one-third of the copper refined in this country being electrically treated, and considerable quantities being shipped abroad. By this process gold and silver are obtained from the matte, the recovery of which would be impracticable by any other method. Gold, silver and lead are also beginning to be refined electrolytically. Aluminum and silicon are gotten almost exclusively by electric smelting and reducing. Caustic soda, sodium, chloride of lime and vermilion are commercially obtained by electrolysis.

I have not, within the scope of this paper, been able to deal with all the many and constantly increasing applications of electricity, but enough has been said to make evident its far-reaching importance to the mining industry.

---

* Abstract of paper read before the International Engineering Congress at Chicago.

Current Items.

A movement is on foot in Cincinnati to organize a society to be called the Cincinnati Electrical Society. City Electrician Cabot, Thomas Creighead, of the Creighead Engineering Company, and Thomas F. Cohesey, of the Commercial Telegraph Company, are pushing the project. The object of the organization will be advanced discussion of the science of electricity in all its branches.

Professor Weston, in answer to the question how the trouble arising from the action of electric currents on water pipes can be prevented, is reported to have said: "In one way only, if a single trolley line continues to be used with the earth in circuit, and that is by insulating the pipes in some moisture proof material. With a double trolley road, that is with two wires above the car and two trolleys, there would be none of this trouble."

To obviate the blinding effect of the direct rays of searchlights on the pilots of vessels passing through the Suez Canal, the canal authorities have issued an order making it obligatory after October 1 next, on all vessels passing through the canal by night, to employ an apparatus for dividing the light of the projector into two divergent rays. Approaching vessels may, by this means, travel right up to each other without their respective helmsmen being blinded. The diverging apparatus which is to be used has been devised by one of the agents of the company.

Canadian Electrical Association.

The Third Convention of the Canadian Electrical Association will be held at Toronto, September 12, 13 and 14. The following papers will be read:

"Some of the Causes of Interruption to Telegraph Circuits," Mr. Fred. C. Robertson, Toronto.

"Water Wheels," Mr. A. C. McCallum, of Peterboro.

"The History of the Telephone in Canada," Mr. L. B. McFarlane, of Montreal.

"Electrical Education," Mr. E. B. Merrill, Toronto.

"Direct Connected Dynamos and Steam Engines," Mr. John Langton, Toronto.

"Electric Street Railways," Mr. E. Carl Breithaupt, of Berlin.

On Thursday, the 14th, the delegates will enjoy a special excursion to Niagara, and will take a ride on the new electric road.

General News.

What is Going on in the Electrical World.

Muskegon, Mich.—The Shaw Electric Crane Company will hereafter manufacture the dynamos to sell with its cranes.

Asbury Park, N. J.—The new Asbury Park and Belmar electric railway has been completed as far south as Shark River.

Plainfield, N. J.—The Plainfield Electric Street Railway Company is now planning to extend its line to Netherwood.

Hagerstown, Md.—The Schuyler Electric Light Company has added a 75 H. P. engine to its plant, and will extend its service.

Belmar, N. J.—The electric light system on Ocean avenue has been completed, and arc lights now illuminate the thoroughfare.

Seattle.—An ordinance has been introduced providing for the construction of a subway and the placing of all wires underground.

Hastings, Neb.—Owing to difficulties with the local lighting company, the town is considering the feasibility of putting in a plant of its own.

Brooklyn, N. Y.—Experiments are being made on the Atlantic Avenue line with a view to having the entire system equipped with air brakes.

Toledo, O.—The city council is still wrestling with the municipal plant problem, and has received many tenders for supplying the needed apparatus.

Franklin, Pa.—The boiler in the electric light station exploded on the 21st, killing one man, and wrecking the entire building and machinery; loss $25,000.

Mauch Chunk, Pa.—The electric railway system is completed, the poles and wires are up, and ready for business, connecting the three sections of the town.

Elwood, Ind.—The Elwood Electric Street Railway Company is contemplating an extension of its lines to Alexandria via Orestes. The distance is ten miles.

Franklinville, N. Y.—The electric lights were turned on here on Friday night for the first time. Everything worked smoothly, far beyond the expectation of the company.

Cincinnati.—Messrs. A. J. Baker, D. J. Hauss, Oliver Kinsey, W. H. Jones and E. A. Sarran have been appointed a committee on by-laws for the proposed electrical exchange.

Paw Paw, Mich.—The town has sold $15,000 of electric light bonds to an Adrian bank and will build its own plant. Water power has already been purchased for that purpose.

Providence, R. I.—Arbitrators have agreed upon 38½ cents per night for each arc light for street purposes furnished for this city by the Narragansett Electric Light Company.

Indianapolis, Ind.—The Citizens' Street Railway Company announces that it will put in service on the week of the National G. A. R Encampment twenty-five new motor cars.

North Attleboro, Mass.—The Attleboro Electric Light and Power Company will build a plant here. The building is to be 55 x 77. The plans were drawn by Loring & Phipps of Boston.

Auburn, N. Y.—The common council has appropriated $25,000 to be paid to the Auburn Electric Light Company for lighting the city for one year—the full amount of the company's offer.

Rochester.—The Glen Haven narrow gauge steam road, running to the lake, has so far proved a failure, owing to the heavy grades, and the company will be compelled to adopt the trolley.

Mobile, Ala.—The Mobile Street Railway Company has formally opened its electric line, the cars are painted in white and gold, and are very striking. Mr. Raphael Semmes is the general manager.

Wilmington, Del.—The projectors of the New Castle and Wilmington Electric Railway will begin its construction at an early day. Application has been made to the New Castle council for permission to lay tracks in the streets.

Yarmouth, Me.—The lighting plant, which has been in process of construction for three months, has been completed, and the town is lighted by electricity for the first time. Messrs. Loring & Gould did the construction work.

Saline, Mich.—A franchise is to be had by any company that will construct an electric railroad from Adrian to Ann Arbor and take in intermediate towns. The franchise is for 30 years and stipulates that a power-house shall be built at Saline.

St. Joseph, Mo.—The city electrician will hereafter be compelled to fill an exhaustive monthly report covering every pound of material used and every dollar spent on the light plant, so that it can be quickly told just what the operating expenses are.

Longmont, Colo.—The Colorado Electric Light Association at its annual meeting at Colorado Springs elected J. J. Elliott, of Idaho Springs, president; M. T. Moreland, of Golden, vice-president, and C. M. McCamer, of Longmont, secretary and treasurer.

Niagara Falls.—The Cataract Construction Company has begun work on an underground conduit for conveying electric cables from the wheel-pit to the site of the proposed plant of the Pittsburg Reduction Company, the construction of which is to be begun soon.

Kingston, N. Y.—The Colonial City Electric Railway Company, which has asked for a franchise, has offered to give its note for $10,000 as a guarantee that the road shall be completed within a year. Messrs. Wendell Goodwin and Frederick Swift are the leading men interested in the company.

Noblesville, Ind.—The scheme for connecting a dozen Indiana towns with Indianapolis and Chicago by an electric line has collapsed, and the two promoters, E. J. Pennington and N. D. Pontious have fled, after obtaining perhaps $5,000.

Dubuque, Ia.—There is a little war between the Dubuque Light and Traction Company and the Star Electric Company, and the employees of the former company are threatened with arrest for cutting down the poles which either has the right to use.

New York.—The Broadway Cable Company has made application for permission to lay signal wires in its conduits to be used for signalling the power houses in case of accidents. The Third Avenue Railroad Company made a similar application a year ago which has not been granted.

Detroit.—The Public Lighting Commission has awarded the contract for the electric light conduit system to Liphardt & Winterhalter, the lowest bidders, and work will soon be commenced. The St. Clair Tunnel Company is considering the advisability of adopting electricity as a motive power in the tunnel.

Portland, Me.—At the recent annual meeting of the Bradbury-Stone Electric Storage Company it was decided to purchase the property and rights of the sub-companies at Kittery, Me., East St. Louis, Ill., and Sioux City, Iowa.—The Bath electric line has been formally opened, and cars are now running regularly.

Boone, Ia.—After a year and a half without electric lights of any kind, Boone is now rejoicing over the completion of the best built electric plant in the State, operating both arc and incandescent lights. The company has a power-house amply large, and expects to supply the power for five miles of electric road which it will soon build.

Annapolis.—Foundations have been laid at the Naval Academy for the new power-house. When it is completed eight boilers will be put in, and three boilers will supply steam-power now utilized at the Academy in heating the public and private buildings. These dynamos will be placed in the building to supply light and power through the grounds.

Binghamton, N. Y.—The trustees of the State Hospital have decided to advertise for bids on the following proposals: "First, to furnish a complete electric lighting plant on the river bank; second, to equip a complete plant on the asylum grounds; third to supply the necessary power from the city's plant, and fourth for wiring the State Hospital buildings for electric lighting purposes."

Removal.

The offices of the Star Electric Lamp Company and the Sunbeam Electric Lamp Company have been removed from the Chamber of Commerce Building, Chicago, to No. 102 Michigan avenue.

Boston Notes.

Captain W. Brophy, the well-known electrical and insurance expert of this city, has raised a small cyclone about his distinguished personality by reason of an utterance of his made on Wednesday last at a meeting of the National Association of Fire Engineers in Milwaukee, when, in reference to the recent serious conflagrations in Boston he assigned the cause of them to over-insurance. Insurance men, property owners and some of the morning papers warmly resent such an insinuation. Be that as it may, Captain Brophy was never yet known to deliver an opinion upon anything with which he was not familiar and capable of substantiating, and if Captain Brophy has been correctly reported, we don't doubt but he could prove his statement if necessary.

To check, if possible, the growing public distrust in the General Electric Company, some one, presumably in the employ of the Trust, industriously causes to appear about every third day in the Boston and Lynn papers, in both of which cities there are thousands of stockholders, reports stating that there is not the slightest ground for alarm in what is being done by the directors. The company is declared most emphatically to be as sound as ever, and that all statements to the contrary are baseless. It is admitted that a large part of the working force has been laid off and the rest is working short time, but this has been done as a simple matter of economy in view of the general financial and commercial depression that prevails. These frequent assertions about the company's financial strength and stability, however, don't appear to answer the purpose they were intended to serve, for they simply keep men's tongues wagging, their shoulders shrugging and their eyes casting furtive glances down the legal and financial columns of the daily papers, as if they were expecting to hear something drop.

The Safety Electric Light Company, whose office is at 620 Atlantic avenue, Boston, making a specialty of lighting railway cars by means of current generated in a primary battery of its own exclusive type, is running a car between Boston and Chicago over the Fitchburg Railway. Besides lighting the car, a number of ventilating fans are operated by the same current, and the entire system is reported as being a success.

Notwithstanding the very general depression now prevailing, there are several electrical factories in Boston which are not only running full time but even increasing their staff. This is indeed subject for congratulation, and during the present week there have not been lacking indications that a somewhat easier feeling prevails both in financial and business circles; and the opinion is growing that the bottom has been reached.

The Island of Malta Wants a Lighting Plant.

From the United States *Consular Reports* for August we learn that the establishment of an electric lighting plant for the cities of Valletta and Floriana, on the Island of Malta, is under consideration.

Mr. W. H. Preece, who is now in this country, first called the attention of the Governor to the matter and drew the specifications. American manufacturers will do well to look into the matter. The Colonial Government will guarantee payment. Mr. John Worthington is the U. S. Consul at Malta, and will supply further information.

A large contract for a plant on the Island of Manilla has recently been secured by American concerns. The New York Insulated Wire Company sold the wire, the Brush Company the dynamos, and the Ball Engine Company the engines.

Portable Electro-Hydrogen Lighter.

A very ingenious piece of apparatus is the electro-hydrogen lighter described and illustrated below. The operation of the device will be readily understood by reference to the accompanying illustrations in connection with the general description given herewith.

The object of this electric lighter is to provide a small temporary light for cigar lighting and for other igniting purposes, domestic use, etc., and the device is made in a compact and very neat form, convenient for easy handling.

Fig. 1 gives a general external view of the lighter, from which it will be seen that the apparatus is ornamental in design as well as useful. It is a radical departure from other electric gas lighters in its construction. The outside jar is really a battery cell, which contains dilute sulphuric acid (one part of sulphuric acid to six parts of water and two ounces of bichromate of potash) as shown in the cross-sectional view in Fig. 2. The carbon electrode of the battery is shown at *E*, Fig. 2, and the zinc at *J*. The zinc is attached at the end of the gas tube *G*, the whole being placed within a gas tight vessel with its opening at the lower end and placed in the liquid after the manner of a porous cup. The tube *G* terminates at its upper end in a gas tip, and at *H* is a small hole which allows the accumulated gas within the inverted cup to escape into the upper part of the tube.

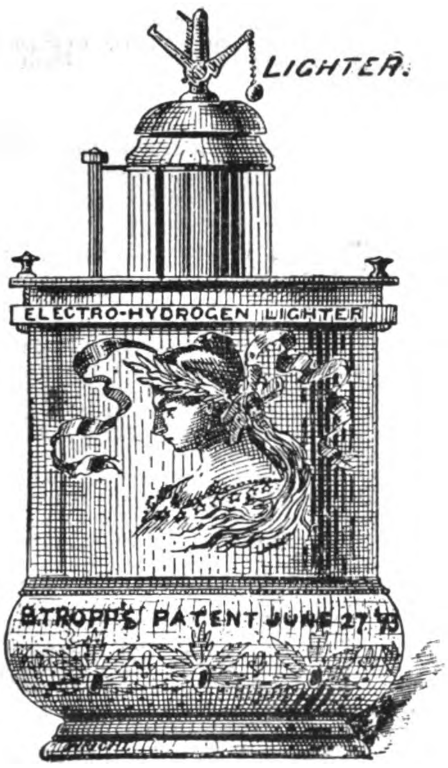

FIG. 1.

On the outside of the jar, on top, but suitably enclosed, is a spark coil, *F* (Fig. 2), one terminal of which is connected to the carbon electrode in the battery; the other terminal is connected with the contact pin *L*, which is insulated from the gas tube, to which it is attached at *M*. The lever *P*, being in metallic contact with the gas tube, causes an electric spark to be generated when it is pressed down by the finger plate *P*, and contact is made with the contact pin *L*, and by the same movement the gas cock is opened, allowing the gas to issue from the small hole *K*, at the top of the tube.

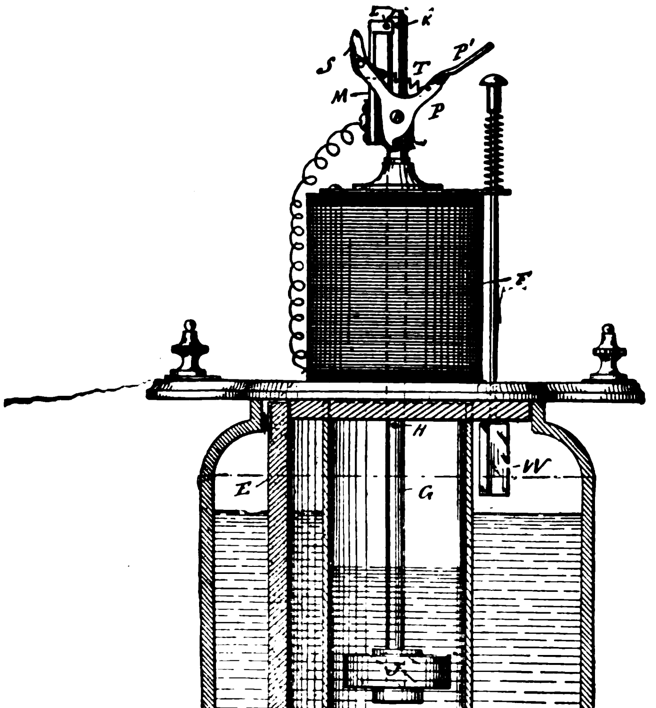

FIG. 2.

This device is very useful and ornamental in the household, smoking room, cigar stores, offices, steamers, yachts, smoking cars, and in all places where a temporary light is required.

This invention has recently been patented by Mr. B. Tropp, 101 East 90th street, New York City.

The "New Beacon" Goes in Spite of Hard Times.

The Beacon Vacuum Pump and Electrical Company, which last week made formal announcement that the "New Beacon" was ready for shipment in any quantities, have no reason to cry "Hard Times." Orders have come in in flattering numbers, and from all parts of the country. The "New Beacon" is a sure winner.

George Cutter.

George Cutter is pleased with his growing sales of Simplex wires, having just furnished another large batch for the Ferris Wheel.

A New Carbon Company.

After many months of preparation and experimenting, the Boulton Carbon Manufacturing Company of North Tonawanda, N. Y., is ready for business. The officers of the company are Wm. H. Boulton, late of Cleveland, president: Geo. P. Smith, secretary; J. H. Schmeck, treasurer.

The company occupies three buildings, one 50 by 120 feet, and two 40 by 150 feet each. The product at present is 18,000 per day, and thirty hands are employed. The output will soon be increased to 60,000 per day.

The Bryant Specialties.

The Bryant Electric Company of Bridgeport, Conn., believes in perpetual push, whether general business is bad or good. By this the company shows wisdom, and will maintain its position at the front. The new catalogue of the Bryant Company shows that their line of specialties has been increased by nearly a score. They are all necessities, and the high-standard of excellence which has always distinguished "Bryant" goods will be maintained.

Micanite is in the Swim.

The Mica Insulator Company has just issued a 4-page circular containing, besides a description of the specialties they manufacture, a number of very strong testimonials on Micanite from the leading manufacturers of electrical machinery.

Micanite is fast being recognized as a first-class insulator in every respect. This company has pased the experimental stage, and is sending out an insulator made of pure sheet mica that cannot be equalled by anything now on the market. They will be most happy to refer any one to the different companies who have adopted Micanite as an insulator.

Hart Switches.

The Hart & Hegeman Manufacturing Company, of Hartford, Conn., send out a neatly printed catalogue of Hart Switches, for which the following points of merit are enumerated:

The Hart Snap Switches are mounted on porcelain only.

The movement is rotary in one direction by quarter turns, keeping the contacts bright and free from dust, and giving the maximum length of "Break."

"Make" and "Break" are instantaneous, the switch-plates remaining stationary and locked until the handle has been given a quarter turn and the actuating spring has its maximum tension.

The actuating spring is of the best steel wire, and as it is not in circuit its temper cannot be affected by the current.

The current passes from one contact to the opposite contact, through solid metal and not through pivoted joints.

The "Break" is double in all sizes, and in the double-pole switches the circuit is broken at four points.

The insulation used is of the best quality obtainable.

The workmanship and carrying capacity of every switch is guaranteed.

All switch covers are finished in polished nickel unless otherwise ordered.

Further information will be furnished upon application to the company.

INCORPORATIONS.

Atwood Electric Head Light Company, St. Louis, Mo.—to manufacture electric lamps, etc. Capital stock, $125,000. Promoters: L. C. Atwood, E. B. Roth, M. Keber, all of St. Louis, Mo.

The Youngstown Park and Falls Street Railway Company, Youngstown, Ohio—to operate street railway, steam, electric, horse or other motive power to be used, etc. Capital stock, $50,000. Promoters: H. G. Hamilton, M. T. Evans, J. H. McEwen, Geo. A. Baker, Jas. Hiney.

Iowa Electric and Construction Company, Des Moines, Iowa—to do a general electrical and supply and construction business. Capital stock, $100,000. Promoters: A. T. Hess, J. A. Innes, Josiah Stedman, E. C. Spinney, E. G. Pratt, Wm. Bowen, Des Moines, Iowa.

The Mildwood Electric Light, Heat and Power Company of Kings County, Flatbush, N. Y.—to furnish electricity for lighting, heating and power purposes in the town of Flatbush. Capital stock, $50,000. Directors: William Matthews, of Brooklyn; A. J. Ditmas, John Z. Lott, John D. Prince, Jr., of Flatbush, and others.

The Electric Service Company, a new telegraph company, which will build and operate lines in New Jersey only. Capital stock, $50,000, one-third paid in. The incorporators are Winfield Thomson, Charles N. Cadding and George W. Peck, all of Westfield, N. J.

The Altmeyer Electric Light, Heat and Power Company, McKeesport, Pa. Capital stock, $30,000. Directors: George Altmeyer, George J. F. Falkenstine, John Oliver, Jacob P. Hill, F. W. Patterson, Theodore Tonnele, Peter Milmoe, Frank Becker, John F. Davitt, William J. Kirk and Frank J. Chester.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUG. 1, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

502,297. Electric Locomotive. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Electric Car Company of America, same place. Filed Nov. 30, 1886.

502,530. Electric-Railway Trolley Base. Otto Rau, Jersey City, N. J., assignor of one-half to Robert S. Dobbie, New York, N. Y. Filed Oct. 31, 1891.

502,538. Converter System for Electric Railways. Georg W. von Siemens, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Mar. 29, 1893. Patented in Austria-Hungary Aug. 7, 1886, Nos. 31,923 and 2,522, and Nos. 570,681 and 2,394, and in England Aug. 26, 1886, No. 10,926.

502,539. Electric Railway System. Georg W. von Siemens, Berlin, Germany, assignor to Siemens & Halske, same place. Filed March 29, 1893. Patented in Austria-Hungary Aug. 7, 1886, Nos. 31,923 and 2,522 and Nos. 570,681 and 2,394, and in England Aug. 26, 1886, No. 10,926.

502,553. Trolley-Head. Robert S. Dobbie, Jersey City, N. J., assignor of one-half to Otto Rau, Milwaukee, Wis. Filed Oct. 31, 1891.

502,629. Trolley-Guard. George Moore, Boston, Mass. Filed Aug. 22, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

502,278. Carbon-Holder for Arc Lamps. Sigmund Bergmann, New York, N. Y. Filed Oct. 22, 1892.

502,322. Electric Incandescent Lamp. Paul Scharf, Vienna, Austria-Hungary. Filed April 17, 1893.

502,340. Rheostat. James J. Wood, Fort Wayne, Ind. Filed July 15, 1892,

502,444. Electric Regulator. Daniel M. Moore, New York, N. Y. Filed Nov. 8, 1892.

502,458. Lamp-Guard. Emil Gahlau, Detroit, Mich. Filed Nov. 18, 1892.

502,465. Means for Protecting the Carbon-Holders of Electric-Arc Lamps. Jacob F. Mehren, Chicago, Ill. Filed Oct. 6, 1892.

502,471. Electric-Arc Lamp. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 4, 1891.

502,518. Automatic Cut-Out. Carl Hoffman, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 11, 1893.

502,519. Two-Pole Switch. Carl Hoffman, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 11, 1893.

502,535. Circuit-Controlling Mechanism for Arc Lamps. Charles E. Scribner, Chicago., Ill., assignor to the Western Electric Company, same place. Filed July 26, 1890.

502,655 Socket for Incandescent Electric Lamps. Waldo C. Bryant, Bridgeport, Conn., assignor to the Bryant Electric Company, same place. Filed May 6, 1893.

502,682. Distribution of Alternating Electric Currents. Wilhelm von Siemens, Berlin, Germany, assignor to Siemens & Halske, same place. Filed July 16, 1892. Patented in Austria-Hungary Dec. 28, 1885, Nos. 768 and 36.918 and 17,243 and 20.890; in England Dec. 30, 1885, No. 16,088; in Belgium July 15, 1886, No 73, 585, in France Oct. 20, 1886, No. 176,794; in Italy Dec. 30, 1886, Nos. 20.191 and 381: in Germany Jan. 14, 1887, No. 38,880: in Sweden April 15, 1887, No. 814, and in Norway June 30, 1887, No. 51.

502,687. Arc-Lamp Frame. August Weber, Schenectady, N. Y. Filed Sept. 8, 1892.

DYNAMOS, MOTORS, ETC.

502,377. Electric Motor or Dynamo. Samuel Paugh, Indianapolis, Ind. Filed Oct. 11, 1892.

502,384. Dynamo-Electric Machine or Motor. Harris J. Ryan, Ithaca, N. Y. Filed Sept. 7, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

502,398. Portable Telephone. Brown S. Flanders, Boston, Mass. Filed Jan. 31, 1891.

502,466. Telephone Circuit and Apparatus. James L. McQuarrie, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed May 25, 1893.

502,472. Electric Annunciator. Theodore Spencer, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Feb. 7, 1893.

502,660. Electric Switchboard-Signal. Francis W. Dunbar, New York, N. Y., assignor to the American Telephone and Telegraph Company, of New York. Filed May 15, 1893.

MISCELLANEOUS.

502,272. System of Electric Distribution. Edward M. Bentley, Boston, Mass., assignor to the General Electric Company, same place. Filed May 8, 1893.

502.287. Electrical Cash Register, Recorder and Indicator. Leo Ehrlich, St Louis, Mo., assignor, by mesne assignments, to the National Cash Register Company, Dayton, Ohio. Filed Sept. 28, 1889.

502,300. Electric Pole Changer. Charles. E. Kells, Jr., New Orleans, La. Filed Feb. 23, 1893.

502,315. Electrical Indicator for Elevators. Eugene E. Peirce, Boston, Mass. Filed July 5, 1892.

502,325. Electric Jail. Charles H. Sparks, St. Louis, Mo., Filed March 28, 1892.

502,358. Electric Cable. Theodore Guilleaume, Cologne, Germany. Filed March 1, 1893.

502,381. Electric Synchronizer for Clocks. Henry Prentiss, Elizabeth, N. J. Filed May 19, 1892.

502,399. Electric Telemeter. Charles H. Haskins, New York, N. Y. Filed March 9, 1892.

502,405. Galvanic Battery. Edward H. Lyon, Brooklyn, N. Y. Filed Sept. 26, 1892.

502,454. Method of and Apparatus for Measuring Electricity. Aloar Aberg, Helsingfors, Finland. Filed Jan. 10, 1893.

502,494. Electrical Heater. Charles E. Jones, Elgin, Ill. Filed Aug. 1, 1891.

502,624. Electric Water-Wheel Regulator. Eugene R. Holcomb, Portland, Ore. Filed Jan. 21, 1893.

502,626. Electric Signal Apparatus. Jacob W. Lattig, Easton, Pa. Filed June 14, 1893.

502,627. Railway-Track Electric Annunciator. Jacob W. Lattig, Easton, Pa. Filed June 14, 1893.

502,670. Magneto-Electric Machine. Frank X. Hofbauer, Newark, N. J. Filed Oct. 22, 1892.

502,677. Insulator. Louis McCarthy, Boston, Mass. Filed Sept. 23, 1892.

ELECTRICITY.

VOL. V. NEW YORK. SEPTEMBER 6, 1893. CHICAGO. No. 8

A Novel Method of Transforming Alternating Into Continuous Currents.

BY CH. POLLAK.[*]

It is well known that the use of accumulators in central stations has taken a great development in Europe during the last years. Indeed, nearly all the *central plants* in Germany, France and England generating *direct currents* are now provided in the central station itself, or in sub-stations, with storage batteries of comparatively large size working in parallel with the dynamos while the load is at its maximum and supplying the whole current needed in the time of low demand. The technical journals having given ample information about this subject, I desired to show you on this occasion the projections of several central stations which we built in Germany; unfortunately they were not ready at my departure, and as our mails are not yet run by electricity they arrived only yesterday. The photographs represent batteries of accumulators for 110 volts and our types of 600 and 1,200 amperhours in central stations built by Lhneckert & Company of Nuremberg, and by the Society of Electric Lighting in Frankfort-on-Main.

The alternating current light stations storage batteries have also proved of great usefulness for exciting the magnetic field of generators, the latter giving in these cases far better results as to production of constant tension and regular light than with excitation by means of direct current dynamos. But it has not been possible as yet to secure for alternating machinery a reserve to be disposed of at any time for the supply of current equal to the ever-ready storage battery in the direct system, nor to combine with an alternating system substations duly situated and possessing all the advantages of the direct system, including the supply of currrent for electro-chemical work and ordinary motors. (Another field for the employment of stationary accumulators has begun to open in electric railway plants.) The surplus current necessary in the moments of starting or for overcoming steep grades is now in many cases supplied by storage batteries placed either in the generating station or near the points of increased demand for current. Owing to the lack of appropriate alternate current motors this sort of current has not yet got any significance for electric railways, though it might give many advantages, especially on as long lines as are now built anywhere, by applying high tension primaries and line transformers. If there were a simple means for directly feeding from transformer substations on the line the usual continuous current motors and charging auxiliary storage batteries, with or without capacity, a great saving in conducting material and a remarkable increase in safety and simplicity of working would be the result.

All these considerations have led me to the construction of an apparatus for directly transforming alternating into direct currents that requires little cost, little space and little attendance, and gives high economical results. I call this transformation *direct* in contradistinction to the well-known method of using a dynamotor consisting of an alternate current motor and a direct current generator on the same axis.

An ordinary commutator held in motion synchronous with an alternating current generator gives birth to a pulsating current of the same direction whose tension varies between zero and a certain maximum given by the generator; it will therefore not be able to drive direct current motors or produce electrolytical effects; to fulfil these purposes, the tension of the pulsating current is to remain above a certain minimum determined by the counter-electromotive force to be overcome in the performance of an electrical work. Herefrom I have drawn the following principles for the construction of the commutator.

The typical commutator of this kind consists of two ranges of insulated strips alternately connected with the generator. The width of the insulation between the strips is in a definite proportion to the width of the strips, which proportion is made adjustable so that the brushes of the commutator will take off only that part of the current whose tension has the proper value.

If now, for instance, an accumulator battery is to be charged, I will first adjust the proportion between the width of the strips and of their intervals in such a way that the tension of the pulsating current to be taken off by the brushes and led to the battery may not drop beneath the amount of the counter-electromotive force of the accumulators and the latter be avoided from discharging in the generator circuit. Herefrom I will finish the adjustment of the commutator by a definite displacement of the brushes in order to produce the interruptions of the pulsatory current in those moments when its tension is equal to the counter-electromotive force of the battery in charge, and so does away with sparking.

In my first apparatus for laboratory purposes, the commutator fixed on the prolonged axis of a small synchronous alternating current motor consisted of two sliding rings insulated from each other, and which the alternating current is led to by brushes, and two ranges of strips with converging edges alternately connected to the sliding rings. The brushes sliding on the surface of the strips can be displaced in the ordinary way round the axis and parallel to it. The combination of these two movements allows to fix the necessary minimum tension of the pulsatory current as well as the sparkless taking off of this current in those moments when its tension is equal to the counter-electromotive force, and consequently its intensity zero.

Later on I left the pointed strips in the apparatus for practical use. The edges of the strips are made parallel to the axis, and the two ranges of strips fit to be displaced against each other by turning them separately round the axis; besides there are take-off brushes in double number whose distance can also be varied. By combining these two movements I may succeed without any difficulty in quickly attempting the appropriate position as to tension and sparkless working. In this shape the device is cheap, occupies but a small space, without foundations, and requires little attendance in comparison with a transformer dynamo of the same output. As to attendance in charging accumulators, for instance, the adjustment will have to be changed successively at the beginning of a charge during about a quarter of an hour, according to the then rapid increase of the tension; then nearly no attention has to be given the commutator, the tension rising at a very low rate until the end of the charge with approach and the voltage rise faster necessitating new adjustment of the intervals and brushes. The whole attendance therefore is very simple and takes little time and effort. To reduce the attendance I shall provide the new machines with automatic brush regulators. The first apparatus was built for 80 amperes and has proved to perform the transformation with nearly no loss at all. The measurements have been executed in the following manner: The alternating current was passed through a down-step transformer, and the secondary first through a fluid resistance and then through the commutator and battery to be charged. In both cases the number of watts in the primary and secondary circuits of the transformer were measured by means of a wattmeter. The output in the first case was 82,770; in the second 82,670. The motor having only to overcome the friction of the brushes requires only from 80 to 100 watts with full load, or less than 190 of the whole energy passing through the commutator.

(The small efficiency of only 82 per cent. of the transformers will be explained, as I had at my disposal only transformers of older style.)

---

[*] Paper read at the International Electrical Congress, Chicago.

It might be said that a pulsatory current as produced by this commutation was perhaps not good for charging accumulators, but in my experience I did not find any difficulty with it. It may be true that grid or other oxide pasted plates will not stand it, owing to insufficient contact between grid and active mass; in every case the Planté type pure lead plates are preferable for the purpose. (The accumulators used in my experience were of my own system). They have pure lead plates or electrodes, produced by electrolytically depositing porous lead on laminated lead plates, provided with large conducting surface; this artificial increase of surface is effected by previously passing the lead bands through specially designed rollers that impart to them a great number of pins and ribs. When ready for use the plates are most solid and may be thrown or bent without harm, the porous lead adhering so fast to the core that no more exact limit is existing between them. Moreover the plates are arranged in the cells in such a way as to grant them free extension in either direction by suspending each plate separately on two glass tubes. The charging of these accumulators by means of the alternating current commutators, as described above, performs in quite like manner and in no more time than with the ordinary direct current. Indeed the bubbles of hydrogen and oxygen gas escaping at the end of the charge being usually small, with pure lead plates, seem to be of still less size when commutated current is employed, and give the fluid quite a milky appearance; herefrom it may be inferred that the destructive effects the bubbles sometimes produce upon the porous surface layers by mechanical action in cases of over-charging or excessive charging intensity are of lower influence on the durability of the plates than even the common direct current.

On the Transmission of Electric Signals Through Space.—II.

BY W. H. PREECE, F.R.S.[*]

3. ELECTRO-MAGNETIC INDUCTION.

Magnetic force is that which produces or tends to produce polarization in magnetizable matter, viz., iron, nickel and cobalt, and electro-magnetic disturbance in non-magnetizable matter and the ether. It excites lines of magnetic force and becomes a stress. An electric current in a conductor is a seat of magnetic force. It establishes in its neighborhood a magnetic field.

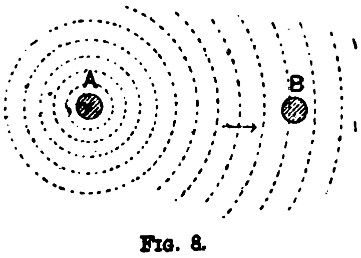

FIG. 8.

The lines of force [Fig. 8] in such a field are equivalent to circles in a plane perpendicular to the direction of the current, which, during the rise of the current in A flow outwards, and during the fall of the current flow inwards, like the waves on the surface of smooth water when a stone is dropped into it, but moving with the speed of light. Thus any other linear conductor B, placed in this field parallel to A, is cut at right angles to itself by these lines of force—in one direction as the current rises, and in the other direction as the current falls. The projection of lines of magnetic force through a linear conductor in a direction perpendicular to its length excites electric force in that conductor; and, if the conductor be continuous and form part of a circuit, it establishes voltage, and therefore a current in this secondary circuit. Now, the strength of this secondary current, depends on the strength of the primary current, on the rate at which it rises or falls on the resistance of the secondary circuit, on the distance which separates the two circuits, and on the length of the inductive system. The direction of the secondary current everywhere is reverse to that of the primary during its rise and in the same direction during its fall.

If the two circuits are separate and independent, this action between them is called mutual induction; but if B be a part of the same circuit, A, it is called self-induction. The amount of induction is dependent also on the magnetic conditions present in the conductors and in the space between them. This is measurable in its own unit [which it is proposed to call "henry"], is called *inductance*, and usually indicated by S or M, according as the question dealt with is self or mutual induction.

EXPERIMENTAL INVESTIGATION.

Since 1885 I have had a vast number of experiments made to thresh out the laws and conditions that determine the distance at which these magnetic disturbances can be usefully evident. The instrument used to receive these signals has been generally the telephone, but many absolute measurements have been made with a very sensitive reflecting galvanometer. The judgment required to determine the relative intensity of sound in a telephone is a very variable and uncertain agent, even though many observers be utilized and the same experimenters perform with the same apparatus. But this does not apply to the observation of the limiting audible intensity of signals. The point where sound ceases is obtained with concordant and satisfactory results when the mean judgment of several observers using the same telephone is made use of. I never use less than three observers, and sometimes have employed as many as seven. By this means we observe by what I call the average normal ear.

I. To prove that the effects were due to Electro-magnetic Induction.

Conductors of copper wire insulated with gutta-percha were formed into quarter-mile squares [Fig. 9] and laid on a level plain at a distance of a quarter of a mile apart.

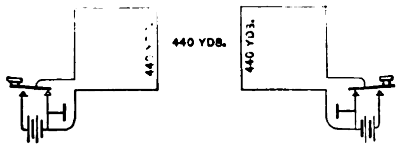

FIG. 9.

Arrangements were made for sending vibratory or alternating currents which could be broken into Morse signals by means of a telegraph key. Telephones were used as receivers, which transformed these signals into buzzing dots and dashes.

On closing the circuit in one square and sending signals, conversation could be readily held between the two operators by means of the Morse code. Now, obviously, earth conduction could play no part in this transmission of signals, for the squares were insulated throughout from the earth.

Next, in order to ascertain to what extent, if any, electrostatic effects were observable, one pole of the battery used was put to earth, and the further end of each square was disconnected [Fig. 10].

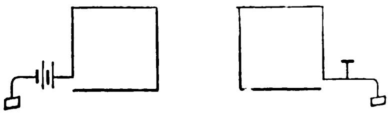

FIG. 10.

Now, by this arrangement, the mean electric force of one square was doubled, as compared with the former experiment, where the circuit was completed, but no effect was observed in the second square, either in the receiving telephone or with the reflecting galvanometer. The squares were even superposed at a distance of only 15 feet apart, the upper one being suspended on poles and the lower one lying on the ground, but without any result. Hence the effects observed in this experiment were clearly due to electro-magnetic induction.

II. To prove that the effects increased directly with the strength of the primary current used and diminished with the resistance of the secondary current.

a. Two quarter mile squares of insulated wire were opposed to one another, and the distances between the front faces varied from 8 yards to 192. Currents of one and two amperes respectively were sent into one square, and the induced effect in the second square with two amperes was invariably twice that with one ampere. The measurements were made with a reflecting galvanometer.

b. Open wires were placed parallel to one another, and a mile apart horizontally (Fig. 11). The primary circuit was two miles long. The other, the secondary circuit, was divided into two equal one-mile lengths. With a primary current of .22 ampere the vibrations were just audible in a telephone fixed to either of the single mile lengths of the secondary, the total resistance in the latter circuit being 85 ohms. With a similar current (.22 ampere) in the primary and the secondaries joined into a two-mile length, the same limit of audibility was reached when the resistance in the secondary was doubled, that is, it was raised to 170 ohms. Next, the current in the primary was doubled or increased to .44 ampere; and with a one-mile secondary the total resistance had to be doubled in order to reach the same limit. Finally, when the current in the primary was raised to .88 ampere—four times the original figure—then the same limit was reached when the resistance was quadrupled.

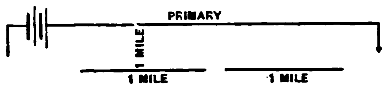

FIG. 11

III. To find how the effects varied with the length of the inductive system, and with the distance separating them.

The law for variation of length and distance is very complicated, and depends wholly on the form of the circuit and its various reactions. It may be briefly summarized as follows, but the experiments upon which these conclusions are drawn will be given as an appendix, together with the equations developed from them.

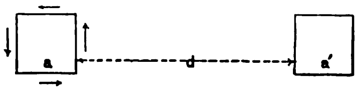

FIG. 12.

Let l = length and d = distance apart of two conductors assumed equal and similar, then

a. With two infinitely long straight wires, it varies inversely as d alone.

b. With one infinitely long straight wire and a wire of finite length, it varies as $\frac{l}{d}$.

c. With one infinitely long straight wire opposed to a rectangle, the law becomes

$$\frac{l}{\varphi}\left(\frac{l}{d}-\frac{l}{D}\right),$$

where D is the distance from the face to the back of the rectangle.

d. Where the rectangle is replaced by a square, the above formula becomes

$$\frac{l^2}{\varphi\, d\,(l+d)}$$

e. With a rectilinear wire of finite length l opposed to a square, the length of the former being equal to the face of the latter, it varies as

---

[*] Paper read at the International Electrical Congress, Chicago.

$$\frac{l}{d},$$

f. With two squares of equal dimensions opposed to one another [Fig. 13], the effect varies, where l is great compared with d, as

$$\frac{l}{\sqrt{d}};$$

but when d exceeds half l, it varies as

$$\frac{l}{d}.$$

NOTE.—With cases *c*, *d*, *e* and *f*, if d became very great, the effect would diminish and ultimately disappear, owing to the opposing current in the back of the square having practically the same influence as that in the front. When d is very great the effects due to a and a_1 may be neglected.

g. With two rectilinear wires of equal length if the effect of the magnetic waves due to the return current through the earth be neglected, then when l is great compared with d it varies as

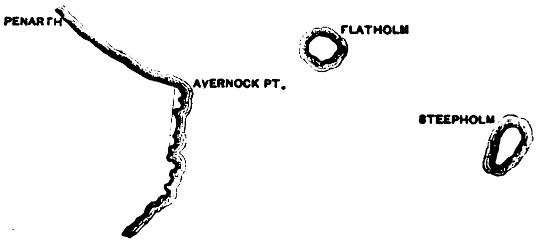

FIG. 13.

$$\frac{l}{d};$$

but when d is great compared with l, it varies as

$$\frac{l^2}{d^2};$$

The complete formula for the aerial portion of the circuit is as follows:

Let c_1 = current through primary.
q_2 = quantity induced in secondary.
r_2 = resistance of secondary.
l = length of either wire.
d = distance between wires.

Then M being a constant in C. G. S. units,

$$q_2 = \frac{c_1}{r_2} \frac{\sqrt{l^2 + d^2} - d}{d} \times \text{M}.$$

The complete formula must of course allow for the reverse effect of the return circuit through the earth. I hope later to obtain sufficient data on which to base such a formula.

The value of M, obtained from a series of experiments on two parallel squares of wire, 1,200 yards in length and 5 yards apart, was found to be .003.

h. The difference in water as compared with air is not very marked. In certain experiments on the Conway Estuary which were considered reliable, and which appear on Table I, it was about 6 per cent. more in the air than in water. The result was probably due to the magnetic waves being degraded into electrical currents in traversing the conducting sea water.

4. PRACTICAL EXPERIMENTS.

The Bristol Channel proved a very convenient locality to test the practicability of communicating across a distance of three and five miles without any intermediate conductors. Two islands, the Flat Holm and the Steep Holm, lie off Penarth and Lavernock Point, near Cardiff, the former having a lighthouse upon it. On the shore two copper wires, weighing 400 lbs. per mile, combined in one circuit, were suspended on poles for a distance of 1,267 yards, the circuit being completed by the earth. On the sands at low water mark, 600 yards from this primary circuit and parallel to it, two ordinary gutta-percha covered copper wires and one bare copper wire were laid down, their ends being buried in the ground by means of bars driven in the sand.

One of the gutta-percha wires was lashed to an iron wire to represent a cable. These wires were periodically covered by the tide, which rises here at spring to 33 feet. On the Flat Holm, 3.1 miles away, another gutta-percha covered copper wire was laid for a length of 600 yards.

There was also a small steam launch having on board several lengths of gutta-percha covered wire. One end of such a wire, half a mile long, was attached to a small buoy, which acted as a kind of float to the end, keeping the wire suspended near the surface of the water as it was paid out while the launch slowly steamed ahead against the tide. Such a wire was paid out and picked up in several positions between the primary circuit and the islands.

TRANSMISSION OF ELECTRIC SIGNALS.

The apparatus used on shore was a 2 H. P. portable Marshall's steam engine. working a Pike & Harris alternator, sending 192 complete alternations per second, with a voltage of 150, and of any desirable strength up to a maximum of 15 amperes. These alternating currents were broken up into Morse signals by a suitable key. The signals received on the secondary circuits were read on a pair of telephones—the same instruments being used for all the experiments.

The object of the experiments was not only to test the practicability of signalling between the shore and the lighthouse, but to differentiate the effects due to earth conduction from those due to electro-magnetic induction, and to determine the effects in water.

I have already alluded to the way in which the lines of current-flow were mapped out. It was possible to trace without any difficulty the region where they ceased to be perceptible as earth currents and where they commenced to be solely due to electro-magnetic waves. This was found by allowing the paid-out cables, suspended near the surface of the water, to sink. Near the shore no difference was perceptible whether the cable was near the surface or lying on the bottom, but a point was reached, just over a mile away, where all sounds ceased as the cable sank but were recovered again when the cable came to the surface.

The total absence of sound in the submerged cable rather surprised me, and it leads to the conclusion, either that the electro-magnetic waves of energy are dissipated in the sea water, which is a conductor, or else that they are reflected away from the surface of the water like rays of light.

Experiments on the Conway Estuary, showing the relative transparency of air and water of these electro-magnetic waves, tend to support the latter deduction, for if much waste of energy took place in the water the difference would be more marked; it was 6 per cent. only. As it is we have ample evidence that the electro-magnetic waves are transmitted to considerable distances through water, though how far remains to be found.

There was no difficulty in communicating between the shore and Flat Holm. Messages were read. Mr. Gavey, who was making the experiment on the island, wrote me: "There was then somewhat a lengthened pause, due to a slight derangement of the machinery on the mainland, but at 2 P. M. I heard clearly and distinctly the following, 'Here, Haskayne' (one of his assistants), 'with a message from Mr. Preece for Mr. Gavey.'" I was in London that day. "Then followed the announcement of the sad and sudden death of Mr. Graves, which cast a gloom over the success of the experiment. It seemed an extraordinary fact that the first readable message transmitted for such a distance by such means should announce the death of the head of the Technical Department."

The distance between the two places was 3.1 miles. The attempt to speak between Lavernock and Steep Holm was not so successful. The distance was 5.35 miles, but though signals were perceptible, conversation was impossible. There was distinct evidence of sound, but it was impossible to differentiate the sounds into Morse signals. We were just on the limit of audibility, and we were using our maximum available power. If either line had been longer, or the primary currents stronger, we should have spoken as was done at Flat Holm.

The fact indicated by the formula for parallel wires, that the limiting distance increases directly with the square of the length of the circuits, has a very important bearing on the practical results of these experiments, for it shows that if we can make the length of the two lines long enough it would be easy to communicate across a river or a channel. Of course, as previously pointed out, the formula does not take into account the effects of the reverse magnetic waves generated by the return current through the earth, and at present no data exist on which a satisfactory calculation can be based; but, for example, there is little doubt that two wires ten miles long could signal through a distance of ten miles with ease.

Although communication across space has thus been proved to be practical in certain conditions, those conditions do not exist in the cases of isolated lighthouses and lightships, cases which it was specially desired to provide for. The length of the secondary must be considerable and for good effects at least equal to the distance separating the two conductors. Moreover, the apparatus to be used on each circuit is cumbrous and costly, and it may be more economical to lay an ordinary submarine cable.

Still, communication is possible even between England and France, across the Channel, and it may happen that between islands where the channels are rough and rugged, the bottom rocky, and the tides fierce, the system may be financially practical. It is, however, in time of war that it may become useful. It is possible to communicate with a beleaguered city either from the sea or on the land, or between armies separated by rivers, or even by enemies.

A use to which these electro-magnetic disturbances can be applied is to indicate to ships their contiguity to lighthouses and land falls. Experiments are being made in this direction by Mr. Stevenson, of the Northern Lights Commission, on the coast of Scotland, but no results have yet been published. He proposes to submerge a cable on a given fathom line through which special automatic distinguishing signals are being sent, so that a ship approaching or crossing this line can pick up these signals on board and learn her true position.

I have also pointed out that as these waves are transmitted by the ether they are independent of day or night, of fog or snow or rain, and therefore, if by any means a lighthouse can flash its indicating signals by electro-magnetic disturbances through space, ships could find out their positions in spite of darkness and of weather. Fog would lose one of its terrors, and electricity become a great life-saving agency.

APPENDIX.

I. Experiments to determine the electro-magnetic induction, both in water and air, between a rectangle and a finite line of length equal to the face of the rectangle, June–July, 1893.

Currents were sent through the rectilinear circuit, A, by means of a suitable key, and the in-

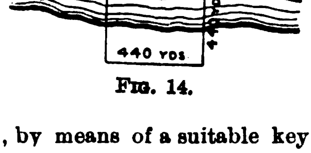

FIG. 14.

duced effect on the rectangle was observed on a carefully adjusted reflecting galvanometer.

COMMUNICATIONS.

Prof. Stine was not Correctly Reported.

Armour Institute,
Chicago, August 28, 1893.

To the Editor of Electricity.

Dear Sir :—In the issue of Electricity for August 23, 1893, a kind reference was made to the equipment and future work of the Electrical Department of Armour Institute in Chicago. In the extract from an interview recently published in the *Inter-Ocean*, the writer was represented to have conceded that European electrical apparatus was generally superior to that made in this country. This was a mis-quotation on the part of the reporter ; my own opinion is in reality opposed to this statement.

The equipment of the Electrical Department of Armour Institute will not only be very extensive, but will be peculiar to the extent to which American apparatus will be employed. It is with much pride that we have noted the rapid advances made by several American makers of apparatus, and we believe that in no other institution will the equipment be so thoroughly American. While the greater portion of laboratory apparatus will be of American manufacture, European makers will also contribute. This broad policy must result in good, educationally, and further, having the same style of apparatus from both American and foreign manufacturers'comparative tests can be made with best results.

It is not long since that a writer for one of the leading electrical papers stated that a really first-class reflecting galvanometer cannot be obtained from an American maker. This, in my opinion, is a mistake, and I shall endeavor in the near future to give my reasons for this statement.

Reference was also made in the same mistaken vein to the Weston instruments. I am very glad to state that Mr. Weston is now making the standards for the calibrating department of Armour Institute, and the Weston ammeters, voltmeters and wattmeters will be used throughout wide ranges as working standards in the laboratory. When the contracts for these instruments are all filled Armour Institute will, without doubt, have a larger equipment of Weston instruments than any similar institution.

Yours truly,
W. M. Stine,
Director of the Electricity Department.

Goliath was only a Bluffer.

An appreciative constituent in the State of Michigan writes as follows :

"You must accept my compliments for the manner in which you attack the Trust (open and above board), which fully illustrates your principle of fair play to all and monopoly to none, and I am inclined to think that the Goliath has met his David."

Nails in this Coffin.

(*From the Wall Street Daily News.*)

We are told by a gentleman high in the councils of the Ceneral Electric Company, and enjoying intimate relations with Drexel, Morgan & Company, and by us considered a high authority on the subject, that it is useless to look for any rally or improvement in the price of General Electric stock as long as Mr. Coffin remains President of the company. Mr. J. Pierpont Morgan has never forgiven Mr. Coffin for having sold out on him about a year ago, and since then he [Mr. Morgan] has taken but a lukewarm interest in the company. Our informant states Mr. Morgan will take no steps to force Mr. Coffin out, but will let the price of the stock and the money necessities of the company do it for him.

The Ansonia Electric Company.

Mr. F. S. Terry, manager of the Ansonia Electric Company, has sent out the following statement to the customers of the house:

"Owing to complications resulting from the present business depression, the affairs of this company have been placed in the hands of Mr. James B. Waller, assignee, permission having been obtained from the Court to continue the business. All amounts due us will now be payable to him. Plans are already under way for a speedy settlement of our difficulties, but much will depend upon the promptness with which we are able to collect our accounts. We trust we are not mistaken in believing that we have the well wishes of our customers, and that they will assist us by making prompt remittances."

The Blue-Print Steal.

Trials of Mead, Clarke and Hamilton Begun at Pittsburgh.

The electric conspiracy case was called in the Criminal Court at Pittsburgh on Monday, Sept. 4th, before Judge Collier. The court-room was crowded with spectators. The defendants now on trial are : Morris W. Mead, William J. Clarke and Milton H. Hamilton. The selection of the jury consumed less than one hour, and the three defendants present entered a plea of not guilty. D. F. Patterson made the opening address for the prosecution.

A full report of the proceedings will appear in Electricity next week.

THEY ALSO STEAL SIGNS.

Suit for $10,000 Damages Brought by The Western Electric Co. against The General Electric Co. in Chicago.

Suit has been brought in the Superior Court of Cook County, Ill., for $10,000 damages, by the Western Electric Company against the General Electric Company, and criminal proceedings will be instituted against certain employees of the latter company if they can be found.

Part of the exhibit of the Western Electric Company has been thirty arc light poles of an improved pattern, upon which they had been granted the privilege by Prof. Barrett of placing two signs, one near the base and one at the extreme top, above the lamps.

Part of these poles supported arc lamps of the General Electric Company's make, and Lieut. E. J. Spencer, in charge of the latter's exhibit, insisted that the signs of the Western Electric Company should be removed from these poles. Prof. Barrett declined to grant this request.

In despair of accomplishing his object by lawful means, Lieut. Spencer, so it is claimed, conspired with a number of his employees to remove the signs by stealth, and some time during the night of July 17 the signs were stolen by these employees, the official guards having been duly bribed.

Suit is now brought, as above stated, to recover damages from the General Electric Company, as the guilty parties have removed themselves, for the time being at least, from the reach of criminal prosecution.

Death of R. D. Nuttall.

Robert D. Nuttall, the well-known manufacturer, and founder of the concern of R. D. Nuttall & Company, died on August 29, at his home in Allegheny, of pneumonia.

The Electro-Therapeutic Assoociation.

Programme of the Chicago Meeting.

The third annual session of the American Electro-Therapeutic Association, to be held in Chicago on September 12, 13 and 14, is expected to reveal a marked advance in the science. A leading topic to be discussed is "What are the Possibilities of Electricity in the Treatment of Fibroid Growths?" Among those who will take part are: Dr. J. H. Kellogg, of Battle Creek, Mich.; Dr. Georges Apostili, of Paris, France; Dr. Georges Gautier, of Paris, France; Dr. La Lorre, of Rome, Italy; Dr. Augustin H. Goelet, of New York; Dr. A. Lapthorn Smith, of Montreal, Canada: Dr. Franklin H. Martin, of Chicago, Ill.; Dr. G. Betton Massey, of Philadelphia, Pa.; Dr. Margaret A. Cleaves, of New York; Dr. George F. Hulbert, of St. Louis, Mo.; Dr. E. L. H. McGinnes, of New York.

"The Influence of Frequency of Interruptions and Character of Induced Current Waves upon Physiological Effect" will also be discussed by Prof. W. J. Morton, M.D., of New York; M. le Prof. d'Arsonval, of Paris; M. le Dr. Larat, of Paris; M. G. Weisse, of Paris; Prof. du Rois-Raymond, of Berlin; Mr. Newman Lawrence, of London, Eng.; Mr. Jno. J. Carty, of New York; Prof. G. M. Hammond, of New York; Dr. W. F. Hutchinson, of Providence, R. I., Prof. Elihu Thomson, of Boston, Mass., besides many of those taking part in the former discussion.

Most of these physicians will read papers.

On the Carrying Capacity of Electric Cables, Submerged, Buried or Suspended in Air.—II.

BY A. E. KENNELLY.[*]

From the measurements made on the samples of buried cable the mean thermal resistivity of the sandy soil in which they rested was almost 50 units, or fifteen times less than the mean resistivity of the insulator.

Formula (4) modified to include the resistance of the ground becomes

$$C = \sqrt{\left(\frac{\theta}{\rho\ (S + G)}\right)} \quad . \quad . \quad (9$$

and with the safety limit of 25° C. here recommended for Siemens cable, (5) becomes

$$C = \frac{5}{\sqrt{\rho\,(S + G)}} \quad . \quad . \quad (10)$$

As an example, suppose the cable previously considered to be buried at an axial depth of 2′ 6″ (76.2 cms.) in a soil of resistivity 50. Here the depth in radii is 148.2 and reference to the preceding curve shows that the ground resistance per centimetre is 0.9 *g*, or in this instance, 45 units. The thermal resistance of the insulator having been found to be 81.36, the total thermal resistance in the heat current path is 126.36. Substituting this in the formula (5) or (10),

$$C = \frac{5}{\sqrt{126.36 \times 0.000009417}} = 144.9 \text{ amperes},$$

the computed drop in temperature within the cable will be

$$\frac{24 \times 81.36}{126.36} = 16.1^\circ \text{ C},$$

and the temperature elevation of the sheath 8.9° C.

INFLUENCE OF EXTERNAL LAYERS OF HEMP OR COMPOUND.

If the cable instead of being simply sheathed in lead has also, as is usually the case, additional coverings of jute or compound, with or without intermediate metal bands or wires, additional

J. F. CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 75, 920 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	$2.00
FOREIGN COUNTRIES, - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Electrical Frauds Condemned. The criticisms offered by ELECTRICITY upon the exhibits of several medical quacks which disgrace the Electricity Building at the World's Fair received a notable endorsement from no less an authority than Prof. S. P. Thompson in the course of his remarks at the collation of the Electrical Congress held in that building.

After bestowing the most liberal praise upon the exhibition of electrical work both in the Fair and throughout this country, Prof. Thompson stated that in one respect England had gone ahead of America, viz., in properly branding that class of parasites who trade upon the credulity or gullibility of the public by selling electric belts and electric plasters to cure any and every disease. Prof. Thompson also recited the recent exposure of a similar fraud, by the *Electrical Review*, of London, an account of which was published in ELECTRICITY, and scored the American electrical journals for their failure to perform their obvious duty in enlightening the public as to the true status of these humbugs.

We have emphatically stated several times that a number of these electro-therapeutic exhibits are a disgrace to the electrical department, and this disgrace was made still deeper by the attempt on the part of Mr. Hornsby, of this department, to defend these humbugs in reply to Prof. Thompson's remarks. It is to be regretted that these impostors, whose exhibits have no business in company with those of the reputable concerns which surround them in Electricity Building, have secured such a hold on one of the officials of this department, whose office it is to maintain the character of the exhibition untarnished, that he should feel the necessity of defending a class of swindlers whose knavery is condemned by every reputable electrician and physician.

This action is the more surprising coming from a physician, as Mr. Hornsby in his remarks mentioned that he had followed the study of medicine both in this country and abroad. It would be of interest to know what medical colleges sanction the indiscriminate use of electric belts and plasters, as physicians are usually the least tolerant of any class of men in regard to quackery and humbugs in their profession.

It is not to be supposed that the men who sell electric plasters and belts indiscriminately for the cure of forty or fifty different diseases are susceptible to feelings of embarrassment or shame, otherwise their presence during such a denunciation might have been productive of salutary effects.

Next to the officials who have permitted this class of exhibits to degrade the character of the Fair, the electrical journals have been most culpable in the neglect of their duty. With the exception of ELECTRICITY there is not one of them which has not, by its conspicuous silence on this subject, giving tacit sanction to a number of swindles which it would not dare to openly defend or advertise ; and if an electrical paper owes any duty to the public which it pretends to serve, that duty should certainly be to expose those impositions parading under the guise of electrical science.

In this respect ELECTRICITY stands alone, and among its contemporaries not one appears to be free to criticise even the most barefaced swindle which seeks shelter under the name of the science which it espouses.

……o……

Electrical Signalling Through Space. The paper of Mr. Preece on this subject read at the Chicago Electrical Congress presents a most instructive account of the experiments carried out in England, and points out pretty clearly the limitations which in practice attach to the plan of communicating intelligence by electricity without wires.

The experiments carried on under the direction of Mr. Preece across the British Channel were successful in the case of a distance of three miles, and less so in the attempt to cover five miles, but as the distance separating the parallel lines between which communication takes place is limited by the length of these lines, it is obvious that in practice this distance must be short, except in special cases. For this reason the system can be of no practical value in the case of lighthouses and ships, as the length of the lines carried on them is necessarily short. In the case of a vessel the maximum distance would therefore be the length of the ship, and this would be of no avail in case of danger.

Even in communicating across rivers, where the necessary length of line can be run on either bank, the system will generally be found of little value, as ordinarily a submerged cable furnishing direct communication will be found available and much more satisfactory.

The experiments are of scientific interest, however, from the fact that they showed that this phenomenon of transmission through space is due to electro-magnetic induction, and that there is actual transformation of the current into mechanical energy and back again into electrical energy, instead of simple conduction through the earth.

……o……

Incandescent Arc Lamps. The problem of producing a practical arc lamp with an enclosing chamber like that of the incandescent lamp is one that has received the attention of a number of inventors for many years back, and although several lamps of this character have been devised and patented, all of them up to the present have contained features which prevented their practical adoption, either on account of their low efficiency, short life or danger of explosion.

The appearance of such a lamp is rather that of a luminous globe than the concentrated light of an arc, and for this reason its use would be found advantageous in many places where a steady diffused light is needed. The results given by Mr. Marks in his paper, printed elsewhere, show that most of the difficulties inherent in this problem have been overcome, and the tests of the lamp described give promise of the production of a commercial article.

The two most important requisites are carbons perfectly free from impurities, and a quality of glass capable of withstanding the severe heat to which it is subjected. In the old attempts to produce these lamps the best quality of carbon attainable contained marked traces of metallic and other impurities, so that the negative pole of the arc received a mass of plastic deposit which extended across the arc, making it in reality an incandescent lamp.

The valve for the egress of the CO_2 in the bulb of such a lamp is also a matter of special moment, as the pressure of the enclosed gas must be maintained below a certain amount to avoid explosion. It was found expedient by experimenters on many of the early lamps of this type to conduct their observations and experiments from an adjoining room to that containing the lamps owing to the certainty of eventual explosion. Mr. Marks states, however, that after perfecting the valve used on his lamp there has not been an explosion or any trouble caused by the gas for a number of months.

The coating of the globes with the carbon deposit is considered by Mr. Marks to be a practical advantage, as the light is more evenly distributed and the luminosity appears to be greater than with cleaned globes. With pure carbons this deposit has been found to be but slight.

……o……

Western Electric vs. General Electric. It will surprise no one who has taken notice of the tactics pursued by Mr. E. J. Spencer, who is in charge of the General Electric Company's exhibit at the Fair, to learn that he has at last been caught in the commission of a crime.

The publicity given to this occurrence, some of the details of which are related elsewhere, should enable the trade to estimate Spencer correctly, and deprive him hereafter of the privilege of associating with gentlemen. He has proved himself a lawless fellow who is not to be further tolerated by law-abiding people.

Electricity has stated many times that employees of the General Electric Company are taught by the precept and example of the higher officials that roguery and rascality are virtues which will be rewarded, and it is not strange that Mr. Spencer has followed in the footsteps of his superiors.

Moreover, he went to the Fair in the first place with an exaggerated idea of his own importance, as also of that of his company. He seems still to believe that the General Electric Company owns the Fair, and that he is the chief executive officer, notwithstanding the many slaps in the face he has received in the past few months. Chicago is not so far from New York but that Spencer should have learned ere this that his company is dead, and that any further effort on his part to boom its apparatus at the Fair is useless.

Spencer's attempt to have the Westinghouse sign removed from the south wall of the building rendered him, it was supposed, sufficiently contemptible and ridiculous. He has now shown that he has no conception either of common fairness or of his own humiliating position.

He is an arrogant person, whose appointment to represent the General Electric Company at the Fair is added proof of the wretched management of that company.

Other manufacturers have made friendships at Chicago which will produce good business for them for many months to come; but Spencer and the General Electric Company have made nothing but enemies, of whom they had plenty before the Fair opened.

The Western Electric Company may be depended upon to carry its case through to the end.

……o……

The General Electric Wreck. The immediate movements of the General Electric wreck are as difficult to predict as it would be to tell in which direction the derelict at sea, floating bottom upwards, at the mercy of wind and wave, would be next impelled.

It is doubtful if any member of the Board of Directors has any clearly defined plan beyond the active use of the headsman's axe, cutting off heads and expenses as rapidly as possible.

From the point of view of competing manufacturers, who care more about the sale of their own goods than about the success or failure of the sham Trust, the position of the latter to-day leaves nothing to be desired. It has fallen down before the race was half run, and it will be thoroughly distanced before it can get on its feet again, besides being bruised and knee-sprung.

It is superfluous to say again that the Trust scheme has been a failure. But it will never be superfluous to keep before the public with persistent iteration the fact that it has been worse than a failure. In its greedy attempt to control the business, the Trust for many months was strong enough to do almost irreparable injury to many single concerns and to the trade at large.

The electrical trade would have suffered little harm from the present wave of depression which is passing over the business world had it not been for the blighting effects of the Trust on the business eight months ago. And but for the existence of the inflated trusts, like General Electric, Whiskey and Cordage, there would have been no such tremendous shrinkage from fictitious values, and no such consequent loss of confidence in the financial world.

While Electricity has the ear of the electrical trade, these facts will not be allowed to become obliterated or befogged.

The power of the press, when grounded upon TRUTH and JUSTICE, is exemplified in the twelvemonth fight Electricity has made against the Electric Trust scheme. The organization of the company was a blunder, its policy has been a series of blunders. Whatever the future of the General Electric Company may be, that once imperious organization is to-day an absolute wreck, without business, without money, and without friends; with no organization and with no ability within its own ranks to perfect an organization--driven to the wall by the one trade paper which has dared to tell the truth for fifty-two consecutive weeks, Electricity.

……o……

It is fortunate for the stockholders of the General Electric Company that it only did a trifle less than $14,000,000 of business for the first year. Losing about seventy-five cents for every dollar of business done, twenty millions of business would have wiped the stock completely out.

……o……

Mr. B. E. Sunny, general manager of the Chicago office of the General Electric Company, was summoned to this city by telegraph last week, to explain how it came about that the final balance sheet of his office for the year showed a net loss of a quarter of a million dollars; also how it was that he sold to the Pueblo (Consolidated) Railroad Company $175,000 worth of apparatus, taking in payment therefor second mortgage bonds, there being already $225,000 first mortgage bonds on the property, the road now running behind at the rate of about $1,000 a month on operating expenses alone, saying nothing of defaulted interest on the first mortgage bonds. It is not known as yet whether Mr. Sunny convinced Mr. Twombly that this was or was not good business.

On a Method of Governing an Electric Motor for Chronographic Purposes.

BY DR. A. G. WEBSTER.*

The element of time is one of the important quantities upon which electrical measurements pend, and many of the most fundamental determinations, such as the absolute measurement of resistance, the determination of "V," the ratio of the two electrical units, measurement of capacities and of coefficients of inductions, involve a time-measurement as one of the principal data. The measurement suffers under the disadvantage that it cannot be preserved in a material standard, for while the meter and the kilogram are defined by prototypes deposited at Breteuil, the second cannot be so deposited nor directly copied. Nevertheless the instruments for the measurement of time have reached such precision in our astronomical clocks and chronometers that we have little to complain of.

In electrical measurements, however, the element of time generally enters as an angular velocity, and the difficulty enters not with the clock, but in the preservation of the angular velocity constant enough for accurate measurement. Of course a clock is but an instrument for preserving a constant angular velocity, and when the velocity is small nothing else is to be desired. In our electrical measurements, however, angular velocities are large, and clockwork is out of the question. Clocks and chronographs, escapements and governors, moreover, are at best delicate and expensive, so that no apology is required for an attempt to find something less so.

Next to a clock with a pendulum or balance wheel, a tuning fork is a good time-keeper, and has been adopted, or what amounts to the same thing, a reed has been used to govern a clock-train, in the Hipp chronoscope. The accuracy of the latter is, however, not all that could be desired. In electrical measurements the tuning fork has been of the greatest service, and is the instrument upon which the time measurement generally directly depends, the fork being used by the stroboscopic method to verify the constancy of the angular velocity.

The question of the maintenance of the constant velocity remains unanswered. It has often occurred to me to ask why the electric motor has not been applied in chronographic apparatus, and it seemed to me that this could often be done with material reduction of expense. In the course of some experiments last winter, when it was necessary to measure intervals of time of the order of a thousandth of a second with an accuracy of one part in ten thousandth if possible, so that an interval of ten millionth of a second must be distinguishable, and high velocities were necessary, clockwork is out of the question, and I determined to try the motor, and to attempt to give it a positive governor.

---

* Paper read at the International Electrical Congress, Chicago.

The method adopted was of such simplicity that it must have occurred to all present, and was suggested by the method employed by Lord Rayleigh, and elaborated at the German Reichsanstalt, for comparing a tuning fork with a clock by means of Lacour's phonic wheel. The prevalence of the synchronous alternating current motor also suggested the practical means needed.

Upon the shaft of a small motor carrying a drum and disk for registration was directly attached the armature of a smaller motor arranged as an alternator, with separately excited field magnets. The current for the armature of the latter was made alternating by a commutator arrangement, composed of mercury cups and wires carried by the prongs of an electrically maintained tuning fork. The direct current motor was now run up to synchronism, in hope that the alternator would fall into step with the tuning fork, and be automatically governed. As it is obviously out of the question to pass more than a very small current through a mercury break, the question of phase is equally important with that of synchronism, and it was at first found impossible to make the governor work at all. It was soon found that an alternating current was not necessary, but that an intermittent current would serve as well, so one of the reversed currents was left out, and the complicated commutator on the tuning fork was reduced to a simple break.

In order to throw on the governing current at the right phase, a mirror was placed upon the end of a shaft, so that its normal was slightly inclined to the direction of the axis, so that a point of light would be seen as a continuous circle. A glow lamp reflected in a mirror, carried by the governor tuning fork with an interposed slit, was looked at in this mirror, and instead of a continuous circle of light there was then seen a number of bright arcs, which diminished as the speed of the motor was brought up to synchronism. When the number of arcs is reduced to two, synchronism is attained, if the arc stands still; in practice, however, by means of a fluid rheostat in the circuit of the field magnets of the driving motor the speed is made gradually to vary, so that the arcs revolve slowly, and when a part of the revolution is reached that a few trials show to denote the proper phase, the governing current is thrown on, and the apparatus runs controlled, and the arcs of light stand perfectly still. In order to give instant notice of a failure of the governor, a telephone was placed across the terminals of the armature, which spoke up in stentorian tones of beats on the least divergence from synchronism, so that the observer would be recalled even from the farthest part of the next room. An amperemeter also showed by the presence or absence of oscillations corresponding to the beats when the governor was acting properly. The motor which I used for driving was capable of giving out one third of a horse power, and the number of revolutions was thirty-two per second. The tuning fork was a large electro-magnetic fork by König, carrying a steel mirror and a sliding weight.

In order to make sure whether the frequency of the tuning-fork was influenced by the controlling current, a large free fork was set up near by and was frequently bowed and compared with the electro-magnetic fork by means of Lissajou's figures. No difference was ever detected whether the governing current was on or off, although a difference of one part in twenty thousand could have been detected.

The accuracy of governing by this method is of course only limited by the constancy of the frequency of the electro-magnetic fork. In my experiments this generally amounts to about one part in ten or fifteen thousand, but I have no doubt that by the exercise of proper precautions it could be made much greater. This method dispenses with the services of one observer, and gives a marked increase in the accuracy of the determination of angular velocity, one of the most troublesome measurements concerned in electrical measurements, so that I am left to hope that it may prove of practical utility in future determinations.

Current Items.

A boom in the electrical business in Southern cities threatened with yellow fever should be looked for at once, if the opinions of Mr. Park Woodward, of Atlanta, carry any weight. He says: "I can tell you why Atlanta can bid defiance to yellow fever and other plagues. It is because the earth is thoroughly charged with electricity from the street cars, telephones, telegraphs and city lights. All these combined keep the earth's surface like a huge electric battery. This kills any disease germ that may find their way into the city. You know it is a fact that the Western Union telegraph office has its ground wire across the Chattahoochee river, because the earth was too much charged with electricity to ground it in the city."

It is announced that the Illinois Central Railroad has discovered a new and valuable use for electricity. It is for nothing else than to kill weeds along the roadway. In order to comply with legal requirements in years past it has cost the company about $40 per mile to destroy the weeds. With the electric annihilator five miles of weeds can be killed in an hour at very small expense. The heavily charged brush runs along about eight inches above ground, and any weed with which it comes in contact, however big or strong, is struck dead, as it were, and becomes black as if smitten with frost.

On the Carrying Capacity of Electric Cables, Submerged, Buried or Suspended in Air.—II.

(Continued from Page 93.)

thermal resistance is again interposed by each layer of fibrous material, the thermal resistance of the metallic bands or wires being negligible in comparison. The thermal resistance of any cylindrical layer of resistivity δ_n and radii r_n and R_n is $S_n = \frac{\delta_n}{2\pi} \log_e \frac{R_n}{r_n}$ by formula (2), and since all these resistance are in series, the total thermal resistance per centimetre of cable length is $(S_1 + S_2 + S_3 + \ldots G)$ and this compound term should replace the symbol S in equation (4).

As the measurements referred to were all made on simple lead-covered cable, information is still missing as to the value of the resistivity for these layers.

In computing the tables given in Appendix III, these resistivities have been assumed as equal to that of the Siemens insulator next to the copper, i. e., $\delta = 750$.

INFLUENCE OF NEIGHBORING ACTIVE CABLES

If two or more active cables are buried in the same trench, they will exert a mutual thermal influence upon each other, and it becomes important to ascertain in what degree their proximity will influence their temperature elevation and safe carrying capacity.

As an illustration of the distribution of temperature communicated to the soil in the vicinity of an active cable, Fig. 2 represents the special case of a cable whose axis is buried forty radii below the ground surface. If the external diameter of the cable should be 5 cms. (1.97"), the depth will correspond to one metre (39.37"). Taking the temperature elevation at the external surface or sheath of the cable as standard, the circles indicate the sections of successive isothermal surfaces having 95, 90, 85 per cent.—10 per cent. of the sheath elevation, the ground surfaces being the postulated surface of zero elevation. It is evident that for a given distance from the cable the temperature elevation is highest immediately beneath, and lowest immediately above it. The following table, No. II, gives the horizontal distances at which these isotherms occur, measured from the cable axis, and this series is represented by the curve in Fig. 3.

These entries and diagrams by representing a dimensional system of common occurrence in practice may enable temperature elevations at different distances from an active cable determinable in some cases by direct inspection. The data, however, for constructing the diagram corresponding to Fig. 2, appropriate to any given case, are provided in Appendix II.

In this case, if the temperature elevation at the cable's sheathing should be 10° C., and a second cable should be placed in the same trench and parallel to the first at an interaxial distance of 22.7 cms., the table and curves show that the second cable would have its temperature raised by 50 per cent. of that at the sheath of the first, namely, 5° C., and if 25° C. constituted the limiting safe temperature elevation above normal, then the limit of self-elevation allotted to the second cable would be reduced to twenty degrees. The same process might be extended to any number of cables buried in one trench. A diagram could be prepared showing the relative positions of the cables, and the elevation of any one would be the sum of the elevations due to all the remaining active cables taken in turn as though each acted alone. This sum would represent for that cable the total elevation above normal due to mutual influence, and should be subtracted from the range of self-elevation in assigning the limiting current strength. This proceeding not only involves the previous assumption that the temperature elevation of the ground surface is negligible, but also that the insertion of parallel idle cables into an otherwise homogeneous environment does not affect the thermal distribution previously existing. This, of course, could be only true for cables of infinitesimally small cross section. The effect of the location of a sheathed cable in the vicinity of other active ones must be to equalize the temperature throughout the space it occupies, and this tendency must

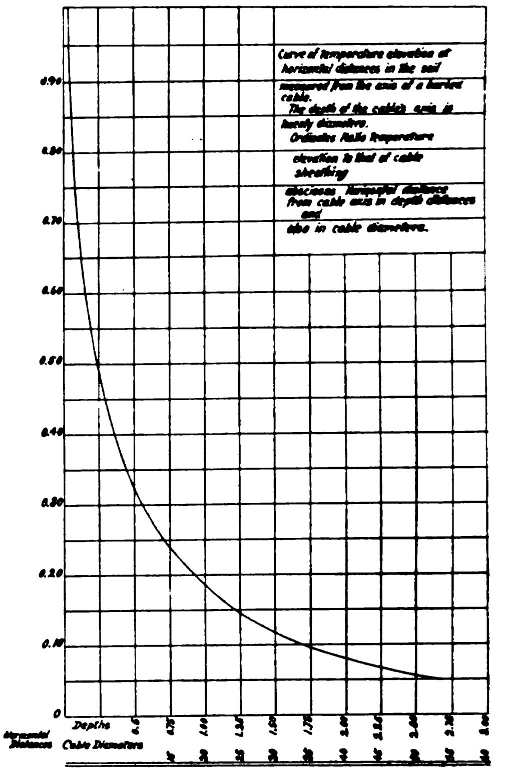

FIG. 3.

exert a disturbing influence, diminishing with distance, over all parts of the thermal field of distribution. The nearer the cables are packed together, and the greater the ratio of their diameters to their depths, the greater will be the discrepancy due to both these incorrect assumptions, but it would seem that for ordinary sizes, depths of from 60 to 120 cms. (2 to 4 feet), and distances apart of 30 to 90 cms. (1 to 3 feet), this error will not be serious. Observations made on cables horizontally separated by 11.4 diameters in the same trench showed that the temperature of one kept inactive acquired in three hours 38 per cent. of the temperature elevation at the sheath of its active neighbor, the calculated elevation being 42 per cent.

Fig. 3 shows that for the depth there considered the temperature elevation at a horizontal distance of twenty diameters is less than 20 per cent., while at five diameters it is nearly 50 per cent. of that at the sheath of a continuously active cable. With heavy cables, maintained for long periods of load in soils of high thermal resistivity, their distance apart in the trench may thus become an important matter.

INFLUENCE OF DURATION OF LOAD UPON TEMPERATURE ELEVATION.

The temperature elevation of a cable with a given steady current, in the sense ordinarily intended, is that maximum elevation which is only attained after an indefinitely long period of activity. The problem of the temperature development throughout time, in and round a buried cable, may be solved on the postulate of a constant normal temperature of the ground surface, by considering two equal and parallel cables in the same vertical plane and at a distance apart of twice the trench depth, but with the ground now distributed round them for an indefinite distance in all directions. If the lower cable generates heat at a given rate, and the upper cable absorbs (or generates negative heat) at the same rate, the temperature of the mid-plane between them, corresponding to the actual surface of the ground, must remain by symmetry undisturbed, and the distribution of temperature below this plane due to the independent temperature distributions from both cables, advancing with time, will in algebraic sum correspond to the distribution developed by the actual cable. The problem therefore reverts to that of determining the distribution of temperature in an indefinitely extended medium surrounding a long straight cable steadily supplying heat, and the materials for the solution of this case have been supplied by Fourier. It would appear that under practical conditions the temperature elevation in and near the cable tends to reach its maximum with comparative rapidity, the approximation to the final state being more tardy as the distance from the cable increases. In the measurements of the temperature elevation of buried samples, the elevation of sizes up to 200,000 circular mils (1.014 sq. cms.) appeared to attain 95 per cent. of their full value in the conductor within twenty minutes, and the increase became inappreciable after one hour. On the other hand, while, as already remarked, a parallel idle cable 11.4 diameters horizontally distant reached 38 per cent. of the active cable's sheath temperature in three hours out of 42 per cent. calculated, another idle cable at 22.8 diameters appeared to reach only 17 per cent. out of a calculated 29 per cent. in the same period, a discrepancy that may well have been due to time lag. It may therefore be safe to infer that the conductor of a buried cable will closely approximate to its ultimate temperature elevation in one hour of steady load, but there can be little doubt that many hours will be needed to establish an equal approximation to the final state at a distance of say forty diameters from the cable.

(To be continued.)

A New Incandescent Arc Light.—II.

BY L. B. MARKS, M.E.*

DISTRIBUTION OF LIGHT.

It will be seen that the distribution of light as shown by the candle power curve differs considerably from that of the ordinary arc. Especially is this true at angles greater than 50° below the horizontal. The turn in the curve is not so sharp as in the arc, and there is much less difference between the maximum and the mean amount of light; in fact to the naked eye the intensity of luminous radiation does not seem to vary much from 20° to 60° below the horizontal, while in the arc the change is very marked between these limits. Thus the formula of Gerard,[1] namely:

Hemi-spherical c. p. = ½ horizontal c. p. + ¼ maximum c. p., which may be used to advantage in arc light approximations, will not hold in this case; but the form of the curve, as well as the nature of efficiency curves above referred to, suggests the substitute.

Hemi-spherical c. p, = ½ horizontal c. p. + ½ maximum c. p.

The mean or hemi-spherical candle power below the horizontal, obtained by integration of curve Fig. 3 equals 431, thus allowing 1-17 watts per candle, or 637-6 candles per electrical horse-power, nearly three times the average illumination of the incandescent lamp using the same energy.

The results of tests show that the mean hemi-spherical candle power of the ordinary arc measured as in the above case averages about 600; the mean watts per candle, .84 or 888 candles per electrical horse-power.

Comparing these measurements with those of radiant efficiency, it appears that the ratio,

$$\left\{\frac{\textit{Hemi-spherical c. p., ``incandescent arc,''}}{\text{Hemi-spherical c. p., ordinary arc.}}\right\}$$

is considerably smaller than the ratio,

$$\left\{\frac{\textit{Hemi-spherical efficiency, ``incandescent arc.''}}{\text{Hemi-spherical efficiency, ordinary arc.}}\right\}$$

The explanation of this difference undoubtedly lies in the quality of *luminosity* of the light emitted by the *incandescent arc*. Nichols[2] has pointed out that the relative efficiency, as determined by the ratio

$$\left\{\frac{\textit{luminous radiation,}}{\text{total radiation,}}\right\}$$

"does not coincide with that obtained from the ratio of watts to candle power, for the reason that the various rays which make up the visible spectrum do not enter into the production of candle power in proportion to their energy.". Luminosity is a potent factor in determining the real efficiency of any source of illumination. Lack of time has prevented the investigation of this important phenomenon, but, at its maximum efficiency the light from this form of *incandescent arc*, though not so intense, unmistakably appears brighter than that of an ordinary arc of equal candle power as interpreted by the photometer.

LIFE TESTS.

Oxygen being practically excluded from the arc enclosing chamber, prolongation in the life of the electrodes is an implied concomitant.

In the ordinary arc "while the positive carbon loses by volatilization from its tip or crater, and by combustion from its sides, the negative gains no deposit, but wastes at a less rate than the other, and by *combustion only*."[3]

Hence, if the exclusion of oxygen were complete, we might expect an indestructible negative. This condition, however, has not been fulfilled in any of the tests made thus far, but the results fully substantiate the theory. Absence of combustion on the one hand, and the tension of the enclosed gases on the other, combine to greatly reduce the amount of disintegration of the positive electrode.

Table IV gives the results of life test with a pair of pure carbons, ½ in. diameter, and specially constructed for the purpose.

The lamp was placed in the circuit of a constant current dynamo, running about eight hours per day; readings were taken at given intervals and the total length of run was limited to 100 hours.

Table IV.—Life Tests.—½ in. Carbons.

Mean Currents 9 9-16 Amp. Mean P. D. 55 Volts.

Initial length [x] carbon *inches*	Initial length [—] carbon *inches*	Duration of run *hours*	Loss in length [x] carbon *inches*	Loss in length [—] carbon *inches*	Life per inch [x] carbon *hours*	Life per inch [—] carbon *hours*
10.31	4.63	100.	6.81	0.69	14.67	145.45

Thus taking 1.69 inches per hour as the average consumption of carbon in the commercial 350 watt lamp, run at 5½ amperes and 50 volts,[4] we note that although 525 watts, or one and one-half times the energy, have been expended in the case of the lamp under consideration, yet the life per inch of carbon consumed is more than *twenty times* that of the other. Indeed the figures show that the life of the negative was nearly *one hundred times* as great as that obtained in commercial practice to-day.

The preservation of the negative is a very interesting feature of this type of lamp. There is a marked tendency towards deposition of the products of volatilization of the upper electrode on tip of the lower, the carbon deposited, if not ruptured by the action of the lamp, forming an internal part of the negative.

In one case where, the arc having been sprung, the electrodes did not come in contact during the entire run, this "building up" process was beautifully exhibited, the negative electrode gaining practically all that the positive lost. The current in this instance was 10½ amperes, and the P. D. 50 volts. The duration of the run was eleven hours.

OBSERVATION OF THE ARC.

Relation of P. D. to Length of Arc and Quality of Carbon.

The effect of the enclosed gases on the form and character of the arc presents a large field for investigation.

On account of lack of sufficient data no attempt will now be made to state much of a definite nature regarding this subject; but it is hoped that the matter will be given due attention in the near future.

The difference in potential between the electrodes being equal, the *incandescent arc* is longer for a given current than the ordinary arc; under some conditions it has been found to be almost twice as long. If we accept the conclusion of S. P. Thompson, that "the arc is independent of the nature of the surrounding gas,"[5] we must then look to the effects of the tension or pressure of the heated gases upon the arc to explain this difference in length. It has been found that there is a constant increase of P. D. with pressure above atmosphere for a given current and length of arc.[6] But in spite of this fact, the decrease in resistance of the arc under the conditions named appears to allow of a greater length for the same P. D.

FLAMING AND HISSING.

In the ordinary arc the carbon vapor carried off from the positive is consumed by the oxygen of the air before it can deposit on the negative.

Hence the ever present "zone of flame" as distinguished from the arc-flux proper is really a zone of combustion. In the *incandescent arc*, however, there is naturally no zone of flame, consequently the phenomenon of *flaming* common to the ordinary arc does not occur. The arc tends to centre itself, being probably aided in so doing by the pressure of the surrounding gases; moreover, the slow consumption of the electrodes lessens the tendency to wander. With cored carbons there is a perceptible crater, but with solid pencils the tips become more or less flattened.

The quality of the carbon has an important bearing on the P. D. between the electrodes. Generally speaking it has been observed that with soft fine-grained carbons the P. D. is considerably lower for a given current than with harder or coarse-grained pencils. The tendency to *hiss*, however, is not so marked when the electrodes are consumed in the gas chamber as in the open air; in the former case the disintegration is so slow that the "electrolytic" vaporization, as it has been called, does not appear to explode the particles. It is interesting to note here that these results confirm a theory of *hissing* advanced by Prof. Thomson a few years ago.[7]

THE ALTERNATING CURRENT "INCANDESCENT ARC."

No measurements were made using the alternating current, but the appurtenance was applied to the alternating current arc-lamp to determine the effect on the noise of the arc. The *hum* was in a large measure reduced, but whether the reduction was due mainly to the mere fact of the arc being enclosed in an air-tight compartment or not is questionable. But, as the *hum* became much slighter after the lamp had been in operation several minutes, the action of the heated gases being then manifest, it is plausible that the diminution in the noise was not due entirely to the shielding property of the glass envelope.

While it has been proven that "the humming of the alternating arc due to the rapid periodic extinction and re-establishment of the discharge,"[8] the singing tone may be greatly modified, if not entirely overcome, by the substitution of any incandescent arc of the Reynier type. A few years ago the writer had occasion to test an alternating current arc-lamp trimmed with carbons which had been provided with a core of pulverized mica and carbon. The springing of the arc was accompanied by the usual *hum*, but as soon as the mica fused the noise ceased. The conditions were similar to those of an *incandescent arc*, the plastic mica-carbon core constituting a high-resistance medium between the plus and minus electrodes. There was really no true arc. The amount of light was naturally greatly reduced. In the case of the *incandescent arc* first alluded to, there seems to be an approach to these conditions, the arc-steam acted upon by the gases enclosed in the chamber appearing to have a greater density, if we may call it that, than under normal circumstances. The amount of light in this experiment was, however, apparently as great as in the direct current tests.

APPLICATION TO THE ARTS.

Unquestionably this form of *incandescent arc* must have a wide application to the arts. As a substitute for the ordinary arc-light, where greater steadiness or longer life is required, its superiority will be manifest. And its utilization, where at present the incandescent lamp is the only satisfactory source of illumination, also presents a large field. The effective distribution of luminous energy and the color of the light, make it for many purposes a desirable mean between the incandescent and the arc.

As a standard source of illumination for arc-light comparison and measurements, it may be of much scientific as well as utilitarian importance.

The investigations have been carried out under the direction of Mr. Louis E. Howard, and many of the facts herein stated are due to him. The writer is also indebted to Dr. Edw. L. Nichols, Franklin L. Pope and Rob't H. Read for valuable suggestions; to Mr. C. Ransom for life tests, and to Messrs. Wm. C. Hubbard and E. S. Ferry for assistance in the efficiency and candle power measurements.

(*Concluded.*)

American Electrical Works.

The 15th Annual Picnic and Gathering of the Clans for a General Jollification and Eating of Clams.

Yes, it was a remark full of truth which fell from a member of the electrical fraternity when he received an invitation to the fifteenth annual clambake, tendered by the American Electrical Works, Providence, that the little card was like an oasis greeting the eye in the midst of the arid desert of financial and commercial depression which at present extends from the Atlantic to the Pacific boundaries of this fair land; and, as events proved, the boys availed themselves of the kindly call to partake of the generosity tendered by "Little Rhody's" most popular citizen for and in behalf of a firm known and esteemed by every member of the great electrical fraternity.

Saturday last, September 2, was the date, and Haute Rieve, the rendezvous on the beautiful Providence River, where this notable gathering took place. The day broke dull and damp, and the weather man evidently was inclined to provide conditions almost as depressing as the times for the occasion, but his inclination, if such it was, failed to spoil what has come to be known as "Eugene's weather." Nevertheless, the unpromising outlook did something towards frightening a few of the less brave ones from journeying to Providence, there to participate in the slaughter of the innocents by immolation on the altar for the delectation of the gastronomic organs of a crowd of hungry picnickers. Those, however, who did brave the threatening elements, and they numbered 155, were more than amply repaid, for just as Providence was reached by the Boston contingent old Sol showed his radiant face from behind the dark clouds and was considerate enough to remain on view more or less the rest of the day—so the boys, as usual, had an ideal outing.

By way of a change, the trip to the trysting place was not by steam, but by electric cars, which run now down to Crescent Park, close by the picturesque grounds of Haute Rieve, alias the Union Club House.

Lunch was announced for 11:30, and to the minute the well-loaded tables were besieged, and a spirited attack made on the comestibles, which included clams, quohaugs, oysters, lobster, doughnuts, crackers and cheese, these toothsome dainties being pleasantly diversified by draughts of punch such as the greatest connoisseur might smile over and feel happy and good. This item of the day's programme ended, the registering of names and the attaching of badges completed, the day's fun began in right good earnest.

There was a phonograph, delivering speeches on the silver question, and singing songs composed by electrical men; a galvanic machine tying the arms in knots and compelling the bold ones to perform acrobatic feats of questionable grace; lifting machine for testing the strength; rifles and targets for those who fancied they knew how to handle a gun, and other attractions. Of course, the usual supply of white hats, and wide expanding sombreros was forthcoming to adorn the heads of many, and kicked round as freely as the ubiquitous football which found lodgment on many a pate as it was sent flying from point to point in the lunch room.

Soon a baseball game was arranged for, the contending teams representing Boston and Providence respectively, the result of five innings showing a record of 30 in favor of Boston to 12 for Providence.

And so the fun went on until the bake proper was announced, in a huge tent. And such a repast! It need not be here described, for all know that it included many delicacies and appetizing dishes besides the historic and succulent clams. The menus were passed around incased in miniature traveling rugs and straps, which novelty will long be preserved by the guests as a souvenir of this enjoyable gathering.

The esteemed host, Mr. Eugene Phillips, presided at the head of the tent, having Mr. C. E. Stump, of New York, as toastmaster. In opening the post-prandial exercises Mr. Phillips gave a hearty welcome to all present; expressed the pleasure it afforded himself and his associates to have as their guests so representative a gathering of men engaged in the electrical industry. Notwithstanding the business depression that almost universally prevailed, there were causes for congratulation all round, and he for one did not believe in giving way to feelings of despair, for he had the assurance that things would correct themselves very shortly, and in any event he desired that all should enjoy themselves thoroughly, and if they found it difficult to take their day's pleasure silently, why they were at perfect liberty to make all the noise they could.

Mr. Martin C. Day, the facetious city editor of the Providence *Journal*, then responded to a call with one of his funny speeches, which, as usual, convulsed the entire company. Mr. Frank Ridlon, as one who had attended many of those clambakes, spoke feelingly of the past and most appreciatively of the debt of gratitude Mr. Phillips had laid upon the whole electrical fraternity by his princely hospitality. Mr. H. M. Dagget, Jr., of Attleboro, made a few timely remarks on the great work which was being done by those present as representing one of the greatest industries of the age, and was followed by Captain Brophy, who, as one esteemed by everybody, spoke of what he wes always trying to do in harmonizing the two important interests, electricity and insurance. He eulogized Mr. Phillips as a gentleman who had done so much for this world that some day he might be invited to emigrate to some other planet and there show the inhabitants of another sphere what can be accomplished by an enterprising business man and a true, generous-hearted gentleman.

Mr. W. S. Key, representing the electrical press, said a few words for those engaged in journalism, expressing the hope that as the press had always striven to advance the science and art of electricity, so it would always stand for what was best in the business, aid it in its progress and throw in its influence towards restoring confidence and helping on renewed progress.

Mr. H. B. Cram, Boston, in a brief address pathetically alluded to those who were no longer to be found at these festive gatherings, having passed on to the great majority, while others equally familiar and well known had found it impossible to be present because of important duties they were now discharging at Chicago and elsewhere in connection with the electrical business in which all present were so deeply interested.

The speeches were necessarily brief, as the boys had lots of fun left in them, and at the close of the exercises, which had been interspersed by music discoursed by an orchestra, the fun was resumed until the morn, when many had to start for home, quite a number on their way to the depot visiting by invitation the Narragansett Electric Light and Power Station, to see the starting up of the huge 500 kilowatt alternating machine, which proved a great attraction to all who saw the monster and watched its start. It will be many a long day ere those who were privileged to be present will forget the pleasure and enjoyment of the American Electrical Works' 15th annual clambake.

Boston Notes.

Slowly but surely confidence in business circles is returning hereabouts, and local electrical firms are already beginning to feel its effects. The all but complete paralysis that was induced and became so general two or three weeks ago has not, by any means, been replaced by a healthy condition of trade such as prevailed ere the sudden panicky feeling struck the country; nevertheless there is a perceptibly healthy reaction, which, of course, everyone is hoping will continue. Several firms actually report themselves busy, and their reports are substantiated by the activity that abounds in their factories. Not only are these not laying off their men, working short time, or reducing wages, but, on the contrary, they are running full blast, and experience some difficulty in keeping pace with their orders. Several New England firms are in that notable condition, and we trust it may be our pleasure to have to report continued progress and improvement next week. If nothing else will, the devastation and havoc wrought among electric wires this week by the frightful storms should cause the wire trade to brisk up promptly, and this is just what it has done.

The electrical fountain that is to adorn the beautiful Lynn common, in the heart of the City of Shoes, as a gift from a late wealthy citizen named William Shute, is getting well under way and is to be inaugurated, all being well, on September 15. The one difficulty the designer and builders have to contend with is the low pressure in the street mains, which will limit the main stream of water from the fountain to a height of 25 feet only.

A few weeks ago we announced the fact of the City Council of Manchester, N. H., having been indicted by leading citizens for having made what was considered an illegal contract with the Manchester Electric Light Company for lighting the city for a term of ten years. There are rival electric lighting companies in Manchester, and this fact is at the bottom of the trouble. On Tuesday last the Mayor was served with a notice that at the September term of the Supreme Court certain petitioners, citizens of Manchester, would ask the court to break the contract recently made by the city government with the above company. The petitioners allege that the contract of ten years duration is beyond the authority of the city to make; that the Mayor and City Council are but the public agents of the city as a corporation, hold their authority in the nature of a trust, and this trust is grossly violated by the action of said officers and the misrepresentation and fraud of said light company in making said contract. Complainants further allege that under this pretended contract the city agrees to pay over $30,000 a year, or over $500,000 for ten years, for lighting the streets of the city, while a contract might have been made at a saving to the city of $10,000 or more a year. Other allegations were also made in the petition, which is signed by some twenty-five taxpayers. It is understood to be pressed by the rival electric company, but a move is believed to be on foot to consolidate the two companies, in which event the suit would probably be permitted to fall through.

The Usher storage battery, which is doing such excellent service and practically demonstrating its high efficiency on the Milford and Hopedale Street Railway, every car on which is operated by this battery, has attracted so much attention among capitalists and representative railway men in England that negotiations are now in progress with a view to the sale of European rights to a wealthy syndicate on the other side. An expert has gone to England, and it is confidently believed that as soon as the foreigners have had an opportunity of seeing this battery at work they will secure all rights in it for Europe.

There is a new electric car motor in process of construction in this city, which has two armatures so arranged that they will revolve at two different speeds, the fundamental idea at the basis of this peculiar construction being to secure a more ready and easy method of taking curves on street railways with the two armatures, it being found that the speeds are differentiated according to the radii of the two rails on every curve. As will readily be appreciated, the varying speed of the wheels on the outer and inner rails will do away with the friction incidental to the usual method of both wheels revolving at the same speed.

General News.

What is Going on in the Electrical World.

Auburn, N. Y.—The common council has decided to use electric lights only for street lighting; hitherto gas has been used.

Martin's Ferry, W. Va.—The property of the Martin's Ferry Construction Company, consisting of the ruins of the electric plant, poles, wires, franchise, etc., are to be sold.

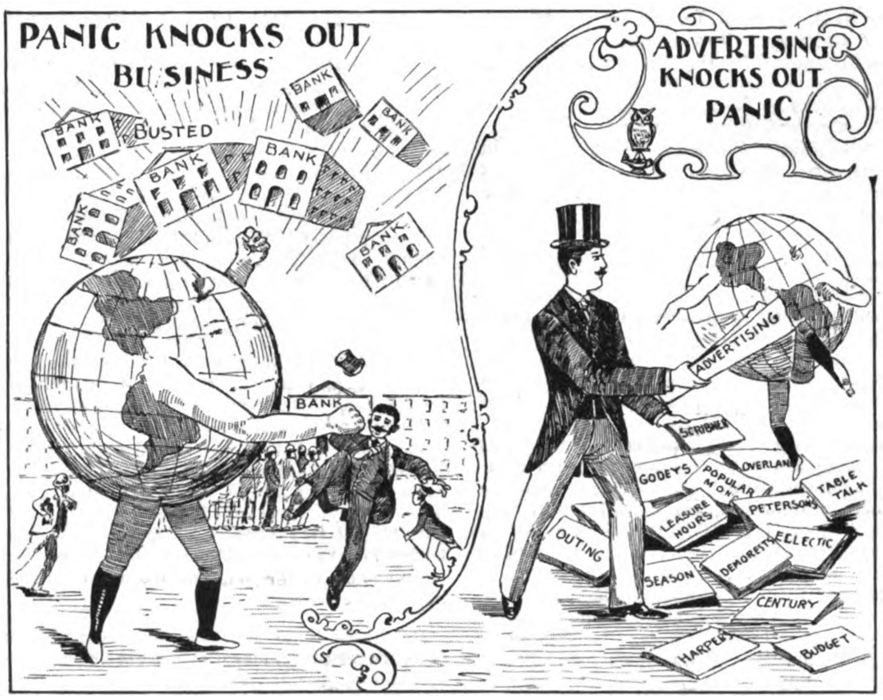
Clinton, Mass.—Surveys have been made for an electric road between Clinton and Sterling Junction, the scene of large annual camp meetings and a favorite summer resort.

St. Paul, Minn.—The East Seventh Street cable line has been transformed into an electric line at an expense, including losses by the change, of between $300,000 and $400,000.

Columbia. S. C.—The city council, owing to some disagreement with the electric light company, have under consideration the question of putting in a plant under city ownership.

Muncie, Ind.—The city council has granted a franchise that covers nearly every street in the city to the Citizens' Street Railway Company and consolidates the motor and electric lines.

Pikesville, Md.—Committees have been appointed to dispose of stock in a proposed electric road from Pikesville to Emory Grove, by way of Owing's Mills, Reistertown and Glyndon.



AN EXPERT'S SUGGESTION.

J. WALTER THOMPSON'S VIEW OF THE SITUATION.

Paterson, N. J.—The State Electrical Subway Commission have granted permission to the Paterson and Passaic Electrical Railway Company to erect poles and run lines in Paterson.

Piqua, Ohio.—The Miami Valley Electric Railway Company has completed the building of its track between Troy and Piqua. The line will probably be extended to Dayton at an early day.

Shelbyville, Ind.—The city council has repealed the ordinance granting the franchise to the Shelbyville Electric Street Railway Company. There appears to have been some irregularity in bonding the road.

East Boston, Mass.—The Boston & Winthrop Street Railway Company has petitioned the board of aldermen for the right to construct and maintain an overhead trolley system in and through Saratoga street.

Whitesboro, N. Y.—On the occasion of turning on the electric arc lights for the first time in the streets of this place, a few nights ago, there was great rejoicing; a band paraded the lighted streets playing merry tunes.

Bridgeton, N. J.—The injunction stopping the stringing of the trolley wires of the Bridgeton and Milville Rapid Transit Company in the streets of Bridgeton has been revoked by the Electric Subway Commission.

Brooklyn, N. Y.—The Brooklyn City Railroad Company has dispensed with its horse cars, and are using the trolley only.—The Lee and Nostrand Avenue line will be operated by electricity in about three weeks.

Watertown, Mass.—The citizens of this place will no longer have to depend on the Fitchburg Railroad after the middle of September, when the electric line from Newton to Boston will be completed, the line running through Watertown.

Ansonia, Conn.—The *Sentinel* says, in relation to the Ansonia Electric Company, that "no time can be stated when resumption will take place, but it will be very soon." About 125 persons were employed in the factory at Ansonia.

Franklin, Pa.—The Franklin and Oil City Electric Railroad Company has been granted a franchise for constructing and operating a railway in the streets of this city for thirty years. The company is to pay the city $250 a year for the privilege.

Orange, N. J.—Two companies, the Consolidated Traction Company and the Suburban Traction Company, have applied to the board of trustees of South Orange for a franchise to construct and operate an electric railway from South Orange to Orange.

Toledo, Ohio.—The scheme to build an electric road between Toledo and Detroit is revived. H. J. Warner, of Brooklyn, N. Y.; H. H. Johnson, of Philadelphia, and J. H. Dawson, of Toledo, are said to be at the head of the syndicate interested in the project.

Independence, Kan.—The Continental Telephone Company has been organized here with a capital stock of $50,000, for the purpose of connecting the towns of Montgomery County with Independence, the county seat, by telephone. J. C. Reynolds, is the treasurer.

Savannah, Ga. — The insurance companies here have notified their policyholders who are using electric appliances that the latter must be made to conform to the latest rules of the Southeastern Tariff Association, otherwise an increase of 50 to 75 cents on the $100 would be charged.

Norwich, Conn.—The Quinebaug Electric Company have mortgaged their property for $300,000 with the Knickerbocker Loan and Trust Company, and intend to erect a dam twenty-two feet higher than the Greeneville dam and otherwise increase their facilities for furnishing power by electricity, lighting, etc., to surrounding towns.

Hartford, Conn.—The council has again shown its hostility to the trolley system by refusing to reconsider its former action against an application from the Horse Railroad Company to use it on their lines. The councillors demand a trial of the storage system by the company. If that proves a failure, they may accept the trolley.

Atchison, Kan.—A Salina paper states that Morton & Company, bankers and brokers, of New York, have offered $35,000 cash for the Atchison Street Railway, and will operate it with electricity if a bargain is made. All they ask of Atchison is that the city donate a site for a power house and an ice manufactory.

Utica, N. Y.—A meeting of the stockholders of the Baxter Overland Telephone and Telegraph Company has been called for September 15, at the office of the secretary, in this city. At this meeting an attempt will be made to secure the consent of three-fourths of the stockholders to mortgage the property of the company for the sum of $10,000 in order to satisfy several judgments held against the company.

Kansas City, Mo.—F. F. Hadley and W. E. Winner have filed an application in the county court for a license to construct and operate an electric line on East Fifteenth street from the end of the cable line to the Blue river, tapping Manchester and Centropolis, manufacturing suburbs of Kansas City. The applicants are owners of a tract of 100 acres on the Blue River lying on the route of the proposed line. This tract they say they intend to convert into a park.

Lawrence, Mass.—A company with a capital stock of $90,000 has been formed to build an op-

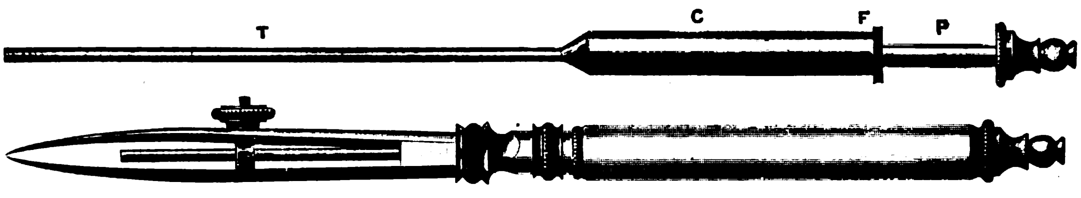
position line to the Lowell, Lawrence and Haverhill Electric Railway. The tracks of the proposed line will extend along the south bank of the Merrimac River through the towns of Andover and Tewksbury to Lowell. Among the promoters of the new line are: Maynard E. Clemons and Winslow Goodwin of Andover, C. T. Guild of North Attleboro, A. C. Russell, J. I. Chalifoux and Larkin T. Trull of Lowell, and W. S. Knox of Lawrence.

The "Injector" Reservoir Drawing Pen.

Draughtsmen know well the trouble and bother experienced (especially in doing details, etc., in which strong lines are employed) in being repeatedly called upon to "dip, dip, dip, and wipe, wipe, wipe," when using an ordinary ruling pen. An invention which obviates this in a very high degree must indeed, to quote a hackneyed phrase, "meet a long felt want."

Such an invention is now on the market. It consists of an ordinary hinged-nib Drawing Pen, provided with a hollow celluloid handle, into which fits a cylinder C, which is shown withdrawn from the handle in the lower illustration. The rod or plunger P serves to draw the Indian ink into the cylinder C, while the tube T is provided to carry the ink to between the nibs of the pen; the whole reservoir attachment, as will be seen from the lower illustration, constituting in reality a miniature hand pump.

To use the "Injector" Pen, withdraw the cylinder C from the handle (taking hold of the milled gland F) and fill it with ink by dipping the lower end of the tube T into the liquid and pulling out the plunger P to its extreme position. After wiping the tube, insert the whole cylinder (without, of course, disturbing the plunger) into the handle of the pen again. A slight push forward of the plunger P then serves to feed the pen with ink. When this is exhausted the plunger is again pushed slightly forward and the pen is again replenished, and so on.



JACKSON BROS.' "INJECTOR" RESERVOIR PEN.

Excellent points in this new invention not already mentioned are:

1. If it is wished to interrupt the work it is only necessary to blow out the ink remaining between the nibs of the pen; the ink in the cylinder will keep good for days.
2. If it is desired at any time when the reservoir is empty to add a line or two to a drawing without replenishing the reservoir, this can be done, for the pen can be used exactly as an ordinary pen, and further, should the reservoir attachment be lost or damaged an excellent Drawing Pen still remains.
3. If the top of the cylinder is unscrewed by means of the milled gland F, the plunger P can be easily withdrawn for tightening or renewing the packing.
4. The price at which the "Injector" Reservoir Pen is offered is actually less than is often charged for ordinary hinged-nib Drawing Pens, viz., 4s. each.

The pens are made by Jackson Bros., Limited, 50 Call Lane, Leeds, Eng., and are offered at 4s. each. American agents are wanted.

The "Novak" Lamp.

Mr. Arthur E. Bowers, New York manager for Claflin & Kimball, selling agents for the "Novak" Lamp, has removed his office to Room 63, *Tribune* Building. The following features of merit are claimed for the "Novak" lamp, by the manufacturers:

"The lamp now manufactured by us is a total departure in principle from all other incandescent lamps. Our lamp will maintain its initial candle power at its initial efficiency throughout the usual average life of incandescent lamps.

"The importance of this improvement can only be realized by those who have had the usual experience with lamps which begin to lose their candle power and at the same time increase their consumption of energy as soon as the lamps are put into service.

"The 'Novak' lamp maintains its full candle power at the same efficiency throughout its life.

"The 'Novak' lamp is fully protected by patents of our own, and is free from any possible claims of infringement of other patents.

"The efficiency and average life of the 'Novak' lamp are fully equal to those of any other lamp ever offered.

"The filament used in the 'Novak' lamp is the celebrated 'Perkins' filament, the superior quality of which is too well known to need comment by us.

"We respectfully solicit correspondence in regard to the 'Novak' lamp, feeling sure that a lamp possessing the superior qualities of this lamp, and manufactured by a company whose business it is to supply the general public without discrimination, will be appreciated."

COMMERCIAL PARAGRAPHS.

The Electric Heat Alarm Company of Boston has just had issued to it a patent on a Testing and Recording Apparatus to be used in conjunction with its Electric Heat Alarm, which has proved itself to be one of the most infallible safeguards against dangers by fire now on the market. This company is achieving signal success with its special devices, which are being installed in factories, warehouses and other buildings. To be the better able to handle its increasing business the chief offices are now located at the factory, 15 Chardot street. The attractive exhibit the Electric Heat Alarm Company has at the World's Fair is bringing some excellent contracts from the West and shipments are being made right along.

Mr. R. T. White, of Boston, the well-known inventor and manufacturer of street railway tracks, cable roads, car fenders and other specialties for street railway work, has published a handsomely illustrated catalogue of his many devices, and invites in the "Introductory" all street railway companies carefully to look into the merits of his inventions. Mr. White has been a prominent man in street railway work for years and his own exclusive lines of goods have become very popular. A street railway—whether for horses, electricity or cable—constructed on R. T. White's plans and material cannot fail to be one of the best built roads in the country.

The Whitney Electrical Instrument Company of Boston reports a very satisfactory business in its particular line of voltmeters, ammeters and other measuring instruments. It is now about to place on the market a voltmeter of a special type that will work with accuracy on alternating circuits. This instrument will be made in unusually large sizes for use in central stations where it has to be consulted often from the further side of a dynamo. Hence the various parts, including particularly the index and figures, are of such size as to be easily distinguishable from quite a distance.

Mr. George W. Finch, who represents the Ball Electric Company and the Reliance Gauge Company at Escanaba, Mich., reports a decided improvement in the business feeling in that section, his sales being very flattering.

The Roessler & Hasslacher Chemical Company of New York, which has an attractive exhibit in the Electricity Building at the Fair, is receiving compliments on all sides for its enterprise. Everything needed in the line of chemicals is supplied by this firm, which is one of the most reliable houses in the trade.

A little folder with the title "Echoes from Electricity Building" is sent out by the irrepressible George Cutter of Chicago. In it are set forth the merits of Cutter's Combination Shades, Simplex Wire, etc., etc.

INCORPORATIONS.

The Pontiac Light, Heat and Power Company, Pontiac, Ill.—to deal in electric light, steam or electric power. Capital stock, $20,000. Promoters: Henry A. Foster, C. M. Hamilton and A. P. Foster.

The American Railway and Electric Light Company (incorporated in West Virginia), New York City—to manufacture and sell devices, etc., for lighting railway cars by electricity, acquire letters patent and dispose of same. Capital stock, $2,500,000. Incoporators: A. B. Cornell, Ithaca, N. Y.; Henry B. Wibert, Beriah G. Payne, New York City.

The Gas and Electric Light Company of Lincoln, Ill., has certified to a decrease of capital stock from $80,000 to $50,000.

Brown Dynamo-Electric Telephone Company, Moline Ill.—to manufacture and sell telephones, telegraphs and other electrical devices and appliances, and mechanical devices and instruments. Capital stock, $2,000,000. Promoters: James A. Brown, C. S. Brown, Henry T. Moss.

Laconia Water Power Company, Laconia, N. H.—to buy and sell real-estate and water privileges; buy and sell power by water, steam, electricity, etc. Capital stock $96,000. Promoters: Wm. C. Marshall, Jno. C. Moulton, Frank P. Holt, Sam Hodgson, J. W. Bushiel & Company.

National Thermograph and Electric Company, Chicago, Ill.—to manufacture and deal in water and steam pressure recorders, grain staffs, electric batteries, etc. Capital stock, $500,000. Promoters: E.W. Applegate, John T. Todd, Wm. J. Marks.

St. Clair Flats Telegraph, Telephone and Marine Reporting Company. Capital stock, $6,000. Promoters: William H. Conner, F. C. Gray, Lucius H. Collins, George P. Quinn, William C. Heaslop, of Jackson; Moses Schott and Sigmund Rothschild.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUG. 8, 1893

ELECTRIC RAILWAYS AND APPLIANCES.

502,821. Subway for Electric Railway Conductors. Isaac La Rue Johnson, Washington, D. C. Filed Oct. 10, 1890. Renewed Dec. 16, 1892.

502,826. Trolley-Wire Insulator. Louis McCarthy, Boston, Mass. Filed March 27, 1893.

502,842. Electric-Railway Conduit. Robert R. Zell, Baltimore, Md., assignor of one-half to Henry C. Kirk, Jr., same place, Filed Aug. 8, 1892.

502,858. Supply System for Electric Railways. Wilton F. Jenkins, Richmond, Va. Filed June 3, 1892.

503,101. Electric Rail-Bond. Benjamin C. Seaton, Nashville, Tenn., assignor of one-half to William S. Barkley, Indianapolis. Ind. Filed March 2, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

502,702. Electric-Lighting System. Cummings C. Chesney, Pittsfield, Mass., assignor to the Stanley Laboratory Company, same place. Filed April 3, 1893.

502,948. Electric-Arc Lamp. Luther H. Buchanan, Pasadena, Cal. Filed Sept. 25, 1891. Renewed Jan. 5, 1893.

503,108. Incandescent Electric Lamp. James H. Bates, Hoboken, N. J. Filed Jan. 19, 1893.

DYNAMOS, MOTORS, ETC.

502,777. Alternating-Electric Current Generator. Samuel Sheldon and John J. Rooney, Brooklyn, N. Y. Filed Sept. 28, 1892.

502,788. Regulator for Electric Generators. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed May 23, 1892.

502,988. Armature and Method of Constructing Same. Horace F. Parshall, Lynn, assignor to the General Electric Company, Boston, Mass. Filed April 10, 1893.

503,038. Regulation of Alernating-Current Motors. Michel von Dolivo-Dobrowolsky, Berlin, Germany, assignor to the Allgemeine Elektricitats Gesellschaft, same place. Filed Dec. 23, 1890.

503,106. Armature for Dynamo-Electric Machines and Motors. Schuyler S. Wheeler, New York, N. Y., assignor to the Crocker-Wheeler Electric Company of New Jersey. Filed April 24, 1893.

BATTERIES.

502,824. Secondary Battery. Lansing Morse, Brooklyn, N. Y. Filed July 25, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

502,770. Telephone-Exchange Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Oct. 15, 1888.

ALARM AND SIGNALING APPARATUS.

502,695. Synchronism-Indicator. Louis Bell, Boston, Mass., assignor to the General Electric Company of New York. Filed Dec 24, 1892.

502,734. Fire-Alarm Apparatus. Samuel W. Ludlow. Madisonville, Ohio. Filed Nov. 1, 1892.

502,811. Electric Alarm-Clock. William H. Deane, Brooklyn, N. Y. Filed Dec. 15, 1892.

503,100. Electrical Railway-Signal. Benjamin G. Seaton, Nashville, Tenn. Filed March 2, 1893.

SWITCHBOARDS AND SWITCHES.

502,768. Test Circuit for Multiple Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 27, 1886.

502,769. Lock-Switch for Electric Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Nov. 19, 1887.

502,771. Transfer System for Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Oct. 27, 1890.

502,772. Test-Signal for Multiple Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 24, 1891.

502,773. Testing System for Multiple Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 29, 1891.

502,774. Test-Circuit for Multiple Switchboards. Charles E. Scribner. Chicago, Ill., assignor to the Western Electric Company, same place. Filed July 7, 1891.

502,775. Testing Apparatus for Multiple Switchboards. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Aug. 1, 1891.

502,825. Electric Switch. Lansing Morse, Brooklyn, N. Y. Filed Aug. 22, 1892.

502,983. Electric Switch. Joseph H. McEvoy, Waterbury, Conn. Filed Dec. 31, 1892.

503,099. Multiple Switchboard System. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Oct. 13, 1891.

MISCELLANEOUS.

502,749. Circuit Closer. Augustus J. Oehring, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 7, 1889.

502,753. Electric Body Wear. William H. Payne, Philadelphia, Pa., assignor of one-half to Gustav G. Altorfer, same place. Filed Feb. 18, 1893.

502,776. Electric Belt. Jean H. Se Creverell, Jefferson, O., assignor to Henry N. Bancroft, same place. Filed June 15, 1892.

502,804. Electric Belt. Duane P. Andrus, St. Louis, Mo. Filed Oct. 31, 1892.

502,889. Circuit Testing Apparatus. Fred. S. Palmer, Boston, Mass. Filed March 20, 1893.

502,935. Self-Winding Electric Clock. Frederick M. Schmidt, Brooklyn, assignor to the Self Winding Clock Company, New York, N. Y. Filed Jan. 19, 1893.

502,965. Electrode for Firing Explosives. Joseph N. Harrison and Henry J. Harrison, San Francisco, Cal. Filed June 8, 1892.

502,981. Electrically-Operated Hydraulic Elevator. Elias Marshall, Boston, Mass. Filed Nov. 19, 1892.

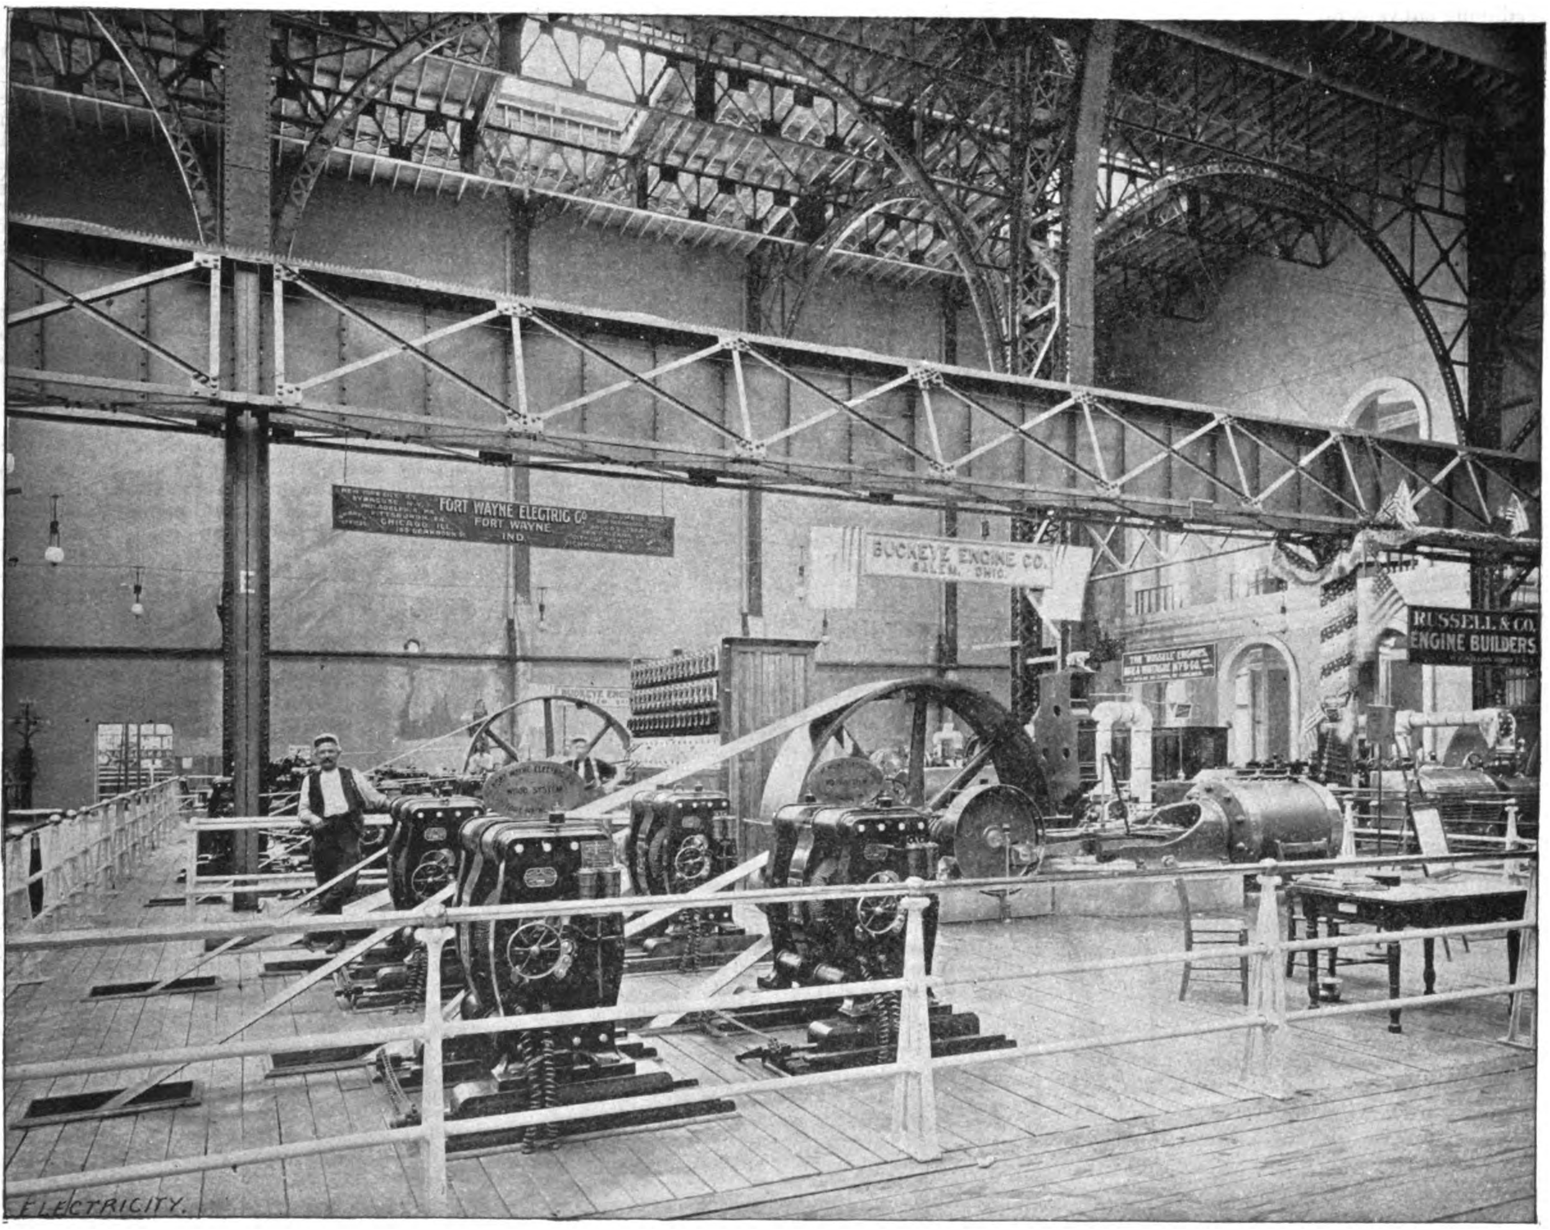
503,016. Electric Igniting Device for Gas-Engines. Frank E. Tremper, New York, N. Y., assignor to the Safety Vapor Engine Company of New Jersey. Filed Feb. 8, 1893.

503,039. Conductor Support and Insulator. William B. Essick, Manley, Neb. Filed Feb. 1, 1893.

503,076. Apparatus for the Electrolytic Manufacture of Tubes. Alexander S. Elmore, Leeds, assignor to the Elmore's American and Canadian Patent Copper Depositing Company, Limited, London, England. Filed Sept. 21, 1892.

ELECTRICITY.

VOL. V. NEW YORK. SEPTEMBER 13, 1893. CHICAGO. No. 9



FORT WAYNE ELECTRIC COMPANY'S EXHIBIT, MACHINERY HALL, WORLD'S FAIR. (SEE PAGE 110.)

Long Distance Transmission.

Exhibit of the Tesla Polyphase System at the World's Fair.

BY C. F. SCOTT.*

An exhibit of power transmission at the World's Fair which is of exceptional interest is the Tesla polyphase system, which constituted a part of the exhibit of the Westinghouse Electric and Manufacturing Company in Electricity Building. The exhibit includes generators, motors, transformers and other apparatus of various sizes and types. The system itself is not new in its general plan. There are but few features of novelty in the electrical system which have not been the subjects of publications or patents. The purpose of the exhibit is not so much to bring out what is novel in electrical invention as it is to give a complete exhibit of commercial machinery constituting the elements of a power system on a large scale. The exhibit will attract practical electrical engineers rather than those who are interested only in electrical inventions.

The purpose of the exhibit is therefore to show a complete working system for generating, transmitting and distributing power on a large commercial scale. The system includes

I. A prime mover.

II. A generating dynamo.

III. Raising converters and transmission line, and reducing converters.

IV. Motors and rotary transformers for general power and electrical service.

The prime mover in general practice is water power, but here the motor serves as prime mover. The current for this motor is received from one of the 750 K.W. two-phase Westinghouse generators of the lighting plant in Machinery Hall. The number of alternations is 7,200, and the pressure is reduced from 2,000 volts to 200 volts before being delivered to the motor. The current is delivered to the rotating element of the motor through brushes resting on four collecting rings. The winding is a drum winding laid in small slots in the surface. The stationary element of the motor is of laminated iron set in an outside casting. Large copper rods are run through holes in the iron plates near the inner surface, and are suitably connected at the ends. Resistances are put in circuit with this winding for starting the motor, and when speed is attained these resistances are short-circuited, leaving this winding completely closed on itself.

This motor drives a 500 H. P. two-phase alternating current generator. This machine is of the ordinary type of railway generator. There is a field of six poles which is excited by a small direct current machine driven by a H.P. two-phase Tesla motor of the rotary field type. The exciter in general practice would be driven by a water wheel. The large generator delivers from four collecting rings two currents differing in phase ninety degrees. The number of alternations is about 4,000 per minute, or $33\frac{1}{3}$ periods per second at a potential of 360 volts on each circuit. The machine is also provided with a direct current commutator connected with the same winding, delivering current at 500 volts. This commutator would not be used when the machine is intended as an alternating current generator only. The current from this machine is delivered to a marble switchboard, where it is regulated and connected with the various transmission circuits, as desired. This board will afford facilities for connecting various circuits with any one of the several generators which may be placed in a large generating station. The current from the switchboard is received by alternate current converters or transformers by which the potential is raised in the present plant to 1,200 volts. In practice, the transformation would be a much higher voltage, depending upon the distance of transmission. The transmission circuit conveys the current to the receiving station, where it is reduced by transformers to electromotive forces appropriate to the machines to be supplied. The current passes through a marble switchboard in which there are suitable provisions for operating the various machines in the receiving station.

The largest machine in this station is a 500 H.P. two-phase Tesla motor and rotary transformer. This machine is similar in general construction to the generator above described. The alternating current at 360 volts is passed into four collecting rings on the armature. Special connections of the field circuit are made for starting the machine, and when the motor has attained full speed a switch is turned giving the final connections and running the machine as a self-exciting synchronous motor, which maintains the exact speed of the generator by which it is driven, except in cases of extreme over load. The armature of this machine is provided with a double pulley with belts driving a Worthington pump and a 40-light Westinghouse alternating current arc light dynamo. The armature is supplied with a direct current commutator, connected with the same winding, which receives the alternating current, and delivers direct current at a potential of 500 volts. This current is utilized for operating two 30 H. P. street railway motors mounted upon a truck, and also a 60 H.P. direct current motor mounted upon an Ingersoll-Sergeant air compressor. The direct current also supplies a series of direct current constant potential arc lamps. The current from the switchboard is also carried directly to a 60 H. P. two-phase motor and rotary transformer, which receives the current at 36 volts and delivers direct current at 50 volts adapted to electrolytic work, charging of storage batteries, and is at present used for operating the large Shuckert searchlight in an adjoining space. The current from the switchboard also operates a 60 H. P. two-phase Tesla motor of the synchronous type, which is adapted for any kind of constant speed work. In the present exhibit, it is direct coupled to a 45 K. W. slow speed alternator of the constant potential type used for incandescent lighting. Current from the switchboard is also directly utilized for supplying incandescent lamps.

It is commonly recognized that the mechanical design and workmanship upon electrical apparatus has fully as important a bearing upon its successful operation as the electrical design. In fact, in actual experience, it is found that electrical enterprises which have failed, or have been unsuccessful, have been deficient usually in mechanical rather than in electrical elements. It is therefore of especial importance to note the mechanical features of a new system, and to observe whether simplicity and strength and durability are insured Visitors to the present exhibit are struck with the general similarity in construction of the machines employed for widely different electrical purposes. The general form and construction of the large Tesla motor of the rotating field type, the alternate current generator, the alternate current motors, the rotary transformers, the alternating current arc machine, and the constant potential alternator have the appearance of general similarity.

The main castings are two in number. The lower one contains half of the field magnets and the bearings for the armature shaft. This simple form insures rigid bearings for the armature. The upper casting contains the remaining field magnets. The field magnets are made of laminated soft steel plates of high permeability, which are cast into the yoke of the machine. The armature is built of thin disks of soft steel with grooves in the surface for receiving the windings. The armatures are drum wound with, in general, large conductors placed in special heavy insulating tubes through the slots. This construction affords excellent insulation and protection of the wires, and the strains upon the wires, which in case of sudden heavy loads or short circuits may be very great, are transmitted directly to the iron core without chance for slipping or abrasion. In general, no band wires are required. The winding and connections of the armature of the multipolar machines for delivering direct current are such that there are always two, and only two, parts of the winding in multiple. This insures electrical symmetry, which prevents the improper distribution of current in the armature conductors, which would result if there were a greater number of armature circuits in multiple and the armature should get slightly out of centre from excessive wear in the bearings or other cause.

Attention is called to these points of simplicity and solidity of construction because they are so vital to the success of electrical working, and because the general improvement which is constantly being made in the mechanical development of electrical apparatus has been fully utilized in the design of this system. It is much to the credit of the system, and confidence in its success is assured for the very reason that it uses and makes but slight modification in types of machines which have been worked out in practice in other lines of service.

This system possesses characteristics which adapt it to a wide field of service, as it combines the requisites for transmitting power over long distances, and for transforming it into suitable forms for distribution and application to a wide range of uses. The employment of the alternate current transformer permits the use of low potential machines, securing greater cheapness, efficiency and a higher factor of safety than is possible in high potential machines. By the use of alternating current the difficulties in construction and operation, which are inherent to commutators, are avoided on generators and motors. The low pressure of the machine is readily transformed to potentials adapted to great distances. The alternating current supplies two-phase motors of either the rotary field non-synchronous type or of the synchronous type, and the rotary transformer transforms alternating into direct current. The work of this machine is equivalent to that of an alternating current motor driving a direct current generator. The two armatures, however, have been combined in one and placed in one field, and not only is the second machine eliminated, but the output of the single machine is greater than that of the two machines together, and the efficiency is increased and the commutation of a greater current is readily effected. The alternating current circuits can supply therefore constant potential direct current at any voltage, and is available for all kinds of work in which direct current is necessary or is preferable to alternating current. Incandescent lighting may be supplied from the alternating current circuits, and arc lamps may be supplied by direct current from the rotary transformer or from arc machines driven by synchronous motors.

It should be noted that the idea of complication may result from the grouping of several applications of the system with the transmission system proper. The transmission system proper ends with the switchboard and rotary transformer in the receiving station—other apparatus would be located where it may be required for use—distributed over a city or through mills or mines.

The alternating and direct currents at various potentials for these various lines of service are secured from one generator and one transmission line. This is of practical importance both in small plants where it would be impracticable to install different generators and circuits for different kinds of service, and also in large plants where there are numerous generators. In such plants similarity and interchangeability of machines and circuits are of great economy and value in practical service.

Electrical inventors have done their part well in discovering the principles and laws which form the basis for a complete electrical system. Designers and mechanics have taken up these inventions and have developed them and constructed apparatus for practical working, which is now presented to the electrical engineer for adaptation to the various demands for the transmission and distribution of power. He may take up the work with full assurance, as plants are already in operation which place beyond question the practicability not only of general distribution and service, but also of transmission over long distances and at high potentials. The successful installation and operation of a lighting plant for over 100 H.P., using 10,000 volts over a 23-mile circuit, in southern California, is an initial step which covers a distance greater than is required in a majority of the cases in which power transmission is proposed.

This exhibit of the Tesla polyphase system is the mechanical realization of one of the most unique and beautiful discoveries in electricity in recent years.

* Paper read at the International Electrical Congress, Chicago.

Direct Current Dynamos of Very High Potential.

BY PROF. F. B. CROCKER.*

This treatment of the subject is in no sense a formal paper, being merely a note of some experimental results which I have obtained from two dynamos with very high potential, and it is well, I think, to define what I mean by that expression, which is in some doubt. By very high potential I mean from 5,000 to 10,000 volts. Machines of this character have received comparatively little attention, either from scientific experimenters or practical engineers. The speaker has long believed that facts of theoretical and commercial importance might be derived from the investigation of such machines. Considering these machines historically, the first fact that meets our attention is the fact that there exists a general and deeply rooted idea that direct current dynamos of very high potential are not at all practical. This unfavorable opinion is particularly strong in regard to the use of such machines for the transmission of power for any considerable distance; in fact, such a system is considered to be almost out of the question. It is partly with the object of bringing this system into notice—in fact, only that—that I am now reading the paper. The actual historical and practical facts are that the high potential direct current machines were more extensively and successfully operated when the dynamo first came into general use, about 1880, than any other type, either direct or alternate. Furthermore, their number and size have largely increased, and the voltage at which they can be practically worked has been steadily raised until we now have about 60 light arc dynamos of the standard size on large machines generating about 3,000 volts at 10 amperes. Arc dynamos of 90 light capacity are also regularly made by several manufacturers, and 120 or even 125 light machines are built and used. I happen to know of one station where there are four arc dynamos rated at 125 lights, which run every night with a load of from 100 to 105 lights. These machines must have force to generate about 5,000 volts each. No great practical or other difficulty is found in operating arc machines, except that of danger to persons, but this is merely due to the high potential and does not depend very much upon the type of machine or character of current. Nevertheless, when it is suggested to use direct currents in the transmission of power, we are told that nothing over 1,000, or at the most 2,000, volts is at all practical. Why this discrepancy between the 5,000 volts which are practically used in arc lighting and the 1,000 or 2,000 volts that are considered the limitation of such machines for power transmission? Perhaps the first answer to this question would be to say that the current is limited, that when you have 5,000 volts you cannot have more than 10 amperes, and if you want more amperes you must have less volts; consequently the number of watts, which, of course, is the entire question in power transmission, is limited. For example, the machines which I cited and which are in practical and successful use are 5,000 volts electromotive force, generate only 10 amperes, and consequently have a capacity of 50 kilowatts, which is a small power, comparatively speaking, for power transmission, but is sufficient for ordinary arc lighting circuits. That, of course, is a fairly good explanation of why such machines are not applicable to power transmission, but is there any such limit as 10 amperes to the current? I myself always look with very much suspicion and doubt upon any such arbitrary limit as that. Experience has shown me that those arbitrary limits are usually imaginery. I would like to cite one simple case to show exactly what I mean. I can remember when, in connection with a design for motors, small motors, I desired to use drop forge for the field magnet. I was told that the largest drop forging that could possibly be made was two pounds, and the best drop forger in this country would not undertake to make a larger one than that. I now have no difficulty in getting drop forging to 90 pounds, and the percentage of increase in weight per annum has been about 100. Now, that will not go on indefinitely, of course, but the limit of two pounds was purely arbitrary. No such limit existed in that case, and I doubt if any such limit exists in this case. I do not believe that nature decided that it would be impossible to generate currents of more than one absolute unit, and that it happens to be that of 10 amperes with a high potential direct current machine. Now, it is a fact, however, that should be added to this historical consideration of the subject, that numerous attempts have been made to employ such machines for power transmission and other purposes, and it cannot be said that those attempts have been successful; in fact, it can be said that they have been unsuccessful, but there again we have merely the negative of it. That same statement could have been applied to the steam engine for several hundred years, and it has only been true of the direct current machine for say ten years, consequently the case is by no means hopeless. But nevertheless numerous attempts have been made by competent persons, involving the expenditure of many thousand dollars, and that is a fact that cannot be ignored and should receive proper consideration, but it by no means puts the use of direct current machines of very high potential—over 5,000 volts or about that—out of the question for power transmission or any other purpose.

Now, when we come to the actual construction of such machines, and that is really the only substantial point that I can bring before you, I have actual results, although I cannot say that there is any particular feature of such machines which is radical or which will insure their successful operation. The first point, of course, is insulation. That must be above suspicion. The ordinary limit of one megohm of insulation is simply nothing for such machines. One megohm of insulation resistance, with a voltage of 10,000, would give 1/100 of an ampere and 100 watts; consequently the machine insulation would be rapidly heated up and destroyed; therefore you must realize that a megohm, or even several megohms, is no insulation at all for such a machine. It should be at least 1,000 megohms.

The next point is the commutator, because although the commutator might be considered the first point, as a matter of fact we must have the insulation before we can operate the machine at all, even for a few moments. The commutator, of course, must have a number of sections. It must have a considerable thickness of mica insulation between the bars—more than is ordinarily employed; I should say a full 1-16 of an inch. That does not sound very large, but as a matter of fact it is large, from 1-16 to 1-8 of an inch between the bars. On the end of the commutator, where you get much more than the ordinary voltage between the bars, you require very much more thickness of mica insulation or some other insulation than is ordinarily given. I should say that at that point we should have an actual thickness of insulation of a quarter of an inch, and if possible the surface distance should be increased by having the insulation project.

The next point is the material for brushes, and I have found in that particular feature the most peculiar and important differences. In the first place, I consider that it is impossible to run an ordinary mica insulated commutator with copper brushes at that potential, the reason being that this film of copper which is worn off of the copper brushes by the mica is a sufficiently good conductor at that electromotive force to carry many watts of current. At an electromotive force of say 500 volts, comparatively speaking, for instance, the ordinary railway generator, we have no such difficulty, because even if we use common brush connections the film of copper that is rubbed on to the surface of the mica would not carry sufficient watts to cause any trouble, but at 10,000 volts, with a total electromotive force in the neighborhood of 100 volts between the bars, the amount of copper even although it is an almost infinitesimal film is sufficient to carry, as I say, many watts of current.

Now, I have found that in a high potential, of only 5,000 volts, which I have experimented with, copper brushes could not be used for half a minute; that the copper was worn off on that mica and immediately produced a ring of fire all around the commutator. Naturally one would use carbon brushes in such a case, because the current is very small, comparatively speaking. I simply state the fact decidedly that you cannot use copper brushes for the reason given. When you come to the carbon brushes, I have also found that the hardened carbon is better, for the reason that it does not produce a deposit or layer of carbon on the commutator to produce the same effect which the copper does, but not to the same degree, because carbon is a much poorer conductor than copper; therefore carbon brushes, with a comparatively small area of contact and a fairly good pressure—not very great but sufficient to insure good contact—seem to be the proper working conditions.

Now, the machines I have actually constructed are two. One was a small machine of one horsepower capacity, and the armature was a fluted armature. Some persons may think that is exactly wrong, but the results do not seem to show that it was. The fact that it was a fluted armature is one reason why I was successful with these machines. I will not say that. I simply say that it may be, because I think that heretofore machines of very high potential have not been made with fluted armature. It was of the ordinary Crocker-Wheeler type, and very perfectly insulated with mica and wound with double silk covered wire. The potential of that machine was intended to be 5,000, and I have succeeded, by slightly raising the speed, in getting 5,500 volts out of it. It had only 32 commutator bars. That is the remarkable fact, with 5,500 volts, 32 commutators, say 350 volts difference of potential between the bars. I was told, I remember, a good many years ago, that you could not have more than 19 volts. I could never understand why they gave us 19 instead of 20, but such was the case. Now, this certainly shows that any such limit as that does not exist, but that machine is not, of course, a practical machine, but it did run for hours at 5,000 volts, for an hour and a half at 5,500 volts, and several times without any difference. Now, that simply shows the minimum number of commutator bars that you can use, I should say. Now, as to the current possible to get from that machine, of course that is small. As soon as you draw a current from a machine of that small number of commutator bars, there would be a tendency to stop the working, and that, of course, produces a ring of fire around the commutator.

The next machine, which is a much more practical machine, was of five horse power capacity, and designed to generate 10,000 volts. It did generate 10,000 volts at a little below the calculated speed, strange to say, and gave 11,000 volts at about the speed it was designed for, which was 1,800, not a high speed. This machine had 108 commutator bars, a much more practical number for such a voltage. The current of that machine was intended to be between three and four tenths amperes, which gives about its capacity. It must be remembered that these machines did not give their full capacity, owing to the fact that the wire is extremely small, and therefore the percentage of copper in the winding is small. The winding is largely made up of silk, consequently the capacity of the machine is reduced by that fact. That is inherent in any machine wound with extremely small wire. The current actually obtained from these machines is in the neighborhood of their rated capacity.

---

* Address before the International Electrical Congress at Chicago.

It would be unfair to myself and to you to deny the fact that there is a spark when you approach the current capacity of the machine, and I think at the current capacity the spark would be too great. I have approached this 11,000 volt machine, and am a little bit afraid of it, to tell the exact truth, and I have not drawn the full capacity from it, but at about half its capacity it begins to spark, not badly, and a little above that it sparks a little more, and I should imagine it could not be run at its full nominal current capacity. The machine has only been recently finished, and since it was finished I have only had a few days to experiment with it, so I cannot give you full facts on it, as I did not want to rush in and break it down the first day, because I wanted to have two or three days with it. I might say that both machines broke down one or more times before I succeeded in getting them running, but that was simply due to inadvertence or accident. It was not inherent at all. There was some palpable error in their constructing. In one case the mica insulation in a slot was defective through the laziness of the winder. The proper way, of course, is to have that entire slot filled with a number of thin pieces of mica bent into the shape of the slot. It is impossible to bend a thick piece of mica that way. All that is necessary is to subdivide it into a number of pieces, and bend it into the form and put it into the slot, and get any degree of thickness desired. About one millimeter of insulation is sufficient, provided it is made up of mica which is bent into the proper form and not simply joined.

Now, I intended to have had this machine here, but I anticipated that it would not be a particularly good place to show it, and in the hurry and confusion of the Congress I thought that it would probably ruin the machine and would not do anybody very much good, so I would simply announce the facts, and probably later I will publish a more detailed description.

There is probably one point that strikes you as peculiar, and that is the very high internal resistance of such a machine. This machine has something like 1,500 ohms internal resistance. Now, as a matter of fact that is perfectly normal. The voltage is so high and the current is so small that an armature resistance of 1,500 ohms is perfectly proper. In that connection I might argue that of course the proper or allowable armature resistance varies as the square of the electromotive force with a given number of watts. The precaution necessary in operating such a machine is to prevent the spark from starting. It is like the smoke nuisance. The way to get rid of the smoke is not to produce it. That prevention of sparking in the first place is secured, as I say, largely by the use of hard carbon brushes, smooth, hardened carbons of fine grain.

Another point is, the tension of the frame must be kept half-way between the terminal electromotive force. That is an important point. My friend, Mr. Bradley, who has also advocated the use of these machines for power transmission, has a system of this sort where he purposely and positively keeps the potential at the proper point half way between the terminal force. By that I mean, if the total electromotive force is 10,000 volts between the two brushes, that the frame should be 5,000 volts to a potential between it and the positive brush, and the same way with the negative. If that frame was grounded on the negative brush or connected with the negative brush, more properly speaking, you would get the total difference of potential at that point or at the commutator, tending to produce a ground, and the difference between 10,000 volts and 5,000 volts is very material in producing a ground. It is almost necessary to keep that potential at that point. Now, in regard to how to keep it there, as I say, Mr. Bradley has a system by which he positively does it, but if the machine is highly insulated it takes care of itself. I have measured these machines when in proper working condition, and the potential of the frame will be almost exactly half way between the terminal potential, within two or three per cent., and that is quite remarkable. The rubbing, which of course occurs even in the insulation, is 1,000 megohms, which will produce a balance, and if the general insulation is uniform it will fall about half way between. That is quite an interesting fact. I may say that these measurements of the voltage were made by an electrostatic voltmeter of the Sir William Thompson pattern, made by White, of Glasgow, and compared at the lower voltages with the Weston voltmeter. It seemed to be in perfect working condition, and gave very satisfactory results. Nothing could be more convenient and satisfactory for the purpose, because an electrostatic voltmeter has the advantage of not carrying any current and producing no drop or trouble of that kind. I think there is no other precaution that I have found to offer.

As to the applications of these machines, I would say that the purposes to which I have applied them have been ordinary experimental work. For example, one of these machines at 3,000 or 4,000 volts will run a Geissler tube very beautifully. It will produce any other of the so-called electrostatic effects, that is to say, effects produced by very high potential in small quantities. It will, for instance, act very much like an electrostatic machine or a friction machine. It will cause one of these electrical flyers to revolve. In other words, you can get all the electrostatic effects similar to this potential from an ordinary frictional machine.

Another purpose to which the machine is applicable is testing of insulation, and in fact that is one purpose for which I made it. It is a very good way to test insulation. You will immediately ask, why not use a high potential transformer as being more convenient and not having a commutator?

I answer that by saying that I do not think that is the same test. If the wire is exposed to a direct current strain, I do not think an alternating current test is proper. If a wire is subjected to a direct current strain, it should be subjected to a direct current test. If it is subjected to an alternating current strain, it should be subjected to an alternating current test. That is simply my idea. The other application is, of course, power transmission, and that will be discussed hereafter, and I would say that of course it is not necessary to have the total voltage generated by one machine. In any plant no one dynamo should constitute more than a comparatively small fraction of the total plant, and if you have five dynamos in a central station or power transmission station, there is no reason why they should not be connected in series as well as in parallel, and if you want five machines, as I think you do, in order to guard against the trouble from breakdowns, five to ten machines, then you can easily connect them in series and subdivide the voltage just to that extent. Each machine can generate a few thousand volts, two to five, and you could get the total voltage by the proper series connections of several machines.

On the Carrying Capacity of Electric Cables, Submerged, Buried or Suspended in Air.—III.

BY A. E. KENNELLY.*

CARRYING CAPACITY OF CABLES IN AIR.

Although the condition of an active cable supported in air is only a special case of the general heating of aerial conductors, yet it merits separate consideration owing to the comparatively high thermal resistance of the insulating covering in such cables, and the leading influence of this resistance upon the carrying capacity.

The current strength that will elevate the temperature of this conductor θ° C. when supported horizontally in air is

$$C = \sqrt{\frac{\theta}{P\left(S+\frac{1}{\varepsilon}\right)}} \quad . \quad . \quad . \quad (11)$$

where ε is the total emission of heat from the external surface per linear centimeter, by convection, radiation and wind, per degree centigrade of temperature elevation there existing. As the temperature elevation of the sheath will in practice be less than 20° C., ε may be taken as constant within that range, and as being expressed by the equation

$$\varepsilon = 0.00111 \times O + 0.00175 \quad . \quad . \quad (12)$$

where the first term on the right hand refers to the radiation, O being the external circumference in cms. and the second term to convection. The cable is supported in still air. These constants appear to satisfy the observations very fairly. Also $\frac{1}{\varepsilon}$ may be regarded as the equivalent thermal resistance of the air round the cable under these circumstances, corresponding to the resistance G of the soil in a buried cable.

Example: The cable previously considered, instead of being buried, is supported in still air. Required the limiting current. Here O = 3.23 and $\varepsilon = 0.005335 \quad \frac{1}{\varepsilon} = 187.4$.

The total thermal resistance is

$$81.36 + 187.4 = 268.76,$$

and

$$C = \frac{5}{\sqrt{0.000009417 \times 268.76}} = 99.42 \text{ amperes.}$$

It appears that $\frac{1}{\varepsilon}$ is greater than G in most cases that are likely to occur in practice (exceptions occur in heavily insulated cables), so that the thermal resistance to the escape of heat from a cable is usually less when the cable is buried than when supported in still air. Consequently the temperature elevation will be the greater in the latter case for a given current strength. Also, if a cable is first supported in the air of a vault, and then enters a trench, there will be no overheating of the buried portion by load, if it is known that the buried portion is within the safety limits of temperature elevation, and the temperature of the sheath in the buried portion will be lower than the temperature of the sheath in the vault, assuming that the normal temperature of the soil and of the vault are equal.

THERMAL RESISTIVITIES.

Comparatively few measurements have been made of the thermal resistivities of bodies. They are known to be functions of the temperature of the substance. There is also reason to believe that good heat conductors conduct better, and good heat insulators insulate better at low temperatures,† in analogy to the electrical properties of similar materials. In the absence of better information the resistivities taken in dealing with these cables are assumed to be constant throughout the range of temperature employed.

* Read before the Association of Edison Illuminating Companies.

† Professor Forbes l.c., also Everett's Units and Physicall Constants Article "Heat."

Appendix III gives the computed limiting current strengths of Siemens cables as manufactured in 1892 at the Schenectady Works, from measurements of the dimensions of samples, and from the constants arrived at by measurement and alluded to above.

APPENDIX I. PARTICULARS OF MEASUREMENTS MADE ON SAMPLE SIEMENS CABLES.

Four samples of Siemens cable, each about thirty feet long, were employed, viz., No. 12 B.& S., No. 6 B. & S., 80,000 cir. mils and 200,000 cir. mils. The two last had stranded conductors.

The insulator was jute soaked in special compound. The sheath was a cold rolled leaden tube fitting over the insulator.

Each cable was tested three times, once in flowing water, once supported in still air, and once buried in the ground.

In the first test the cable occupied an iron pipe 880 cms. long and 3.3 cms. internal, 4.1 cms. external diameter, resting upon the ground upon a slight incline. Short right angle pieces were attached vertically to the ends of the pipe, and water was kept flowing through this pipe with sufficient velocity to maintain the temperature of the water within one degree centigrade at ingress and egress. The mean of the water temperatures at the two ends was assumed to coincide with the mean temperature of the sheathing. Measured currents were delivered through the cable, and the resistance of the conductor measured by differential galvanometer in comparison with a platinoid standard. The increase of resistance in the conductor covered by the pipe gave by Matthiessen's table of temperature coefficients the temperature elevation of the copper. The electrical connections were practically the same as those described and illustrated in the report upon the heating of conductors submitted at the Convention of Edison Illuminating Companies at Niagara Falls in August, 1889. From these temperature elevations, measured current strengths, and the dimensions of the cable, the thermal resistivity of the insulating material was determined.

In the second test, the cable was supported in still air, the remaining conditions being otherwise unchanged. The temperature of the sheath was measured with thermometers as a check upon the computed values.

In the third test, all four cables were buried at a depth of 76 cms. in sandy soil and parallel to each other in the same trench, the axes of adjacent pairs being 16 cms. distant. The length of each cable resting on the bottom of the trench was 720 cms., 90 cms. being required at each end for the ascent to the surface of the ground. Pressure wires were soldered to the conductors at the upward bends, so that only the resistance of the lengths at the full depth was measured. The same method of testing was employed throughout. The approximation to final temperature elevations was rapid in the water covered samples, the increase in resistance with a given current being almost inappreciable after fifteen minutes' application. It was somewhat delayed in the tests in air, twenty-five minutes being generally required, and with the buried samples readings continued to advance until forty or fifty minutes after application of load.

APPENDIX II. DATA FOR CONSTRUCTING A DIAGRAM OF ISOTHERMAL SURFACE SECTIONS.

Let D be the depth of the cable's axis in cms.
" R " the external radius of the cable sheathing (cms.)
" y " the depth of the axis of an isothermal cylinder (cms)
" x " the distance at which the isothermal cylinder intersects the horizontal plane through the cable axis (cms.)
Let a be the radius of the isothermal cylinder (cms.)
" v " the ratio of the temperature on the isothermal to the temperature at the external surface of the cable.

Then

$$a = \frac{2\,D\,B}{B^2 - 1}$$

$$y = D\,\frac{B^2 + 1}{B^2 - 1}$$

$$x = \frac{2\,D}{\sqrt{B^2 - 1}}$$

Where

$$B = \varepsilon\ v\ \log_e\left(\frac{2\,D}{R} - 1\right)$$

Example: D = 100, R = 5, find the isothermal of half sheath temperature elevation, or v = 0.5.

Here

$$B = \varepsilon\ 0.5 \log_e 79 = 8.888$$

$$a = 22.79 \text{ cms.}$$

$$y = 102.6 \text{ cms.}$$

$$x = 22.65 \text{ cms.}$$

APPENDIX III. COMPUTED SAFE CARRYING CAPACITY STANDARD SIEMENS CABLES MANUFACTURED AT SCHENECTADY WORKS IN 1892. (Capacity in Amperes.)

Size.	Water.	Soil.	Air.	Water.	Soil.	Air.	Water.	Soil.	Air.	Water.	Soil.	Air.	Water.	Soil.	Air.

In reference to the above table it may be pointed out that additional carrying capacity of a cable when in water over that it possesses when in air can seldom be availed of for the reason that a cable passing through water will usually have at least a short length in air or soil, which portion would become overheated if the length in water were worked to full capacity.

For the buried cables, a temperature elevation of 12.50° at the sheathing surface has been allowed.

(Concluded.)

Note on the Variation of Capacity of Insulated Wires with Temperature.

BY HERMANN S. HERING.*

While making some tests of insulated wire for the Chicago Electric Company, I determined the capacity, resistance and electrification at various temperatures, and found that there was a decided variation of the capacity with the temperature of the wires. The samples of wire tested were of Nos. 12 and 16 B. & S. gauge covered with vulcanized rubber, the patented process of this company, and invented by Mr. H. B. Cobb, of Wilmington, Del. The radial thickness of the insulation was about 1-16 inch. In two of the samples furnished, Nos. 3 and 5, the insulation was loose upon the wire, and in Nos. 1, 2 and 6 it was tight.

By referring to the diagram it will be observed that the curves are distinct and have a definite shape, and that there is a decided increase of capacity within the usual ranges of temperature met in practice.

All the tests were made in the same manner, with the same instruments and with all possible errors eliminated. Readings were taken after the wire had been charged twenty seconds.

The curves represented by solid lines were made during an immersion of the wire of from five to ten days. Those represented by broken lines were made after an immersion of from twenty to thirty days. It will be observed also that the capacity increased slightly with the length of immersion, and that the capacity of samples Nos. 3 and 5, whose insulation was loose, not only had a smaller capacity per mile than samples No. 1, 2 and 6, whose insulation was tight, but also had less variation within the same ranges of temperature.

The cause of this increase of capacity with the increase of temperature is not easily explained unless the expansion and contraction of the insulation acts inwardly as well as outwardly, but yet that does not offer an entire explanation. I thought at least that the results would be interesting, notwithstanding that I had no satisfactory theory with which to explain them.

Current Items.

A short time before Dr. Charcot died he said in a lecture that semi-scientists had for more than fifty years ridiculed the idea that the full of the moon was a dangerous time for mad people. Better informed men are coming back to the old-time notion, said Dr. Charcot, as the result of increased learning on the subject of earth tides, similar to the oscillation of sea tides.

The Elektricitats Aktien Gesellschaft of Nürnberg announce that they have completed a new installation for lighting up the stages of theatres. It admits of modifying the degree of intensity of the lamps at pleasure, and of varying the character of the light by the introduction and removal of colored lamps. White, red and green lamps come into use, and the "Regulator" gives the facility of causing two groups of lamps to burn simultaneously, either white and red, white and green, or red and green. It is possible to produce the following changing effects: Bright daylight passes into evening twilight, and this again into a nocturnal effect with moonlight. This again gives place to a red morning dawn, which is succeeded by daylight. The invention has been brought into successful action in various theatres in Germany, Denmark and Russia.

The N. Y. State Street Railway Association.

The N. Y. State Street Railway Association holds its annual convention at Rochester, beginning next Tuesday.

There should be a liberal attendance from this section. The ride through the State at this time of the year, on the New York Central Railroad, is a pleasure, and the proceedings of the convention are sure to be up to the standard.

Long Distance Transmission. The question of long-distance transmission of power is one of the most prominent ones which confronts the electrical engineer to-day. At the introduction of electricity on a commercial scale, electric lighting occupied the minds of electricians almost exclusively, and at that time the method of distribution of current from a central station was the problem which engaged universal attention, and arguments were heard favoring either the two-wire or the three-wire system of distribution, or the alternating current against the direct current, or vice versa. At first the direct current had almost a monopoly of the lighting field, but as the alternating current became perfected in its methods of distribution its merits were gradually recognized, and it has since become a prominent factor in electric light distribution.

When the practice in electric lighting work had assumed a tolerably definite character the electric railway problem was launched, and for a time the developments in this direction almost overshadowed electric lighting. Here the question was confined to details of the direct current system, as at that time, and even at present, no motor suitable to this class of service had been invented for alternating currents. The controversy in this case was confined to the methods of regulation on car motors and the character of the overhead and track construction. Patents on almost every conceivable point in electric railway work were taken out, but these did not appear to obstruct the advances in this line in the least. Every manufacturer of electric railway apparatus eventually came into possession of fundamental patents which were infringed by every other manufacturer of these goods, and the business in this way settled down to a practically common practice, and the price of car equipments fell from three thousand dollars and more down to fifteen or sixteen hundred dollars under the salutary effects of competition. At present the method of distribution and the track wiring are almost identical in all electric railway systems, and the principal difference lies only in the design of the machinery.

What might be considered the third era in the application of electricity is just coming prominently in view, viz., the transmission of power. This phase of electrical work, although the simplest theoretically, is likely to prove the most difficult to put into actual practice. It is impossible in the present state of the science to prescribe either a direct, simple, alternating or multiphase current as a general solution of long-distance transmission, and it is not improbable that each of these systems will find application in various places, according to their individual requirements.

The multiphase current, being the latest development, is at present attracting a monopoly of the attentions of electrical engineers, and at first sight the peculiar properties which it possesses make it specially adapted for both lighting and power, but multiphase motors are as yet comparatively new, and the test of time is needed, as well as a more extensive use, to determine the efficiency and practicability of multiphase systems. The simple alternating current, while giving a good efficiency, is handicapped for the want of a self-starting motor under load, which puts this system at a disadvantage for a general distributing plant. It has been successfully operated, however, in the case of mines and other places where a special starting device was used for the motors.

The direct current system has been largely lost sight of in discussing long-distance transmission, but there are many engineers who believe that high tension direct-current machines will, nevertheless, play an important part in long distance work. For large motors and street railway work the direct current is as yet almost indespensable, and there can be no question but that much higher working pressures than are now in general use are perfectly feasible. In an address by Prof. Crocker, printed elsewhere, he points out that raising the voltage of these machines to 5,000 and even 10,000 volts is quite possible with sufficient care in the matter of insulation.

The commutator is of course the great bugbear in machines of this sort, and in general the trouble at that point will prevent the use of a single machine of such a high voltage as would be required for a very long line, but connecting several machines in series would largely overcome this difficulty.

In the matter of transformation the direct current is still at a disadvantage compared with the alternating, and it is obviously impossible to use a pressure of several thousand volts for the service of small consumers. For local distribution the use of direct current transformers would be imperative, but these dynamotors can be built to reach an efficiency of ninety per cent. or more, and in this way a certain proportion of the current could be economically distributed for small customers.

While the voltages mentioned seem at first sight to be impracticable, it must be remembered that in arc light work sixty and eighty light machines are in general and successful use generating from three thousand to four thousand volts, and while in most places alternating and multiphase currents will, perhaps, be found the most practical, the advantages of a direct current for many kinds of work render its application to long distance transmission worthy of more study and experiment than it has yet received.

······o······

MR. CLARK confessed to having paid Ashton $1,200. Ashton says it was over $2,000. But admitting that it was only $1,200, where did the money come from? We suggest that Mr. Twombly, who cannot take kindly to this kind of "business," look up the records, and find out who passed the bill.

······o······

THE PITTSBURG trial must have a wholesome effect in one particular. Young men will no longer feel it an honor to be delegated by Mr. Coffin to do foul work. It should be a warning to all the "special agents," etc.

A Humiliating Episode. There can be but one feeling among thoughtful men in regard to the revelations in the blue-print case at Pittsburgh, a condensed report of which is printed in another column. The electrical trade has been disgraced, the cover has been lifted from a sewer of filth, and we know that Electricity voices the wish of every decent man in the business in expressing the hope that there will be no further trial of the three defendants who have just been saved from the penitentiary through a disagreement of the jury.

It seems to us that the object of the proceedings has now been fully attained. The jury has disagreed, true enough, standing eight to four for conviction, but notwithstanding that the defendants have not been convicted before the law, they have been thoroughly convicted before the bar of public opinion.

No man in this trade doubts to-day that the General Electric Company, meeting in the Westinghouse Company a competitor with which it was not fitted to cope fairly, resorted to conspiracy, bribery and theft to obtain information from the factory of its rival, with the immediate object of securing thereby certain specific contracts. These contracts it did not get.

Any further proceedings to be justified should be against the prime mover in the conspiracy, the chief culprit, Mr. Charles A. Coffin. At present it seems that he cannot be reached. To whatever depths Mr. W. J. Clark descended in his mistaken loyalty to his chief, whatever be the measure of contempt which Mr. Mead's part in the matter deserves, the impressive and lamentable fact remains that a second trial of the three defendants, even though resulting in a conviction, would be but the punishment of the servant for obeying the commands of the master.

Mr. C. A. Coffin dare not go to Pittsburgh and testify that he did not give Mr. Clark exact verbal instructions as to the information wanted, nor that he did not tell him the amount of money which he might spend in obtaining it, nor that the expense sheets embracing the amounts of money so paid were not passed by him.

Until the author of the infamy can be brought to book it would avail little to have Messrs. Clark and Hamilton suffer further. Already the reputations of half a dozen young men have been blackened; they have lost the respect of even their best friends; they must suffer under the stigma until they have lived it down by years of correct conduct. They have been punished enough.

Let us cover up the stench, in the full assurance that Mr. Coffin will not soon be able to find other young men ready to sacrifice their manhood in his service and to protect him at the expense of their own reputations.

……o……

Mr. Coffin is welcome to all the satisfaction he can extract from the fact that his part in the blue print steal was only a misdemeanor, and not an extraditable offence.

……o……

The industry of stealing blue prints has met with a permanent set-back.

Municipal Lighting Plants. We print elsewhere in this issue an interesting letter recently sent by one of our larger manufacturing companies to a prospective customer.

Much has been said both for and against municipal ownership, but the subject is not exhausted, and is not likely to be very soon. New municipal plants are continually being installed. Many of those already installed are successful, and, in spite of adverse criticism of the electrical papers, the idea seems to be growing in popular favor.

Mr. W. H. Preece, in a recent letter to the Governor of Malta, referring to some English municipal plants, points out that while capital expended by the vestry of St. Pancras and the Corporation of Brighton has exceeded the original estimate, it is because, "owing to the unexpected and rapid success of the industry in both places, the increased demand for light has necessitated increased plant and therefore expenditure. In each case a commencement was made in a very small fraction of the estimated area to be served.

"In Huddersfield, before the first contract is completed and before a single lamp is lighted, the Corporation have found the demand for light so far in excess of their anticipations that they have had to increase their plant and their capital expenditure.

"I cannot too strongly point out that in England there has been no single instance of financial failure when Corporations have taken the matter in their own hands. The rates have never once been called upon to supply any deficiency.

"Success in all instances has been assured, and the rate of growth of the business has exceeded the wildest anticipation."

……o……

The Chief Culprit. Let it not be forgotten that all the bills for the corrupt expenditure of money in the blue print steal, as also in the dozens and scores of bribery cases not yet uncovered, were necessarily passed for payment by a high official of the General Electric Company.

Let us ask ourselves who could have passed them.

Not Mr. Beves, the treasurer, nor Mr. Ord, the controller, not Capt. Griffin nor Lieut. Greene, for large amounts, as their authority is not broad enough; surely not Mr. Peach, who is the soul of honor; not by Mr. Garfield alone, because he never wiggled his thumb without Mr. Coffin's direction. Who is left? In all reason, no other man than Charles A. Coffin could be cognizant of what this money was spent for, or could O. K. the corrupt expense sheets for payment.

……o……

The events of the past three weeks are all the exemplification which Electricity needs for its continued attacks on Trust methods. That we have not seen fit to disassociate the methods from the man, is already admitted by most of our critics to have been fully justified by our evident knowledge of the man and his methods. The end is not yet.

"There are lawyers enough in the electric conspiracy case to account for the present depression in the price of electric stocks."—*Pittsburgh Times.*

This was intended as a joke, but contains too much truth to be funny. The General Electric Company's legal expenses for their first fiscal year would have more than paid two quarterly dividends on the common stock on an eight per cent. basis. If the large manufacturing companies in years past had pushed their own businesses and refrained from pushing so many foolish patent suits, the lawyers would be poorer but the trade at large would be far richer.

……o……

We are in receipt of a long communication from Miss A. E. Post, which is chiefly an argument in support of the claims of Mr. Adolph Berrenberg for the invention of the mechanical vacuum pump. We do not think the readers of Electricity are interested in this subject, and consequently cannot publish the communication.

……o……

The retirement of Mr. Paul T. Brady from the service of the General Electric Company is but natural. Under present conditions the clergy of Central New York cannot be worked to invest in General Electric, and it is commonly understood that work of that nature was Mr. Brady's specialty.

……o……

We have learned incidentally that one of the largest of the closed-down lamp factories will be opened for business early in November next, proceeding on the assumption that the Edison patent expires on November 10.

……o……

About ten weeks after Electricity announced the fact, our old fogy contemporaries, the *Electrical World* and the *Electrical Engineer*, learned that there was a rupture between the Fort Wayne and General Electric Companies.

……o……

Mr. C. A. Coffin ought to feel highly gratified over some recent events. He has seen his employees at Pittsburgh sacrifice honor, friends, and future prospects rather than expose him, the author of all the villany.

……o……

As predicted many months ago in Electricity, Mr. H. M. Whitney has retired from the management of the West End Road.

……o……

The law presumes that when a man testifie that he is a villain he is to be believed in that statement but in nothing further.

……o……

The news of the day can only be found in one electrical paper, and that is Electricity.

Execution Against the A. B. C. Company.

Deputy Sheriff Finn has received an execution for $16,549 against Alexander, Barney & Chapin, in favor of Patrick Gray on assigned claims of Luke A. Burke. The business was started by P. H. Alexander, of Hyde Park, Mass.; General C. H Barney and Charles B. Chapin, of Hartford, Conn. They incorporated it in November, 1890, with a capital stock of $100,000. Luke A. Burke, a builder, obtained control of the company in 1891, becoming vice-president, and Messrs. Alexander, Barney and Chapin retired from the concern.

The Rape of the Blue Prints.

Three of the Indicted Men on Trial at Pittsburg.

The Jury Disagreed—Summary of Proceedings.

On Monday, September 4, in the Court of Quarter Sessions at Pittsburg, three of the indicted men in the much-talked of Blue Print case, Messrs. W. J. Clark, Morris Mead and M. H. Hamilton, were placed on trial. They were charged with conspiring to cheat and defraud the Westinghouse Electric and Manufacturing Company of certain letters, writings, tracings, etc., on the 18th day of February, 1893. Information was made May 5, 1893, and a true bill was found June 6, 1893.

The blue prints, etc., were procured for the General Electric Company, under orders from Mr. C. A. Coffin, president of the company, who was also indicted, as were Messrs. E. W. Rice and W. H. Knight, of the Lynn Works. None of the latter has yet been tried.

The attorneys for the defence were Lyon, McKea & Sanderson, Thomas M. Marshall and John S. Robb, of Pittsburg; W. S. Hamilton, W. J. Jenks, W. B. Whitney and W. B. Putney, of New York, and E. M. Bentley, of Boston. Dalzell, Scott & Gordon and D. F. Patterson, of Pittsburg, and C. L. Cravath, of New York, assisted District Attorney Burleigh in the prosecution.

THE CASE FOR THE PROSECUTION.

Mr. D. F. Patterson in opening for the prosecution said: The prosecution would be able to show these defendants had conspired together to cheat and defraud the Westinghouse Electric and Manufacturing Company. He dwelt at some length on the development of electricity and the necessity that all the plans and ideas of promoters of electrical devices should be protected from the inspection of rivals. The purpose of this alleged conspiracy, he said, was for the unlawful and dishonest purpose of securing from the Westinghouse Company plans and blue prints to aid the General Electric Company in bidding on certain contracts for which the two companies were rival bidders. He said the results of the superior genius of the Westinghouse Company had been corruptly secured by the defendants for the benefit of its rival, to the great advantage of the General Electric Company.

ASHTON'S TESTIMONY.

H. F. Ashton was the first and chief witness for the prosecution. He was on the stand the greater part of two days, and testified in part :

"July, 1893, I was employed by the Westinghouse Company. This lasted till January, 1893. From September 1 last I was also employed by Morris Mead and W. J. Clark, of the General Electric Company. I first mentioned the matter to Mr. Mead. He told me to stay with the Westinghouse Company and also work for the other person. The other person was W. J. Clark. I first met Clark in Youngstown, Ohio. Mr. Mead was with me. I had some sketches with me which I gave to Mr. Clark. The sketches were specialties being gotten up by the engineers of the Westinghouse Company. I made the sketches. I had access to all the specialties. Before I met Clark I had copies of voltmeters, etc. I gave Mr. Clark all the information I had. I gave him among other things the plan for the new lamp Mr. Westinghouse was working on. Mr. Clark said he wanted me to get everything I could from the Westinghouse Company for the use of the General Electric Company, plans, drawings, estimates, drawings and plans of new and proposed inventions. I gave him about fifteen sketches. Mr. Mead engaged me to get these sketches. He told me to get copies of all new ideas the Westinghouse people were working out at that time."

Mead paid his expenses to Youngstown and showed him two hundred-dollar bills, one of which he gave him Mead also told him that he would be put on the pay roll of the General Electric Company at $150 per month and expenses. He got the money regularly through Mead, who took $25 per month as a commission. He said he got about $2,000 altogether out of it, clear of expenses.

Ashton, continuing, gave detailed accounts of meetings with Mead, Clark and Hamilton, the defendants, at which he gave them blue prints, sketches and other information. These meetings occurred in Pittsburg, New York and Boston. Among the important matters communicated to the General Electric Company were the Westinghouse plans and estimates for the World's Fair contract, the big Niagara Falls electric machines and a Sacramento, Cal., contract. He bribed an office boy to steal one of the new stopper lamps, then being perfected. This lamp he gave to Mead, who delivered it to Hamilton. It exploded while being unpacked at New York and he had to bribe a boy to get another, which was delivered safely. He also got plans of the direct and the alternating current generators and motors, and of various other Westinghouse machines, some of which were entirely new and had not been patented. He bribed the office boys to steal the prints and articles he wanted, because he said he had had a consultation with Mead, and they decided it would be the safer way. He identified the secret code used in carrying out the plans, and he said it was in the handwriting of Clark.

"Mr. Mead furnished me with the code. I saw a similar one in Mr. Hamilton's room in New York. I destroyed some of the telegrams, but kept some others I received."

A number of letters from Hamilton to Mead were identified by the witness.

"May 1, I was at the works of the General Electric Company and met Mr. Knight in his office. While there I saw, in Mr. Rice's office, some of the blue prints I had taken from the Westinghouse Company and delivered to Clark and Hamilton. When I was there the first time Mr. Rice took the blue prints I had furnished from the drawer where I found them on the last visit. I identified them as the ones I had obtained, because when I made them I numbered them and could positively identify them. There were about fourteen of them."

OTHER TESTIMONY FOR THE PROSECUTION.

Frank Carey was called, and he said he was 18 years old. Up to May 5, 1893, he worked for the Westinghouse Company. He made blue prints and later drawings. He knew Ashton since June 1892. "I gave Ashton some blue prints of the new motor and switchboard last December. They belonged to the Westinghouse Company. Mr. Ashton asked me to get them. He asked me to get blue prints of the World's Fair job, the noiseless motor and others. He gave me $14. I gave him eight He was at the Electric Club. He said if he wasn't there to deliver them to Morris Mead. I was introduced to him by Mr. Ashton. I had no authority to take these blue prints."

Charles Christian—I am 17. I worked for the Westinghouse Company till May 5, 1893. I traced. I know Ashton, he and I worked in the same room. I met Morris Mead in February, this year, in his office. At that time I gave him two blue prints which belonged to the Westinghouse Company. I was sent there by Mr. Ashton. I also gave Ashton 15 blue prints of all the new machinery. The first I gave him was in January and the last in March. Mr. Ashton told me to get blue prints of all new machinery, especially the World's Fair and Niagara Falls machines. He was not my boss and had no right to tell me to get any blue prints. He paid me $30. I gave him the Niagara Falls blue prints a week after the drawings were made.

Clerk McCullough, of Newell's Hotel, was called, and from his register showed that Mr. Hopkins was Hamilton, one of the defendants, who stopped there from February 8 to February 16. A typewriter was taken to his room. Mr. Morris Mead and Mr. Ashton called on "Mr. Hopkins" frequently. They didn't call together.

Clerk Cunningham, of the Monongahela House, also had his register with him. Attention was called to December 22, 1892, to names Chas. E. Clark and brother, of Chicago. It is claimed one of them was W. J. Clark.

Levi Shaffer, a waiter at the Monongahela House, said he served meals in the room occupied by Clark. Mr. Mead and Mr. Ashton were in the room and took meals there, and seemed to have lots of work on hand.

Mr. Martin told of having sent a typewriter to Newell's Hotel, February 8, for Mr. Hopkins. It was used two days.

THE DEFENCE.

The cross-examination of Ashton by the defence failed to elicit much that was new. The witness was perfectly cool, and could not be made to contradict himself. He seemed to be oblivious of the fact that his own position in this matter is even worse than Mead's or Clark's.

The defence attempted to show that Ashton's services to the General Electric Company were in the line of procuring information in regard to the stopper lamp, and to various machines, etc., on which the General Electric Company claimed infringement by the Westinghouse Company.

Mr. Clark testified further that he had reason to suspect that drawings of new machines, etc., had been surreptitiously obtained from the Lynn factory, and conveyed to the Westinghouse Company by Messrs. Morris and Mayer, and that one object in employing Ashton was to verify these suspicions. He was forced to admit that no evidence had been secured of any such scheme, but endeavored to convey the impression that he believed it to be an actual fact.

In response to Mr. Sanderson's questions, Ashton said :

"During the interview at Youngstown, October 15, with Messrs. Clark and Mead, did Clark say that he had evidence that the Westinghouse Company was procuring information from the General Electric Company, and ask you to investigate as to how information was being received ?"

"He did."

"Did you see any Thomson-Houston blue prints in the Westinghouse works ?"

"I did see some."

"Did you tell him that you suspected anyone was sending them from the Thomson-Houston Company, afterward merged into the General Electric Company ?"

"I did tell him that I thought it was a man named Morris who was sending them."

"You stated, did you not, that while Hamilton was at the Newell House the letters offered in evidence were printed on a typewriter purchased there, and that the machine was also being used for copying some documents relating to a South American scheme of Mr. Mead's ?"

"I did so."

"Did you ever report to Clark having seen Mr. Mayer and Mr. Morris in consultation ?"

"Yes."

"Did you not obtain from the Westinghouse office and send to Mr. Clark a blue print of an alleged infringement of a rheostat or power regulator."

"Yes, sir."

"Did you get a blue print of a thirty horse power railway motor ?"

"I did not."

"Did you try ?

"Yes, I tried, but failed to secure it."

It was then shown that Ashton has been for some weeks practically under the control of Messrs. Good, Scott & Hood, of the Westinghouse Company.

Clark admitted having paid money to Mead at various times amounting to about $12,000.

In behalf of Clark, the following gentlemen were called to testify to his good character: John P. Steidley, of New Haven, Conn., Judge of the Common Pleas; Lucius P. Deming, of New Haven, Conn., a lawyer and ex-Judge of the Common Pleas of New Haven County; N. B. Sperry, postmaster of New Haven; Robert O. Gates, sheriff of New Haven County; D. M. Bassett, of Derby, Conn., a hardware manufacturer; John Jamison, general superintendent of the Subway Company of New York, and L. H. McIntyre, of Philadelphia, chief engineer of the People's Traction Company.

A half dozen of his acquaintances testified to the general unreliability of Ashton, and to the fact that he was a close friend of Morris Mead's.

In their argument, attorneys for the defence laid great stress on one of the main points of Clark's defence—that he was only a subordinate, working under the orders of his superiors, Messrs. Coffin, Knight and Rice. Mr Marshall raised the question why these latter gentlemen had not been called to appear.

District Attorney Burleigh responded that an attempt to extradite Messrs. Coffin, Knight and Rice had proved unsuccessful through the opposition of the very attorneys who were now defending Clark. The prosecution also wanted to know—would be very glad to know—why Messrs. Coffin, Knight and Rice had not appeared voluntarily, and had kept out of the reach of the Pennsylvania courts.

THE CHARGE TO THE JURY.

Judge Collier's charge to the jury consumed fifteen minutes, and was in part as follows:

> "If the testimony of Ashton is true, these defendants are guilty as charged—guilty of one of the most dishonest and dishonorable acts in business life, and a most foul conspiracy. Do you believe Ashton? It is my duty to warn you to scan the testimony of an accomplice, and it is not safe to convict alone on the uncorroborated evidence of Ashton. The true course is to direct an acquittal where the evidence of an accomplice is not corroborated in some material point; not all the testimony of an accomplice need be corroborated, but some material point. The question is, has he been so corroborated? This the Commonwealth strongly contends has been done, not only by its witnesses, but by one of the defendants. That is for you to say. If you so find, there is no doubt of the guilt of these defendants.
>
> "Evidence of good character is always in favor of innocence. It does not mean that a man of good character can commit no crime, because we all know men of excellent characters have committed crimes, and when such men do commit crimes it is the more unpardonable."

THE JURY COULD NOT AGREE.

At 9.50 A.M. on Friday the case went to the jury. When no verdict was reached at noon, suspense was manifested; when it had not agreed at 1 P.M., when court reconvened, belief that there would be an acquittal was general; but when, at 5 P.M., court adjourned and no conclusion had been reached, the general opinion was that a mistrial would result, and when at the opening of court no verdict was handed in, it became a certainty that the case must be retried.

On Saturday, after having been out 24 hours, the jury came into court and announced it impossible to agree.

HOW THE JURY STOOD.

When the jury went out and took its first ballot the result was six to six. The second, third, fourth, fifth and sixth ballots resulted the same way. On the seventh, the vote stood seven to five for conviction.

The voting continued until 2 A.M., when the vote was eight to four in favor of conviction.

No more votes were taken till after breakfast, when the final vote was taken, and the result was eight to four for conviction.

District Attorney Burleigh says the case will be retried within the next two or three weeks.

THE POSSIBLE PENALTY.

The act of March 31, 1860, provides that if any two or more persons shall falsely and maliciously conspire and agree to cheat and defraud any person or body corporate of his or their money, goods, chattels or other property, or to do any dishonest, malicious, or unlawful act to the prejudice of another, they shall be guilty of a misdemeanor, and on conviction be sentenced to pay a fine not exceeding $500, and to undergo an imprisonment by separate or solitary confinement at labor or by simple imprisonment not exceeding two years. There are five counts in the indictment, and the penalty provided for may be imposed on each count of the indictment.

Municipal Plants.

Some Suggestions offered by an Advocate of City Ownership.

The following letter, which was sent to a customer by one of the large electrical companies, is published as a contribution to the literature of the much vexed question of municipal ownership of electric light plants:

"The most serious question now before municipalities in this country is, 'Will it pay for us to purchase an electric light plant and do our own city lighting?' While every city in the country (except St. Paul, Minn.,) recognizes the superior advantages of electricity as an illuminating agent, and the statement that 'every electric light is as good as a policeman,' has become an aphorism, yet our cities find that these glowing arc lamps cost money, and that in hard times such as are now upon us taxpayers are apt to grumble at the expenditure and oppose extensions. City officials and taxpayers are apt to believe that a plant operated by the city can be so managed as to effect a large annual saving in the cost of public illumination while at the same time permitting of extensions to remoter parts of the city without unduly increasing the expense.

"If such a plant can be divorced from politics, if it is erected on scientific principles and managed with good business tact, there is no reason why the hopes of the public may not be realized and a great economy secured. In this opinion we differ from the published statements of many of our competitors, whose business interests in existing plants may have something to do with the sharpness of their vision.

"Our reasons for holding this opinion are very simple. The ordinary electric light plant in the ordinary American city is a very different thing from what it ought to be, and the revenue which its proprietor fails to derive from the public he must get out of the municipal lighting.

"To illustrate: An individual or a company decides to locate an electric light plant in a town. There is usually a scarcity of ready funds for the enterprise, so that the plant is installed in a haphazard, get-there-as-you-please kind of a way, trusting to future profits to supply the things lacking for a good job. A single-acting slide valve engine of the commonest type is purchased, from two to six dynamos of the highest possible speed and least possible amount of metal are installed, wire with a cheap grade of insulation is put up in a slipshod way, and the alleged 'plant' is complete. Possibly a transformer is stuck in front of each residence as a current and coal pile consumer, while the arc lamps are full of dust and junebugs in the summer, and loaded up with snow by the fag end of every stray blizzard which wanders around from the Dakota banana belt in the winter. No one knows how much steam is wasted through leaky valves, because the engine is never indicated. No comprehensive system of electrical testing is in use to determine the leakages in this direction. Some customers pay by a meter, which may or may not be right; some pay by contract, and some do not pay at all. It is safe to assume that none pay for what they use. We have tested stations in which only 40 per cent. of the current was paid for, the remaining 60 being dead waste. We have found engines using 12 pounds of coal per horse power, instead of 4 as they should. We have found dynamos so badly built, used or abused, that they could not possibly develop 70 per cent. of efficiency. For these reasons and others many plants do not pay. Therefore the city must be charged an exorbitant price for its street lighting to keep the moribund concern in existence. Where the conditions are as we have indicated, or even where matters are not so bad, a good city plant will pay and render good service, if the errors so commonly made are avoided.

"The usual custom when a city desires to purchase an electric light plant is to have plans and specifications prepared by some local civil or mechanical engineer who may or may not have some knowledge of the latest inventions and improvements in electric science. Bids are called for from the manufacturers of apparatus, and the contract is let either to the man who will do the work the cheapest or to him who has the strongest 'pull' in the Council. The result is that the successful bidder furnishes the cheapest possible plant, and in five years the city has a scrap heap on its hands, worth its weight in old iron and copper.

"The correct way would be to employ in the first instance a draughtsman competent to make a plan of the city and locate the lights, not forgetting to put in the public buildings with the probable number of incandescent lights used in each. Then send blue prints of this plan to all the manufacturers, with a brief statement of the necessities of the work, asking each to submit a bid for the best possible plant according to the system which he think will do the work. Then, and not before, call in the advice of an expert. The professors in those universities which have an electrical engineering course can usually be depended upon for an impartial opinion, and these gentlemen are almost without exception men of the highest scientific attainments. It is also well for the Council to send a commission to visit the factories of any company which may seem disposed to exhibit its methods of construction, and such commission should include at least one competent mechanical engineer.

"In this way any city may be reasonably sure of getting the best in the market. It may not be the cheapest in the first cost, but it will demonstrate its value with time.

"When your plant is erected and running, employ a competent electrical and mechanical engineer to operate it, and pay him a handsome salary. Then allow no interference. The usual custom is to have one autocrat at the engine end of the dynamo room and another at the dynamo end. Each is profoundly ignorant of matters in the other's department. This is all wrong. Men can be had in plenty who have had both technical training and practical experience. Get one of this kind, and, if possible, go about 2,500 miles away from home to find him. He will then have no entangling alliances, political or social, and if his salary depends upon the amount of the annual operating expenses, as it ought to, he will hustle to save money.

"In Europe, nearly all municipalities are far better administered than in this country, and at very much less expense. It has there been found that municipal ownership is the safest plan, and most of the large plants now in operation as well as those now in course of installation are owned by the cities. Great care is used in purchasing in order to get the very best, and the results in every instance have been the most satisfactory. There is no reason why the same may not be true in this country.

"In conclusion, a most important point should be brought to public attention. During the late panic, when scarcely any class of business escaped the most serious losses, the large illuminating companies went on serenely about their business, kept their stocks and bonds far above par and paid their usual handsome dividends. No better proof of the absolute safety of electric lighting as a business, when conducted properly, can be given than this magnificent demonstration."

Miss Bertha Lamme, of Pittsburgh, enjoys the unique distinction of being the first and only woman in the world upon whom the degree of electrical engineer has been conferred.

Rapid Transit Plans.

The Commission Receives a Business-like Proposition.

The following statement, made by Mr. William Steinway, president of the New York Rapid Transit Commission, shows that there is still a reasonable prospect that New York will soon have a rapid transit system underground:

"At the last meeting of the Commission we were approached by a firm of financiers, whose name is well known to everybody and is a guarantee of their entire responsibility, and who informed us that they represented a syndicate of capitalists who were ready to bid for the franchise to construct the underground system as laid down by us, to make the deposit we would require, and to ask no help of any kind from the city. This news was exceedingly gratifying to the Commission, for although we have scores of applications for the franchise, up to this time this is the only application from responsible people which has not been saddled with a proviso that the city should guarantee the bonds and have a first lien on the property.

"The firm did not mention the number or the names of the syndicate they represented, but they said that already three-fifths of the capital required had been secured. As this proportion was based upon our estimate of the cost of the system, and that was $45,000,000, the amount ready to be subscribed for the undertaking is a large one. The promise was not distinctly made to have the system in operation in two years, but it has been estimated by engineers and contractors that the system could be completed within that period. There is no doubt that if the enterprise were once undertaken it would be pushed to the earliest possible completion, as every moment lost would mean money lost."

A COMPROMISE.

The Edison Lamp Patent in New York.

In the suit of the Edison Electric Light Company et al. vs. The Mt. Morris Electric Light Company, which is now before Judge Lacombe for decision, a compromise has been effected, and the Mt. Morris Company will hereafter supply its customers with Edison lamps.

The Packard Lamp Case.

Another Non-Infringing Lamp Will Soon be on the Market.

Judge Ricks in the United States Circuit Court at Cleveland has refused the injunction asked for by the Edison Electric Light Company against the Packard Electric Company, but has granted an injunction against J. W. and W. D. Packard as individuals and as officers of the New York and Ohio Company.

This stops the manufacture of the old Packard lamp, but the factory will be utilized in the manufacture of a non-infringing lamp which will be on the market in about a month.

Proposed Electrical Club in Toledo.

A meeting will be held in Toledo, Ohio, on the 18th inst., for the purpose of forming an electrical club or society for study and research in the electrical field. The committee in charge of the project is composed of C. O. Brigham, J. C. DeLong, J. M. McNamara, William Kline, F. B. Perkins, F. Bissell and J. W. Cherry.

In order to reproduce magnetic fields of identical intensity, Dr. d'Arsonval uses a subsidiary coil in series with the main solenoid, and inserts a mercurial thermometer in it. The eddy currents generated in the mercury by the alternating field cause a rise of temperature in the subsidiary coil, which is a measure of the field strength; with four Leyden jars the temperature rises to 150 degs. C. in a few seconds in Dr. d'Arsonval's apparatus.

World's Fair News.

Fort Wayne Company's Plant.

In addition to the Fort Wayne Company's exhibit in the Electricity Building at the World's Fair, which was illustrated and described in the issue of ELECTRICITY of August 23, this company has equipped an important plant at the Fair, of which a general view is given in our Frontispiece this week.

The plant alluded to is situated in the central aisle in Machinery Hall, and in addition to forming an attractive exhibit serves the purpose of supplying current for a large number of arc lights which illuminate the Fair grounds and several of the buildings. These arc light dynamos are of the "Wood" type, and seventeen machines of this well known system are included in this plant. Fourteen of these are 60-light machines, all but one of which supply current for the lamps on the Midway Plaisance, the Casino Pier and the spar buoys in the channel from Van Buren street to the Fair grounds. The power generators, one 80 and one 60 light machine, supply part of the lighting and power circuits in Electricity Building.

All these machines are driven by Buckeye engines, of which there are five of different types and capacities.

Personal.

Mr. W. J. Davidson, of the Short Electric Railway Company, who went to Bangkok, Siam to construct an electric street railway, has returned to his home, having been absent nearly a year.

The new electric lighting system which is now being experimented with on the New York Central Railroad is the invention of Lieut. I. M. Lewis, U.S.A., whose home is in this city.

Wm. H. McKinlock wishes to announce that he is located in rooms 319–320 Manhattan Building, where any communications can reach him, and where he shall be glad to see his friends.

It Beats the Electrical Business.

At the annual meeting of the Westinghouse Air Brake Company, the annual report of President Westinghouse was submitted, and showed total receipts from all sources of about $5,000,000. The net profits figured a little more than $2,000,000.

Legal Notes.

An attachment for $3,000 has been obtained against the Electrical Development Company in favor of Thomas D. Bowen, on thirty notes dated March 1, 1893, payable six months after date to the order of Eaton & Lewis. The company was incorporated about three years ago with a capital stock of $150,000, and was interested in an electric light plant and street railway at Schenectady, N. Y. Samuel Insull was formerly president, but has been succeeded by J. H. Herrick.

William H. Ricketts has been appointed receiver of the Julien Electric Company, formerly of No. 120 Broadway, on the application of David E. Austin, as receiver of taxes.

The sale of the plant of the National Electric Manufacturing Company at Eau Claire has been postponed till November 1 by order of the Court. Judge Bailey, before whom the proceedings were brought, remarked that if, as stated in documents filed, the property was worth $100,000, he would not feel justified in confirming a sale at less than $50,000.

The plant and other property of the Camden, Ark., Electric Light and Power Company has been disposed of at receiver's sale. The property was bought in by the General Electric Company of Chicago. The price paid was $30,000.

Justice Pratt has handed down an order directing the receiver of the Staten Island Electric Light and Power Company to dispose of the property and wind up the affairs of the corporation. Washburn & Moen, the wire manufacturers, objected to the disposal of any of the property until their claims were satisfied.

Foreclosure suits have been instituted against the Beverly and Edgewater Park (N.J.) Electric Light Company.

Proceedings have recently been commenced in the United States Court at Chicago by the American Bell Telephone Company, against several Chicago firms, for alleged infringement of the Bell patent. The defendants in the several suits are: Willis L. Adams, Western Telephone Construction Company, Electric Appliance Company, D'Unger Electric Telephone Manufacturing Company and the Brown Telephone and Telegraph Company. The Bell Company complains that defendants have furnished telephones at less than established prices, and that they have refused to pay royalties. A decree is asked to recover the profits obtained by the sale of such instruments, and also damages.

Motion has been made for the appointment of a receiver for the Thomson-Houston Electric Company of New York in a judgment-creditors' action brought for the sequestration of the company's franchise and property on the ground of insolvency. A judgment was filed for $123 against the company late in June, and the sheriff has returned the execution unsatisfied. The Durand Land Improvement Company holds a judgment for over $80,000 for rent, from which the company's appeal is now pending in the court of last resort. Should the appeal be unsuccessful, the company will be, it is admitted by its officers, in an insolvent condition. This company was formerly known as the East River Electric Light Company.

Boston Notes.

The town of Rockport, Mass., is to be lighted by electricity, the Gloucester Electric Company having made a contract to erect and operate 125 arc lights. The line will be 18 miles long and will be a very difficult one to build owing to the rocky nature of the soil; one section of the line, five miles in length, will require blasting for nearly every post hole.

It is reported in Boston financial circles that the treasurer's office of the General Electric Co. is to be removed from New York to Boston, it having been decided that this department would be most conveniently located in this city.

The topic engaging most public attention in Boston business circles this week has been the resignation of Mr. H. M. Whitney, president of the West End Railway, and its acceptance by the board of directors, to take effect Saturday. Such an important step has been in contemplation for some time past, Mr. Whitney having sold out largely of his interest in the road and being desirous of taking a more active interest in the management of the Metropolitan Steamship and Dominion Coal Companies, in both of which Mr. Whitney is a prime factor. Since 1889 Mr. Whitney has pushed ahead with the electrical equipment of the West End system, which is the most extensive in the world and is now well nigh completed. It has been a mighty heavy load to carry, but Mr. Whitney has carried the load and surmounted about every obstacle. Whatever criticisms may be made of certain phases of Mr. Whitney's administration, the opinion is almost unanimous that he has accomplished a great work for Boston and its suburbs and earned the right and title to retire from the responsible position he so long held.

One of the unmistakable signs and indications that the electrical business is not long to remain depressed and overshadowed by the clouds of financial stringency is the fact that the American Electrical Works, Providence, whose guests the boys were last Saturday at the 15th annual clambake, has seen fit to purchase a very large group of factory buildings covering several acres, and finding that even this extensive new factory will not quite accommodate all the machinery it will need for filling the increasing number of big orders that are constantly flowing in, has had to build additional stories to some parts of the factory. When complete, the American Electrical Works will have one of the most extensive plants of the kind in this country.

Were it not for the large number of hands that are laid off and doing nothing because of the changes that are pending in the control, management and future operations of the General Electric Company, we should be able to report that the electrical firms in and around Boston are busy, which is a fact, and substantially feeling the effects of the improved condition in trade generally.

The new incandescent lamps, both of which may be regarded as Boston specialties, the "Novak" and "New Beacon," are giving good accounts of themselves wherever they are in use. The Waring Electric Company and the Beacon Vacuum Pump and Electrical Company, which manufacture these lamps, are enjoying all the business they can handle. The Beacon Company having announced their readiness to grant licenses to other companies to make the "New Beacon" under royalty, already several lamp firms have opened correspondence with a view to securing such a license. The indisputable fact of the expiration of the Edison lamp patent in November next is going to be a good thing for lamp makers everywhere as well as for the public generally. It looks as if for the present the General Electric Company had more than enough on its hands to take care of without trying to squelch others through the law courts.

Canadian Notes.

Mr. Martin, Q. C., of Cayuga, was in Brantford last week, trying to float a scheme for the construction of an electric railway from Brantford to Selkirk, via Cayuga.

The Gaynor Electric Fire Alarm Company of Louisville, Kentucky, are considering the extension of their business in Canada, and their representative has paid a visit to a number of the more important points in Ontario during the past week.

The Standard Electric Light Company of Ottawa are putting in a new seven thousand light apparatus in their power-house. A new waterwheel is also being added, which will give an additional five hundred horse-power.

The London West Council have passed a bylaw granting an exclusive franchise to the London Street Railway Company to construct an electric line within its confines. The road is to run along Dundas street from the city, across Kensington Bridge, thence along the Wharncliffe highway north to Oxford street, thence east into the city. When this has gone into working order application is to be made for a bridge across the river, into London south, and then the company intend running a circuit through London township by Petersburg. Construction will probably be commenced immediately, and it is expected the road will be in operation by the latter end of October. Power in the meantime will be obtained from the General Electric Company.

The Chaudiere Electric Light Company and the Ottawa Electric Light Company have formed a business amalgamation, to be followed by actual and legal amalgamation as soon as the latter can be consummated. Mr. Robert Blackburn is president of the new company, Senator Clemow vice president, and Mr. Thomas Ahearn general manager.

Peterboro Town Council has passed a by-law granting a bonus of $5,000 to the Canadian General Electric Company upon their locating there all the industries in Canada controlled by them. The chief addition to the present works will be the lamp factory now in Hamilton.

Work in connection with the Kingston Electric Railway has just been commenced.

The storm of last week did considerable damage to the wires of the telegraph companies in many sections of Canada, direct connection with New York being completely cut off for forty-eight hours.

The Niagara Falls Park and River Railway, in order to add new railway stock and machinery to accommodate its large traffic, is now offering to the public $300,000 of stock at par. Although a new enterprise, being in existence only a few months, the road has been taxed to its utmost capacity in transporting passengers.

General News.

What is Going on in the Electrical World.

Kansas City, Mo.—The Consolidated Electric Light Company has resumed the lighting of the city.

Troy, Ohio.—The Miami Valley Electric Road, connecting Troy and Piqua, has been formally opened.

Memphis.—The Citizens' Street Railway Company has in contemplation several extensions of its lines.

Leavenworth. — The Leavenworth Electric Street Railway Company has been reorganized, and matters will soon be in shape for a resumption of work.

Brooklyn, N. Y.—The Brooklyn City Railroad Company has placed an order with the General Electric Company for 200 additional car equipments.

Denver, Col.—The Tramway having become a U. S. mail line, the motorman on each car carrying the mail is obliged to carry a revolver to protect the sack placed in his charge.

Ellicott City, Md.—The Ellicott City Electric Light and Power Company has decided to increase the power and enlarge the plant. John G. Rogers is the president of the company.

Camden, N. J.—It is understood that the West Jersey Traction Company has secured a controlling interest in the Haddonfield and Camden Turnpike Company, and will at once set men to work on the electric road to Haddonfield.

Savannah, Ga.—The Electric Railway Company has secured control of the Belt Line Railway and will improve the line. The capitalization of the Electric Railway Company will be increased to $600,000, and the bonded debt will be $800,000.

Lancaster, Pa.—The Columbia and Donegal Electric Railway Company has decided to extend the road to Marietta and to commence work as soon as possible. The proposed line will be three miles in length. Mr. F. A. Given is the superintendent.

Niagara Falls, N. Y.—The Canadian Electrical Association during their convention at Toronto this month purpose taking a trip to Niagara Falls to inspect the great tunnel and connecting works. They are expected at the Falls on the 14th inst.

Bridgeport, O.—The opening of the Wheeling, Martin's Ferry, Bridgeport and Bellaire Street Railway Company was the occasion of a public celebration. The road has been completed in five months under charge of Manager J. K. Jolly and Chief Electrician C. B. White.

Troy, N. Y.—A telephone company, managed and controlled, it is authoritatively said, by Lieut. Gov. Sheehan, John H. Gleason, M. A. Tierney, and others very close to Senator Murphy, is about to enter the field as the competitor of the Commercial Telephone Company.

Jersey City.—The Jersey City and Bergen Railroad Company has begun work upon the alteration of the street car route through Bayonne from a mule line to the trolley electric system. The company has promised to have electric cars in operation by December 1.

Warsaw, Ill.—H. C. Riner, of Keokuk, has been granted a franchise to erect poles and wire the city for the transmission of electricity for illuminating, heating and power purposes, with a proviso that work should be commenced within one year and completed within two years.

Toledo, Ohio.—The gentlemen representing the company which proposes to construct an electric line between Detroit and Toledo are working hard getting the right of way, and are holding meetings through the county with farmers, with a view to obtaining the right of way in different townships.

San Francisco. — The San Francisco and San Mateo Electric Railroad Company has secured a contract to carry the United States mail between this city and Ocean View, Colma, Holy Cross and Baden. The agreement is for two years and will commence on October 1, when regular trips will be made.

Salem, Mass.—The new power station of the Lynn and Boston street railroad is rapidly approaching completion. Expert machinists from the Hamilton-Corliss engine company, Dayton, Ohio, are at work setting up the three 500 horsepower engines which will drive the three 300 horse-power generators.

Wilmington, Del.—The incorporators of the Wilmington, Chester and Philadelphia Electric Railway have decided to build a trolley link to join the Chester Railway at Linwood so as to connect all the above points. The railroad will be commenced and completed within one year. The line will pass through Essington, Chester, Thurlow, Ridley Park, Lamokin and Linwood.

Scranton, Pa.—The Scranton Traction Company have secured a fifty years' lease of the track, poles, etc., of the Scranton and Pittston Traction Company's line, sixteen miles in length, and running through Taylorville, Minooka, Duryea, Moosic and Old Forge. The road will be continued to Pittston, and within a short time cars will be running on the whole route from Pittston to Scranton.

Selkirk, Can.—A project of an electric railway from Brantford via Oshweekin (Indian Reserve), Hagersville, Nelles Corners, Balmoral to Selkirk and the lake port south of here, and the dredging out of the bar across the mouth of the creek and making of Selkirk a summer resort, is under consideration by several interested residents. The distance would be about thirty miles over a level country without any engineering difficulties.

Pottstown, Pa. —An electric railway company composed of local capitalists has been organized here to run a line to Ringing Rocks, a well-known resort north of Pottstown, where 250 acres of land have been purchased for a park. The officers of the company are: President, Cyrus Q. Guildin; vice-president, Samuel Fronheiser; secretary, R. E. Shaner; treasurer, A. K. Shaner; directors, Frank S. Brant, George C. Hollenback, Jacob S. Bahr, M. R. Davidheiser, H. M. Boone.

Cincinnati.—On the 4th inst. the brake on an East End electric car refused to work on a steep down grade; the car, loaded with passengers, rushed down the hill with frightful velocity, but fortunately became derailed at a curve, and after plowing up several yards of cobblestone came to a standstill. Some of the passengers were badly bruised in jumping from the car, but no one was killed. On the previous Sunday night a similar accident, from the same cause, occurred on the Avondale line, resulting in fatal or serious injuries to several passengers.

Washington, D. C.—A bill for the incorporation of the Washington Traction Company of the District of Columbia, with a capital of $1,000,000, was introduced in the Senate. The incorporators are R. N. Batchelder, E. W. Rollins, E. O. McNeir, S. W. Curriden, J. R. Baldwin, A. J. Warner, H. S. Cummings, C. P. Williams, N. B. Sweitzer, H. M. Earle and A. G. Wheeler. It will use the underground traction system in use on the Rock Creek Railroad Company's U street line, and outside of the city limits will operate with an overhead trolley.

Interior Conduit Company Claim Infringement.

It is apparent by the vigorous manner in which the Interior Conduit and Insulation Company push their patent litigation that they at least believe they own and control the conduit system of wiring. Their last move in this direction is the suit they have brought against the firm of Carpenter & Tremaine, contractors, who are doing the wiring in the new City Hall at Brockton, Mass., and using the Vulca ducts in the installation. Moreover, it is stated on very good authority that bills of complaint are now being drawn up by the attorneys of the Interior Conduit and Insulation Company against other contractors and owners who are making use of the Vulca tube in other infringing installations.

Shultz Belting.

The following testimonial has been received by the New York agent for the Shultz Belting Company:

A. B. LAURENCE, Esq., New York.

Dear Sir: Enclosed find our check for $8.55 to balance account.

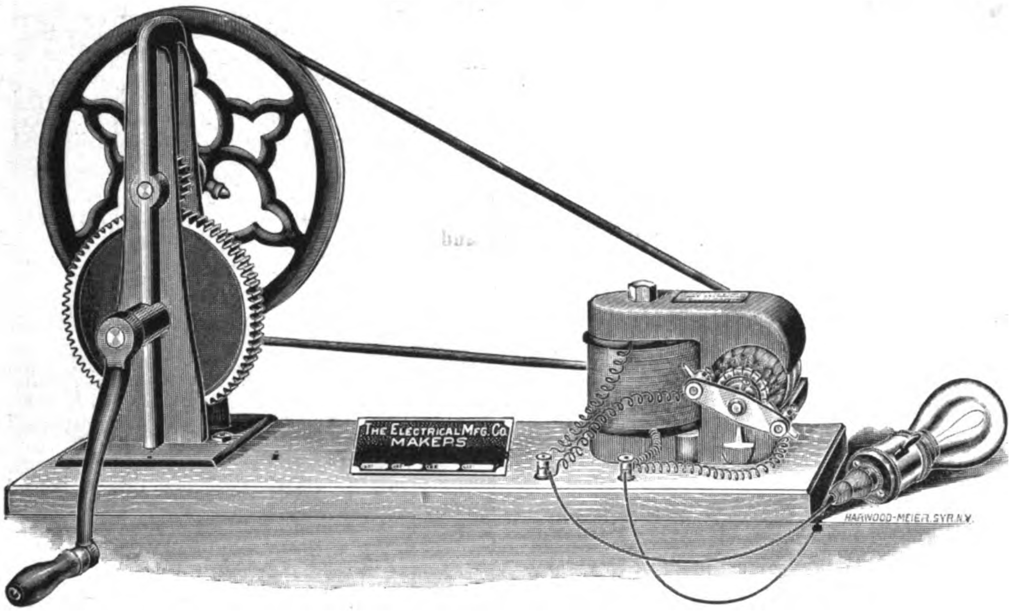
The pulley covering fits perfectly and works like a charm. A belt which we were formerly obliged to run so tight that the bearings were always hot we can now run so loose that it almost drags on the floor.

You are at liberty to use us as reference if you wish.

Yours very truly.
GEO. K. PAGE,
Manager Perry Electric Light Co., Perry, N. Y.

New Model Experimental Dynamo.

The accompanying engraving shows the improved Model Dynamo manufactured by the Elbridge Electrical Manufacturing Company of Elbridge, N. Y. The machine was designed especially for the use of schools and students of electricity, and to them is invaluable since it gives the whole theory of the modern dynamo and follows in construction every detail found in large generators. It is made for actual use, all parts being made of the best material and in the most substantial manner. The armature core is laminated and wound with double covered wire; its shaft is of steel and runs in brass bearings. The commutator has sixteen bars, ample brush contact and will wear for years. All machines are shunt wound, unless otherwise ordered.



THE ELECTRICAL MFG. CO. MAKERS
HARWOOD-MEIER. SYR. N.Y.

The New Model Experimental Dynamo.

The hand power has gears cut from solid metal which run without noise, steel shafts and the pulley turned and balanced.

Each dynamo before leaving the factory is set up and tested to 50 per cent. in excess of the rated voltage as marked on the base.

The machines are furnished wound for from 5 to 25 volts.

The company also manufacture for use in connection with this machine a voltmeter reading from 1 to 25 volts, an ammeter, apparatus for electrolysis, induction coils, magnets—in short, almost any apparatus that would be required by the teacher or student of electricity.

See their advertisement in this issue, and if interested send for circular.

Deservedly Honored.

The high favor in which the well known electrical measuring instruments produced by the Weston Electrical Instrument Co. of Newark, N. J., are held by the most prominent electricians at home and abroad is again illustrated in a very pleasing manner. We refer to the adoption of these instruments at the suggestion of Prof. Ayrton for all tests to be made by the Committee of Judges in the Department of Electricity at the World's Columbian Exposition. The compliment is assuredly deserved and the action of the committee is universally applauded.

INCORPORATIONS.

The Ringing Rocks Electric Railway Company, Pottstown, Pa.—to construct and operate an electric railway in Pottstown, Pa. Capital stock. $100,000. Promoters: Cyrus Q. Guldin, Pottstown, Pa.; Geo. C. Hollenback, Sanatoga, Pa.; Ralph E. Shauler, Pottstown, Pa.

The Susquehanna Electric Light, Heat and Power Company, Spangler, Pa.—to furnish electricity for light, heat and power, etc. Capital stock, $20,000. Promoters: Jas. A. McClain, Bellefonte, Pa.; J. J. Hauk, Carrolltown, Pa.: W. F. Taylor, Altoona, Pa.

The Lititz Electric Light, Heat and Power Company, Lititz, Pa.—to supply light, heat and power by means of electricity to the public in Lititz Borough, Lancaster County. Capital stock, $4,200. Promoters: Jas. E. Brobst, J. Frank Buch, H. S. Kauffman, Lititz, Pa.

The Knoxville Electric Light and Power Company, Knoxville, Ill.—to manufacture and furnish electric light. Capital stock, $20,000. Promoters: Aaron L. Warfel, Chas. F. Foote, Wm. H. Moorehouse.

The C. H. Brown Electric Battery Company. Portland, Ore.—to supply electricity for lighting and heating purposes, and to generate power for manufactories. Capital stock, $100,000. Promoters: Charles H. Brown, Aderville P. Armstrong, Thomas Walker, Louis Pranger, Charles E. Wilber, James Posey, Thomas M. Rogers and Thomas R. Demorest.

The North American Automatic Manufacturing Company, of New York City—to manufacture automatically and electrically operated machines. Capital stock, $15,000. Directors: Thomas F. O'Conner, Daniel P. Regan and Earl G. McQuaide, of New York City.

The Citizens' Electric Light, Heat and Power Company, Lykens, Pa. Capital stock, $10,000. Promoters: F. J. Douden, J. J. Nutt, J. B. Whitney, Lykens; M. R. Keiper, Elizabethville, R. E. Moyer, Millersburg; A. Fortenbaugh, Halifax.

The Electric Letter Box Company, of Meriden, Conn. Caital stock, $8.000. Incorporators: R. L. Baldwin, Benjamin Barnes and John Tederick, all of Meriden.

Empire Electric Company, at Chicago. Capital stock, $15,000. Incorporators: David A. Bennett, Henry G. Hinkle and Gustave Schroeder.

ELECTRICAL PATENT RECORD.

Letters Patent Issued Aug. 15-22, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

503,136. Trolley Wheel. John F. Hall, Lincoln, Neb. Filed April 1, 1893.

503,421. Trolley Wire Finder. Henry C. Jones, Montgomery, Ala. Filed May 31, 1893.

503,562. Electric Trolley Wheel. John W. Clark, Menanda, assignor of one-half to Samuel J. Haight, Albany, N.Y. Filed Feb. 23, 1893.

503,566. Electrical Supply System for Railways. Joseph W. Bates, Minneapolis, Minn. Filed Feb. 8, 1892.

503,570. Electric Railway Trolley Switch. John H. Allison, Elkhart, Ind., assignor of one-half to John G. Rich, Auburn, N. Y., and Daniel G. Reed, Richmond, Ind. Filed March 3, 1893.

503,710. Contact for Conduit Electric Railways. Adolph Worner, Buda-Pesth, Austria-Hungary, assignor to Siemens & Halske, Berlin, Germany. Filed May 18, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

503,349. Incandescent Lamp Socket. Charles T. Lee, Boston, Mass. Filed May 3, 1892.

503,538. Electric Arc Lamp. Louis E. Howard, Plainfield, N. J. Filed Dec. 20, 1892.

503,539. Electric Arc Lamp. Louis E. Howard, Plainfield, N. J. Filed June 9, 1893.

503,602. Electric Search-Light Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 19, 1893.

503,650. Incandescent Electric Lamp. Edward E. Cary, Boston, and William E. Nickerson, Cambridge, Mass. Filed April 3, 1893.

503,669. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass Filed April 7, 1893.

503,670. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 19, 1893.

503,671. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 17, 1893.

503,688. Electric Lighting System. Lucien Vialet-Chabrand, Ciotat, France. Filed April 2, 1892.

503,693. Switch for Electric Lights. Ernest Blasser, Boston, Mass. Filed Aug. 3, 1892.

503,770. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 3, 1893.

503,799. Electric Arc Lamp. Walter W. Millard, Fenton, Mich. Filed April 3, 1893.

503,912. Combined Gas and Electric Light Fixture. James A. O'Neill, Boston, Mass., assignor of one-half to John C. Hollings, same place. Filed Oct. 29, 1892.

DYNAMOS, MOTORS, ETC.

503,183. Alternating Current Electric Motor. Ferdinand A. Wessel, Boston, Mass. Filed April 3, 1888.

503,213. Electrical Reciprocating Motor. Henry S. McKay, Boston, Mass. Filed May 13, 1892.

503,420. Clutch for Electric Motors. William A. Johnston and Arthur W. Browne, Prince's Bay, N. Y., assignors to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed March 3, 1893.

503,445. Method of Winding Coils for Dynamo-Electric Armatures. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed April 19, 1893.

503,449. Method of Winding Coils for Dynamo-Electric Armatures. John B. Blood, Lynn, assignor to the General Electric Company, Boston, Mass. Filed April 19, 1893.

503,458. Regulator for Electric Motors. John C. Davidson, Prince's Bay, N. Y., assignor to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed March 8, 1893.

503,487. Electric Engine. William Lawrence, New York. N. Y., assignor to the Lawrence Electric Company, same place. Filed Aug. 17, 1892.

503,568. Starting Device for Electric Motors. Alton D. Adams, St. Paul, Minn. Filed Oct. 19, 1891.

503,574. Dynamo-Electric Machine or Motor. Charles S. Bradley, Avon. N. Y. Filed April 15, 1893

503,[illegible]61. Self-Exciting Alternate-Current Electric Generator. Philip Diehl, Elizabeth, N. J., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed April 11, 1887.

503,690. Apparatus for Controlling Electric Motors. Schuyler S. Wheeler, New York, N. Y., assignor to the Crocker-Wheeler Electric Company, same place. Filed June 6, 1892.

503,750. Regulating Apparatus for Electric Motors. Charles H. Richardson, Philadelphia, Pa., assignor to the S. S. White Dental Manufacturing Campany, same place. Filed April 27. 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

503,272. Telegraphic Apparatus. Albrecht Heil, Frankisch Crumbach, Germany. Filed Feb. 13, 1893.

503,590. Telegraphy. Stephen D. Field, Yonkers, N. Y. Filed Jan. 16, 1893.

BATTERIES, ETC.

503,182. Battery Jar. Alvah M. Gee, Edgar, Neb. Filed Feb. 18, 1893.

503,415. Electric Dry Cell. Ramon Gabarra, Barcelona, Spain. Filed Jan. 18, 1893.

503,567. Galvanic Battery. Charles H. Brown, Portland, Ore. Filed May 3, 1893.

MEASURING INSTRUMENTS.

503,589. Electric Measuring Apparatus for Alternate Currents. Sydney Evershed, London, England. Filed Dec. 22, 1891.

503,595. Electric Meter. Fred L. Gregory, Niagara Falls, N. Y. Filed May 14, 1892.

503,805. Electric Meter. Anthony Reckenzaun, London, England, assignor to James A. Pentz, Philadelphia, Pa. Filed Nov. 26, 1892.

SWITCHBOARDS AND SWITCHES.

503,115. Test System for Multiple Switchboards. William D. Allison, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 14, 1888.

503,157. Switch for Electric Circuits. William McNeill and James H. Tinder, Winchester, Ky., assignors to the McNeill-Tinder Electric Company, same place. Filed May 31, 1892.

503,180. Electric Switch. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Oct. 29, 1892.

503,279. Controlling Switch for Electrically-Propelled Vehicles. Harry P. Davis, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Co., same place. Filed Jan. 7, 1893.

503,443. Trolley Wire Switch. Elmer A. Sperry, Chicago, Ill., assignor to the Sperry Electric Railway Company, Cleveland, Ohio. Filed April 1, 1892.

ALARM AND SIGNALING APPARATUS.

503,187. Fire-Alarm and Individual Electric Call. John Young, Chicago, Ill., assignor to the Western Electric Company, same place. Filed July 18, 1884.

503,252. Electric Switchboards Signals. Frank A. Pickernell, Newark, N. J., assignor to the American Telephone and Telegraph Company of New York Filed May 15, 1893.

503,505. Railway Signaling. Illius A. Timmis, London, England. Filed Oct. 13, 1892.

503,709. Electric Signal Device. Carl Schwennicke, Berlin, Germany, assignor to Siemens & Halske, same place. Filed March 30, 1893.

503,718. Block Signal Indicating Mechanism. Johann H. Frischen, Berlin, Germany, assignor to Siemens & Halske, same place. Filed May 1, 1893.

MISCELLANEOUS.

503,181. Connector. Herbert L. Webb, New York, N. Y. Filed Feb. 28, 1891.

503,186. Electrical Condenser. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Oct. 5. 1892.

503,193. Cleat. Douglas B. Bronson, Chicago, Ill., assignor of one-half to Thomas B. Wrigley, same place. Filed Feb. 14, 1893.

503,321. Method of and Apparatus for the Transmission of Electrical Energy. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Nov. 21, 1892.

503,384. Cleat for Electric Wires. Jacob Pawolowski, Cincinnati, Ohio. Filed Jan. 7, 1893.

503 427. Binding Post for Electrical Connections. Arnold Kohl, Centralia, Ill. Filed March 24, 1893.

503,451. Apparatus for Electrolysis of Fused Salts. Willard E. Case, Auburn, N. Y. Filed Jan. 17, 1891. Renewed Jan. 21, 1893.

503,519. Conductor Support and Insulator. David T. Bennett, Trenton, N. J. Filed May 15, 1893.

503,549. Insulator. Louis McCarthy, Boston, Mass. Filed Jan. 14, 1893.

503,604. Electric Cable. Milo G. Kellogg, Chicago, Ill. Filed Nov. 15, 1890.

503,621. System of Electrical Distribution. Oliver B. Shallenberger, Rochester, Pa. Filed March 3, 1887.

503,622. System of Electrical Conversion and Distribution. William Stanley, Jr., Great Barrington, Mass., assignor, by mesne assignments, to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed March 28, 1887.

503,727. Electro-Magnetic Safety-Coupling. Ernest Richter and Carl Hoffmann, Berlin, Germany, assignors to Siemens & Halske, same place. Filed Jan. 14, 1893.

503,749. Section-Insulator. Louis McCarthy, Boston, Mass. Filed April 15, 1893.

503,775. Electrical Contact Device. James K. Pritchard, Providence, R. I. Filed March 20, 1893.

503,778. Insulator for Electric Wires. William D. Trimble, Hanesville, Md. Filed April 14, 1893.

503,788. Lightning Arrester. William Le R. Emmet, Chicago, Ill. Filed July 11, 1892.

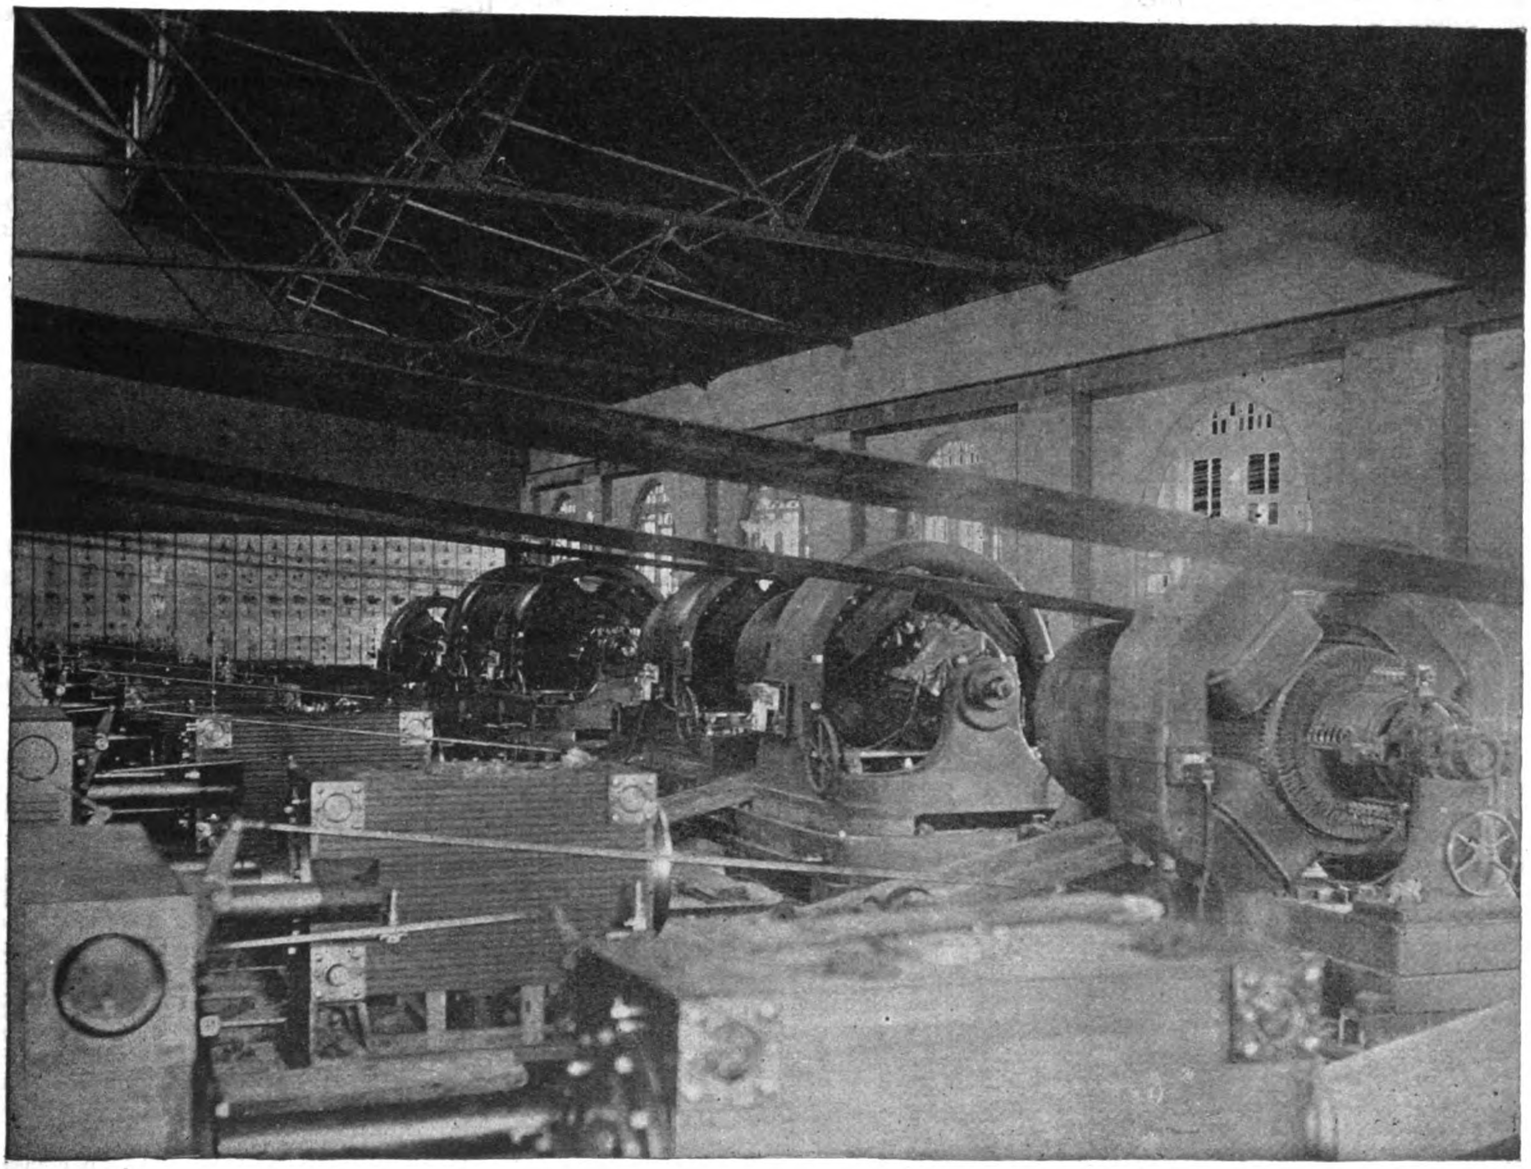
503,811. Electric Belt. Adolph Stephenson and Jonas Backstrom, Stromsburg, Neb. Filed Feb. 23, 1893.

503,867. Electrical Cut-Out. Lewis B. Matson, Elmira, N. Y. Filed Jan. 19, 1893.

503,873. Electrical Conduit for Buildings. James J. Powers and Robert Van Buren, Brooklyn, N. Y. Filed April 27, 1893.

ELECTRICITY.

VOL. V. NEW YORK. SEPTEMBER 20, 1893. CHICAGO. NO. 10



POWER HOUSE, ATLANTIC AVENUE RAILWAY COMPANY, BROOKLYN. (SEE PAGE 114.)

Brooklyn's Latest Electric Railway.

The progress of electricity as a motive power for street railways in Brooklyn has been so rapid during the past year that a horse car in that city will soon be considered a curiosity. Most of the large roads there are already equipped with the trolley, and the latest accession to this field is the Atlantic Avenue Railroad Company, which is just completing its large power station at the corner of Third avenue and Second street.

The building is 268 feet long and 225 feet wide with brick walls and an iron trussed roof. The boiler room occupies 75 feet of the rear end of the building and is separated by a brick partition wall from the engine and dynamo room. It is equipped with six batteries of boilers of the Babcock & Wilcox make, the boilers having a capacity of 250 horse power each. To insure against accident they are provided with three independent feed systems. For ordinary use each engine is belted to a feed pump which operates with it, the feed being regulated by a by-pass which allows some of the water to return through the pump. Two injectors are also installed and there is besides a large pump which is capable of feeding all the boilers.

The piping to the engines is carried entirely underground, and connections are made to the bottom of the engine cylinders.

The engines are of the C. & G. Cooper Company's make and are eight in number. The further engine shown in the Frontispiece has a normal capacity of 375 horse power; the three intermediate ones are rated at 500 horse power, and the other four are 700 horse power each.

To economize space the dynamos are belted back from the engines, which are driven backwards to keep the slack on the upper side of the belts. The engines have a speed of about 75 revolutions per minute, and the distance between centres of pulleys is 45 feet.

The electrical equipment of the road is that of the Westinghouse system, five of the generators being furnished by that company and three by the General Electric Company. The switchboard is made of white marble, and extends nearly across the building. Each dynamo has a separate set of switches and instruments, and each section of the road, of which there are eight, is supplied by separate feeders, any of which may be controlled independently at the switchboard, so that a short circuit or other accident on any section will not interfere with any of the other branches. This station has been in operation for some time, but considerable work remains to be done before its completion.

A Powerful Eel.

It Causes a Total Blockade of an Entire Street Car System.

An eel caused a blockade on the line of the Union Railroad Co. Sunday evening that lasted more than an hour. The company was running 70 cars yesterday, and most of these were loaded with persons returning from a visit to the city's northern suburbs when they were brought to a sudden stop at 6:45 o'clock. An eel three feet long had gotten into the water pipe that supplies the boilers in the power house at West Farms, and the engineer was compelled to stop the engines and blow off the boilers to get at and remove it.—*New York Sun.*

The Ansonia Company's Factory Reopened.

The Ansonia Electric Company has resumed work in every department but one, and with full force. The wire department will not require all the old hands at present, but they will be taken back as needed, and as everything is inventoried it is expected that work will now be carried on continuously.

Convention of the Canadian Electrical Association.

The Third Annual Convention of the Canadian Electrical Association opened in Toronto on Tuesday, the 12th inst. The Exhibition grounds during fair week were chosen as the spot of meeting, and through the courtesy of the authorities ample provision was made for the comfortable accommodation of all concerned. The hall over the public offices was appropriately fitted up for the occasion, and the first day's attendance was fully up to expectations. At 1 o'clock the Executive Committee was called together, and for an hour transacted business of a private character. At 2:30 the meeting was called to order, when the president, J. J. Wright, delivered his annual address. Mr. Wright spoke in part as follows:

Gentlemen of the Electrical Association: It has again become my pleasing duty to meet you in convention assembled, and at this our annual session to congratulate you upon the progress we have made as an association, and on the success which has attended our efforts to advance the interests of the electrical fraternity.

It is not necessary for me to elaborate any platitudes on the wonderful progress being made in the utilization of electricity. This is evident enough to impress even the most thoughtless. The multiplicity of electric cars on our street railroads, the telephones in our houses and the electric motors in our workshops are eloquent realities that impress the fact upon our notice. Apart from the rapid increase of what may be termed the standard uses of electricity, the most notable development appears to be in the increasing use of alternating currents, especially of higher tension than has heretofore been considered practical or advisable.

The use of these currents for light and power will increase with the advent of a practical motor, and it is possible in the near future that current for arc and incandescent lighting and motoric power will be distributed from one source of supply. The chief obstacle to a complete and comprehensive distributing system is the difficulty in running these generators into mains in multiple arc, though even in that line what now is experimental may become in the near future a practical method of operation. We are looking for further developments in this line, as it appears to be at present the most promising field for the enterprising inventor.

I would impress upon the members of this Association, if they would become a power for usefulness, the necessity of taking hold of questions as they arise and dealing with them on new and original lines. It is the duty of an organization of this calibre to lead—not to follow. I am still hoping you will take in hand and endorse with your authority a standard of illuminating power for arc lamps; one that shall be recognized in this country at least as authoritative and final, and shall be referred to as the Canadian Electrical Association standard. If this had been done at the Hamilton Convention when first proposed, we should have led the world. The opportunity still exists, however, as the Chicago Congress failed to take definite action. It still exists, though not to the exclusive extent that it might have done. It will not do to be satisfied to fall in at the tail of the procession and take a back seat as we did, simply because the cross-roads village Podunk has had a four ampere system palmed off on it for 2,000 candle power. If we are to adopt nothing but American ideas we may as well cease to exist and let other people do our thinking for us.

The first day's gathering was a fairly representative one, among the more prominent members present being Fred Nicholls, General Manager Canadian General Electric Company; H. P. Dwight, President G. N.W. Tel. Company; L. B. McFarlane, Manager E. D. Bell Telephone Company; Carl Breithaupt, Berlin; John Langton, Toronto; Prof. Rosebrugh, Toronto; J. L. Armstrong, Toronto; A. A. Wright, Pembroke; John Carroll, Montreal; E. B. Merrill, Toronto; Hugh Neilson, Superintendent Trunk Lines Bell Telephone Company; A. B. Smith, General Superintendent G. N. W. Tel. Company; Geo. Black, Hamilton, etc., etc.

The secretary-treasurer's report was read, showing a most satisfactory condition of affairs and a considerable increase of funds on hand over the previous year, as well as a constantly increasing membership. This was followed by reports of the committees. The report of the Committee on Statistics was read, but as the figures were still incomplete, the press were kindly requested to defer their publication on this account.

It has been ascertained that over $900,000,000 is at present involved in Canada in electric light plants, and the total number of horse power in use 50,000, with something over 4,000 employees.

The Bell Telephone Company has a wire mileage in Canada at the present day of 36,000, with close on to 1,200 employees. There are in the neighborhood of 100,000 incandescent lights in use, 80,000 of which are supplied by the alternating system, and the majority of the remainder by direct current. Total horse power in use for street railways is in the neighborhood of 25,000.

Following the report of the Committee on Statistics, Mr. F. C. Robertson, of Toronto, read a paper on the Causes of Interruption to Telegraph Circuits, which was listened to with considerable interest. Mr. Robertson carefully enumerated the "troubles" common on telegraph circuits, drawing attention to the fact that the Canadian Pacific Telegraph Company was the first in Canada to successfully work a quad. circuit by means of a metallic return during the heavy magnetic storms of last year.

Mr. H. B. Smith thought that Mr. Robertson had omitted probably the most dangerous cause of trouble to which telegraph and telephone companies are now almost daily subjected—a through contact with electric light and trolley wires throughout the country. Mr. Smith strongly denounced the careless methods in vogue among many electric light companies in this respect, which have been the direct cause in many instances of great loss to property in various parts of the country.

"Turbine Water Wheels," a most able paper by A. C. McCallum, C. E., was next read, and the convention adjourned at 5 P. M.

WEDNESDAY.

The Convention was called to order at 10:30, when unfinished business of the previous day was first transacted, and next year's place of meeting fixed upon as Montreal.

The first paper read was by Mr. L. B. McFarlane, of Montreal, giving a history of the telephone in Canada. Mr. McFarlane afterwards stated that the first successful experiment in long distance telephony on the Continent was made by Prof. Bell, between Brantford and Paris, in the year 1875, or one year before that gentleman gave his first exhibition of the practical working of the telephone in the United States, at the Philadelphia Exposition.

Mr. E. B. Merrill, of Toronto, followed with a carefully prepared paper on "Electrical Education," which gave rise to considerable discussion among the members of the Association present as to the value from a commercial standpoint of the theoretical training imparted in the various schools and colleges throughout the country. It was generally conceded that a mixture of both theoretical and practical training was desirable when possible, but the fact that a majority of the important positions in the country were occupied by men whose knowledge has been gained in the field of practice was pointed out as a warning for students that manual work should not be eschewed in their course of training.

The Convention adjourned at 12:30 for lunch and reassembled again at 2 P. M., when the election of officers for the ensuing year was proceeded with. J. J. Wright, of Toronto, was unanimously re-elected president, as were also K. J. Dunstan and John Carroll as first and second vice-president respectively. C. H. Mortimer was elected secretary and treasurer. Papers were read in the afternoon by Mr. John Langton on "Direct Connected Dynamos and Steam Engines," and by Mr. E. Carl Breithaupt on "Electric Street Railways."

Thursday.

The third day of the Convention was devoted to a trip across the lake to Queenston, where a special train was placed at the disposal of the Association by the Niagara Falls Park and River Electric Railway Company from Queenston to Chippewa, and inspection made of the power houses and plant generally.

By invitation the members also visited the Falls at Table Rock and Prospect Park, the works in the tunnel district, the tower, etc., and made a trip around the Falls on the steamer "Maid of the Mist." Luncheon was provided at the Cliff House and dinner on the boat during the return trip.

Long Distance Transmission.

Multiphase Motors.

BY PROF. GEORGE FORBES.*

I read in the morning papers that there has been an organized conspiracy among the American engineers, led by no less a man than our esteemed friend, Dr. Duncan, to "draw" the foreign engineers on the subject of the transmission of power and multiphase motors. Now, in the first place, I presume that has no reference to me. I must say from the relationships which I have had with every one here, I have ceased to look upon myself as a foreign engineer; but even if such an attempt has been made to "draw" the foreign engineers out, I do not see what the object of it was. I do not see that they need any drawing out. They are only too glad to enter into the discussion of the things which are of mutual benefit to everybody.

Your chairman has been good enough to ask me to commence this discussion with some further remarks on the transmission of power and on the use of alternating currents and multiphase motors. I feel that before such an assembly it is a very fitting time that one should say a few words about one of the great works on which I myself have been engaged, and the history of the progress in connection with that work, and the condition of affairs at the present moment in the way of utilizing the Falls of Niagara. A great deal of time and thought has been given to selecting the best system to be adopted for this work, and for a long time the question was open whether the power should be used directly by wheelpits communicating with each separate mill that was going to take the power. It was a resolution of the deepest importance which was arrived at by the president of the Cataract Construction Company when, after having inspected all that was being done in Europe, and knowing all that was being done in America, in the way of transmission of power, he telegraphed to the New York office that it must be a question of starting central stations at the Falls of Niagara. That was the first step that was taken. The question then was whether the power should be transmitted to the workshops requiring power by compressed air, by rope transmission or by electricity, and I may say that for a long time there was a great preponderance of opinion in favor of compressed air. Finally we have all to congratulate ourselves that the resolution was adopted to do the whole of the transmission by means of electricity.

In the year 1890 a number of plans were invited from different engineers and manufacturing firms as to the best means of utilizing this power. These plans were submitted before an international congress consisting of members well known in the engineering and electrical worlds of all countries, who met in London at the beginning of 1891. At that time there was one report which used these words: "It will be somewhat surprising to engineers in general, as it was to myself, to find that the only possible means of transmitting this power to Buffalo, and the best means for using it in the neighborhood of the Falls, is by means of the alternating current." I made that statement in my report after having considered carefully every means which was then available. I am glad to say that I have never had any reason to change my opinion from the year 1890 to the present day. I proposed then that the work should be done by alternating currents generated in two phases; that these should be sent along separate circuits at high voltage; that the transformers should be used for reducing the pressure down and introducing a safe pressure into the workshops; that in the workshops synchronizing alternating motors should be used in some cases, and that in other cases two-phase motors should be employed, and that in the cases where the direct current was necessary alternating motors should be used to drive continuous current dynamo machines. That was in the year 1890, and in the present year, 1893, there is hardly a change to be made upon that system which has been proposed. In the interval of that time, however, we have been only too anxious to hear all that could be said in favor of every different system, and I myself have felt a perfectly open mind in the matter since my having expressed an opinion in 1890; in fact I would not have had the least shame, in view of the rapid progress made during those three years, in changing my views entirely, and to have said that the continuous current was the best for the purpose, but we studied the question very thoroughly. At the time when that international congress was held there was an attempt made among the members of the commission to pass a resolution which was to be transmitted to the Cataract Construction Company, informing them that the alternating current could not be used for the purpose. At the present moment every single member of that commission has changed his views, except perhaps one, and I must say that there is this that electricians can congratulate themselves on in the present state of the art of transmission of power, that whenever a definite problem is brought forward, I notice that if half a dozen able electricians consider the question independently and without personal interests to consult, they are generally very close in accordance in the methods which they advise for adoption. You cannot say that one system is always the best, and undoubtedly each system has times when it ought to be used, but in any one scheme I am bound to say that from what I have seen most engineers will agree if they have got data placed before them.

I mentioned yesterday the chief considerations objectionable in the use of continuous currents for the transmission of power at Niagara Falls. There are many cases where the continuous current is the most desirable to use for transmission of power, and the chief disadvantage is the necessity of putting all your motors in series at the receiving end of the line. But in all these cases that come before the practical engineer the most important thing to consider is the question of cost. At every stage of the working out of the scheme the cost is really the thing that governs the engineer most of all, and it is fortunate when we find that the best harmonizes with the cheapest, as sometimes happens in great engineering works, and as I am glad to say it has happened in the case of this great work of the utilization of Niagara Falls. After the congress closed its labors, and when electricity was decided upon for the purpose, projects were asked for from all the greatest firms in the world. They were asked to submit plans for dealing with this problem. Some were continuous currents and some were alternating currents. The greatest difficulty was experienced in nearly every case by those who were proposing continuous currents to meet the requirements in any way whatever, and in every case the cause was largely in excess of the cost with the alternating currents. One of the things which we have decided upon is that we are to use the same system for the distant transmission as we are to use for the near-by transmission. Nearly every person, when he has begun to tackle this problem, has thought that it was desirable to use a lower voltage for the near-by transmission. One or two thousand volts seemed to be able when you were only transmitting a distance of a mile or two, whereas 10,000 or 20,000 volts was considered nearer right for the distant transmission, but the advantages which we gain by using the higher pressure to a great distance are also gained in using the near-by distribution. Moreover, in all these cases it is almost impossible to grasp the full conditions of the problem until you come down to drawing out the details. Suppose you do start with 1,000 volts for a distribution, say of the first 50,000 H. P. in the neighborhood of the Falls, you will find that the mass of conductors that you have to deal with is something simply impossible. The most convincing argument that I was able to adduce on this point was by drawing a full scale section of a subway carrying the conductors which would be necessary at 50,000 H. P., and it filled a large subway through which a man could walk. It filled the subway up with conduction in such a way as to show, without any further demonstration, that it was impracticable. Moreover, the simplicity of having the whole of the system all in one voltage is something which cannot be overestimated, and this is the way in which we propose to work.

I am glad to feel that the universal opinion is in favor of the adoption of alternating currents. I can only quote one man of any eminence who seriously and persistently considers that it is the greatest mistake to use the alternating current for such a purpose. I will not mention that gentleman's name, and it is a very well known name, one that bears the greatest influence, so great influence that I and those with whom I have been associated have considered with the utmost care every single point in the matter before rejecting the advice that has been given us. The opinion was stated in a general way, but the concrete way in which it was stated by this authority was that on the top of our vertical shafts which come from the turbines we should have a building four stories high for each turbine. Each floor should be insulated completely from the rest of the building. At each floor there should be a large toothed wheel driving five other toothed wheels, on each one of which should be a dynamo of vertical shape. We should have twenty dynamos, each of 1,000 volts, all continuous current dynamos, all connected in series. That plan we have considered most carefully, owing to the source from which it came, and we have rejected it. We are now going ahead with the alternating current, and at every point the question of cost has been considered, and the results which we have arrived at I believe are the best, and I may also say that they are certainly the most economical.

In the year 1890, at the time that I proposed the adoption of synchronizing alternators in some cases and Tesla motors in other cases, there were comparatively few who had much experience of either one or other of these alternating motors. The Tesla motors I had fortunately been able to see at the Pittsburg works of the Westinghouse Company, and they had been placed at my disposal for experiments, and I put a high value on the outcome of these motors, what they would be developed into. I regret to say that during the intervening years there was very little done in the way of developing these Tesla motors at Pittsburg, but in the meantime the question was being taken up in other countries, and in Europe at the time of the Frankfort Exhibition there was a great deal of multiphase work shown in action. This directed the attention of the world to it, and I am glad to say now that in America also the multiphase motors have made more progress. Professor Silvanus Thompson yesterday said that he thought multiphase motors would disappear from general distribution, and that the single phase motors with a multiphase means of starting the motor might be the more universally adopted. That is one of the possibilities of the future. There are several possibilities of the future that we must consider in any very great scheme like that which I am speaking of at the present moment, but in the meantime we must deal with the possibilities of the present. I consider that the multiphase motors at the present moment are not only a possibility, but are a valuable adjunct to the other uses for which the alternating current can be used. Now, a great part of the work in any large system of distribution like that is the continuous working, day and night, or from early morning till late night. A mill is started in the morning and never needs to be shut off during the day, and there are other mills of a character most likely to be attracted to such a situation that run day and night from week's end to week's end. The largest consumers of power which we have at present are the pulp mills for making wood pulp for paper, consuming thousands of horse power, and next to these come the electric deposition works, where power is required from week's end to week's end continuously running. In these cases, if it is simply power you require, a synchronous motor is admirably adapted and thoroughly satisfactory, but in all ordinary workshop practice where we wish to be stopping, starting and reversing our machinery, the most convenient alternating motor, which is a thing not of the future but ready for practical use at the present moment, is the multiphase motor. It is possible to do without the multiphase motor perfectly well, but it is a valuable adjunct at the present moment.

---

*Address before the International Electrical Congress at Chicago.

I will speak of a few other of the possibilities which are immediately before us and within our sight at the present moment, and which there can be little doubt will be available to us in the course of the next few years, but which it would be unwise entirely to depend upon at the present moment. Among these it will be said that I am very careful, perhaps, if I include those commutating machines which have been given the name of rotating transformer, a misleading term, but machines which commutate the alternating current into the continuous current by the rotation of the armature, and this machine was first largely shown to the world at Frankfort in 1891, and chiefly by the firm of Schnecker & Company, and has been largely introduced in America for experimental purposes, at any rate, and to show how thoroughly convenient they are, and there are several specimens of them at the World's Fair. These machines involve rotations of a full sized armature with all the losses involved in the armature of a dynamo machine, and consequently they add to the general losses of the system a loss of some, let us say 10 or 15, per cent. This loss is undesirable. Remember that the sole function of these machines is to commutate the current, and it does seem to me as if the world is speedily advancing in the applications of electricity to be able to devise a commutating machine which shall simply do the act of commutating a current without this great loss of power. A great many attempts have been made in this direction. It is a very desirable aim, in order that we may have machines at a distance from our generating station to work our street railways, which at present are worked by continuous current. If we can carry our high tension alternating current to a distance, to Buffalo, to Rochester, to Utica, Syracuse, Albany, to transform it down to a low pressure, and then commutate it by a simple commutator that is not absorbing power to an appreciable extent, we have a valuable adjunct to our machinery. This is one of the possibilities which is almost certain to arrive in the course of the next few years, and which we must look forward to and not leave out of account.

Mr. Pollak has shown us an extremely valuable and simple way of doing this. As to the successful operation of it in practice many of us have still to learn a great deal, and I am sure that each one of us who is interested in the transmission of power to a distance will take advantage of the offer which has been made to us to inspect his machinery at the World's Fair. Other attempts have been made in the same direction by Hutin and LeBlanc in Paris, and by various other inventors, but I may say that a commutator of a simple kind, not losing over 15 per cent., is a thing which is going to come, and we must look forward to it, although we cannot depend upon the possibilities of the future in the organization of our schemes of the present.

Other things are likewise coming. You have heard of the numerous attempts that have been made to devise single-phase alternating current motors which can be put upon our lighting circuits. These have hitherto been not an entire success so far as they have been actually put upon the lighting circuits. We have seen, however, lately in Switzerland the successful construction of such a motor, which can be put even on such circuits as are ordinarily used for lighting purposes, and this even when the frequency of alternations amounts to 133 periods per second, as is very generally used in this country. Such motors have been produced which work efficiently on those circuits, but there are a large number of motors which, although not quite successful on this high frequency, at some lower frequencies are very efficient and satisfactory. I need not mention the names of all the inventors who have been at work in this direction, for they are countless, and I have seen myself with my own eyes, and worked with my own hands, machines of this class of a great number of different types, all capable of doing good work on a rather lower frequency than what has been used with the lighting circuits in this country.

By-the-by, there is also a type of machine which I proposed for adoption as a possibility in the future with alternating currents in the year 1883, and that is the direct current motor with a laminated field; and that also has a certain amount of possibility in the future, at any rate, with lower frequency than what we have been using. There are some difficulties in its use, but such men as Eickemeyer, Prof. Anthony, N. Tesla and various other gentlemen have been engaged upon work in this direction and it has promise for the future.

Now, another of those things which are promising for the future is the question of arc lighting. At the present moment we could use alternate currents for arc lighting. It is being used for arc lighting in Europe; it is being very largely used in some places for arc lighting. At the present moment in this country it has not been so very largely used for the arc lighting, and most of us are of the opinion that the continuous current arc lamp is a more successful thing than the alternating current arc lamp. In the first stations which have to be supplied from Niagara Falls for the purposes either of traction or of arc lighting, there are existing companies at present doing that work. They have got steam engines driving their dynamos, generating currents for these street railways and for these arc lamps. What they want us to do first is to throw out the steam engines, put in motors to drive these dynamos which they have there, not to throw away their whole plant; therefore these at present come under the consideration of the power stations which have to be supplied. But we shall have to deal with arc lighting systems, and if we can get the direct current easily and satisfactorily from the alternating current, it is a very desirable thing to aim at. This, gentlemen, is one of the possibilities of the future.

Mr. Ferrenti has been at work during the last year in developing a combination of a transformer and a simple commutator which shall convert the alternating current into the continuous current whose value is constant, a current of ten amperes or 15 amperes or whatever we may fix upon, and this commutator of his is not one of those commutating engines which we have seen here, but is simply a commutator which is not absorbing power to a large extent in an armature like the other machines. It is a simple commutator and it is working well, and I have the greatest hopes that that may be developed in the near future.

While telling you what we are doing at Niagara Falls, I have only felt that it was right that I should put before you these possibilities of the future, because it is only right that we should consider most carefully what developments are likely to take place in the next few years, and we ought to provide that the machinery which we put down shall never be obsolete. In the meantime, for reasons which I mentioned to you yesterday, we saw a decided preference among the different systems of polyphase transmission and transformers in favor of a system in which the lines are not interconnected. That system when most simply produced is the two-phase system with two independent circuits, one for each phase. We are going to have dynamos made in two phases, not only because we want to avail ourselves of all developments in this line of working that manufacturers can offer us, but also because we get our single-phase circuits cheaper than if we built the machine with one phase instead of two phases. If we use only single-phase motors then we get a larger output from the same machine by building it of two phases than building with one phase. This was appreciated so early as 1879 by a man whose name we all honor so much in connection with the development of electric work, M. Gramme. M. Gramme's first alternating current dynamos were in two phases, eight poles and two phases with a revolving field and a fixed armature.

As to the motors which we shall be using, we shall be using synchronizing motors of single phase, polyphase, and sometimes, no doubt, converting into continuous current and using continuous current for street railways.

The paper of Mr. Pollak which has been referred to involves what I consider the most important point for electrical engineers to attend to that can be thought of at the present moment, the commutating of the alternating current to give us a continuous current. Every advocate of the continuous current that there ever has been, and there have been bigoted advocates, would have been convinced in favor of the alternating current dynamo, alternating current and transmission, if you could have told him that you would put a commutator at the far end instead of at the place where you generated your power. That is the proper place to put a generator if you are going to put one anywhere at all.

There was a good many special features in connection with the Niagara project which rendered special features in the design of dynamo desirable, and which naturally will differentiate the dynamo which is to be used there from those which have been in more ordinary practice, but I venture to say that there will be no serious departure in the dynamos which are put down from the ordinary lines which we have found to be perfectly satisfactory in the past. One of the features is that we have a vertical shaft instead of a horizontal shaft. As you are all aware, the water of the Niagara River is taken off one mile above the Falls by a large canal which has been built. It is then taken by tunnels into the wheelpits and sent down on pen stocks to a depth of 140 feet to the turbines below. These turbines have been constructed by the I. P. Morris Company in Philadelphia, and will be delivered very shortly. The water, after passing through the turbines, is carried down through the great tunnel which has been built and which is an engineering work to be proud of. On the top of the turbines they have a vertical shaft coming to the surface of the ground, and that shaft rotating at 250 revolutions a minute causes the large dynamo to revolve directly on the same shaft without any gearing whatever at the same speed.

It has been proposed in many cases to generate the current at low voltage and use a step-up transformer to create a higher voltage. There are two objections to this. The first is that we have the cost of the transformer. The second is that we have the extra losses in the transformer. If it is possible to create the whole voltage that we require in the dynamo instead of in a transformer, we save the cost of a transformer, which is approximately, roughly speaking, about the cost of the dynamo, and we are saving some three per cent. of efficiency. Now, three per cent. of efficiency—I do not know if every man realizes that until he begins to count out what it is. It means 150 H. P. in each of our units. Our units are 5,000 H. P. Three per cent. of efficiency saved would be 150 H. P. That means so much more earning capacity to our plant. That means so much more rental to be taken in. Suppose you put that at $20 per annum, and 150 H. P., that is, $3,000 per annum is saved by saving that little three per cent. Three thousand dollars per annum capitalized at five per cent. would be $60,000. By saving that three per cent. you save more than the whole plant and the station connected with that work, the dynamo and the whole thing. When we reduce these things down to figures we see what value a high efficiency is to us. Now, I maintain that by following the example set by Gramme, of having the armature fixed, it may be a little extra expense, but nothing like the expense of putting in an extra transformer. You can build that dynamo to the same voltage that you are going to use with a transformer. The fixed armature becomes a thing as easy to handle and as safe to handle as the transformer itself, and you can introduce your very high pressure into that armature with the same safety that you can introduce it into the transformer.

Now, I will not say more about the general arrangement. I think I have said enough for the present, and I felt that it was only right to say this much before so distinguished a congress at this particular stage of the work. I will say one or two words, if the chairman will allow me, on the question of the means of transmission.

It has been an anxious consideration as to whether the transmission ought to take place by overhead conductors or by means of a subway; also the question of laying underground cable in a conduit has been considered. I distinguish, gentlemen, between a subway and a conduit thus: I consider that a conduit is a place for putting cables in. I consider that a subway is a place for putting cables in where a man can walk along and inspect them. Obviously the most complete and satisfactory method would be to put a subway wherever you want to carry these high tension mains, and the cheapest way is obviously to put a pole line all the distance, and the intermediate way is, as often happens when we try to strike a mean course, disastrous. One of the greatest troubles which is likely to come to this work unless it is watched against with the greatest care, is the trouble arising from the capacity of the line. It was said of the high tension transmission at 10,000 volts between Deptford and London, which was for a long time an experiment, that there were two things to consider in connection with the cables: first their capacity, and secondly their incapacity. Their latter defect has, I am glad to say, according to the latest advices, disappeared entirely, from knowledge acquired as to how to deal with the first defect. Now that the capacity of these cables is handled in a proper manner, in a scientific way, there is no trouble. But capacity is always apt to lead to trouble and ought to be avoided in this case in the cables, and for that reason it is undesirable to have insulated cables acting in this manner; consequently the the work will be done either by overhead conductors, bare wires, or by bare wires carried in a subway. Naturally the cost of a subway to Buffalo is a very serious thing. The first place which we have to supply with power is the Pittsburg Reduction Company in the manufacture of their aluminium, which is at a distance of 2,500 feet from the power house, and we have also to proceed almost immediately to Buffalo. Later on we have to meet the agreements which have been made to supply places situated along the Erie Canal; and since the State of New York has taken up experiments on the possibility of having their towage on the Erie Canal conducted by means of electricity, we have to consider the question of transmitting electricity over the whole of that distance. I may express as a purely personal opinion that the action of the State of New York in this direction is an action of the very highest importance; that it is likely to revolutionize traffic in the State of New York; that the volume of transportation over the Erie Canal will be such as to benefit manufacturers in all parts of the State, and more especially those in the neighborhood of Buffalo and the Falls. This work takes us ultimately to a distance of 350 miles. This involves high electric pressures and it involves the consideration of the expense of laying our line.

I have lately had occasion to deal with a similar problem in India. The Indian Government has lately been irrigating the eastern side of the Nilgharry (?) Hills by means of the rivers on the western side of these Hills, and driving a tunnel through the mountains to carry water to irrigate land. They found that when the water was carried through the tunnel at an elevation of 1,200 feet, within a mile and a half before they wanted to begin to use that water for irrigating purposes, they had sufficient water to develop 50,000 H. P. They have been considering the question of generating electricity, and I have had to look into the electrical question. In that case the greatest development of electrical power and lighting would be at the town of Madras, which is 350 miles from this place, but still, according to the best information that we are able to collect on what has been done at high voltage, it seems almost certain that this power can be carried that distance and delivered at Madras as one of the cheapest forms of power in the world, because all the hydraulic works are already created and their sluice gates and everything prepared, and they are simply putting in the transmission plant.

The transmission from Niagara Falls to Albany is almost identical with this. The distance is the same, and when we come to supply this canal we shall have to consider the question whether overhead poles are possible. In the meantime it will be desirable to have some experiments made upon overhead construction, but in this climate there are very great difficulties. The two most serious difficulties that have to be contended with in connection with transmission for an overhead line are, first, those due to lightning, and second, those due to sleet. The sleet trouble is a very serious one, especially in the northern climate. Broadly speaking, the conclusion which it seems we must arrive at is that a transmission by overhead conductors must in the nature of things in that climate be liable to occasional interruptions, and that the electrical subway is almost certain to be carried out without interruptions, giving a continuous service. This makes one naturally favor the subway system. But experiments will be carried out with the pole system undoubtedly, and I have to conclude by making one statement which I think ought to be a matter of congratulation to all of us who are interested in seeing such a scheme successful, and that is that a subway, at any rate part of the way, has been begun. Last Friday the first sod was turned for a subway which is going to carry the conductors from the power station at least so far as the Pittsburg Reduction Works, which is half a mile distant from the power house.

New Method of Producing Steel.

A new method of producing steel has been suggested to M. Jules Garnier by M. Moissan's diamond making experiments. He claims that it is successful. The steel is instantaneously made by placing a bar of iron and a stick of charcoal together in a parallel direction in an electrical fire-brick furnace of a temperature of 1,000 degrees and subjecting them to a strong current. M. Jules Garnier expects that his discovery will revolutionize the steel industry.

On the Swinburne-Thompson Unit of Light.

BY SILVANUS P. THOMPSON, D.SC., F.R.S.*

In the spring of 1892 it was independently proposed by Mr. James Swinburne and by the author of this note to adopt as a unit of light of standard quality the light emitted from a unit of area of the positive or crater surface of the electric arc formed between electrodes of pure carbon.

The advantages of this source of standard of illumination over all flame standards hitherto proposed are so obvious as scarce to need mention.

The advantages over the platinum or Violle unit are also considerable. The carbon arc is much more easily managed, and if a pure carbon is employed, it is much more reliable as a standard than the mass of molten platinum.

The light of the electric arc is emitted, as is well known, chiefly from the end of the positive carbon, very little proceeding from the flame itself, and not much from the negative tip. The positive carbon is in fact heated intensely hot over a patch from which the column of conducting vapor or flame (called by Davy the "arc") is projected across to the tip of the negative carbon. This luminous patch becomes hollowed out into a crater, white hot all over its surface except at the edges, which are duller and redder, and which volatilize much less, but consume slowly by oxidation when the arc is produced in air. Except at these edge parts the light of the crater surface is of uniform lightness at every part if the carbon be pure. The reason of this circumstance is, as pointed out years ago by the writer, that carbon has a fixed temperature of volatilization. The arc cannot be formed at all unless this temperature is reached at least at some portion of the surface; and the temperature cannot be exceeded at any point, simply because the volatilization of the carbon keeps it down. The temperature of the crater surface, that is to say, the temperature of the volatilization of carbon, is as definite (if the material is pure and the external pressure constant) as is the temperature of the melting point of ice, or as that of the boiling point of water. It appears to be about 3,500 C. All arcs made with a pure carbon emit from the crater (save as regards the marginal parts) a light of equal whiteness, irrespective of the strength of current, or of the voltage, or of the length of the arc. Any variations that are noticed in the apparent colors of arc lamps arise either from the semi-incandescent parts around the edge of the crater, or from the tip of the negative carbon, or from the flame itself. If an arc has been burning for some time with a certain current—say six amperes—its crater will have assumed a certain shape or size. If we now increase the current to twelve amperes, the incandescent surface of the positive carbon will be at once increased in proportion, save for a slight discrepancy arising from the marginal effect of the duller parts, and the enlarged crater will settle down to a new shape. (These remarks relate to the steady arc; the phenomenon of the hissing arc being still very obscure.) If then by proper shielding there can be cut off all the stray light of uncertain quality emitted by the red hot margin of the crater, that emitted by the negative tip and by the flame, so that only the true crater surface is visible, its whiteness, as so viewed through a hole in a suitable diaphragm will always be of the same unvarying quality. This was the discovery of Captain Abney, F.R.S., in 1878; and it forms the basis of all the splendid work done by him in conjunction with Major-General Ferting, F.R.S., on the photometry of color.

Increasing the current merely increases the size of the crater, but does not alter its intrinsic brilliancy or its color. Increasing the voltage of the arc has no effect on the intrinsic brilliancy or color of the true crater surface. Increasing the length of the arc has no effect on the intrinsic brilliancy or color of the true crater. The amount of light emitted from a square millimeter of crater surface is a fixed quantity, no matter how the current, or the voltage, or the length, may be varied; and not only is the total amount of light emitted from a square millimeter constant, but its composition is constant. That is to say, the proportion relatively of red waves to blue waves is the same always, independent of current, voltage or length of arc.

It was in consequence of the recognition of these physical properties of the true crater surface that the writer and Mr. Swinburne each made the proposition for the establishment of a new unit to supersede the Violle standard.

Since that suggestion was placed before the scientific world, some work has been done toward its realization in France. M. Blondel has described under the term *arc nomal* an apparatus closely resembling that used by Abney in his photometric researches, consisting of an electric arc furnished with a metallic diaphragm pierced with an aperture of known dimensions, but with the addition of a water-cooling arrangement. More recently, M. Violle has taken up the subject of the electric arc, and has redetermined the temperature of the crater. He adopts and confirms the author's view, that this temperature is determined by the volatilization of carbon. The author has also recently investigated the possible errors introduced by the thickness of the diaphragm and by its obliquity in its position; he has found these sources of error to be by no means negligible. He has also made some experiments on the purity of carbons, and finds that natural graphites always give a less light intrinsically than the artificially prepared hard carbons. Trotter in his original investigation of the distribution of light as emitted from the arc lamp, announced the different emissivity of the soft carbons used for cores. He also investigated the amount of light emitted (normally) from a square centimeter of hard carbon, and finds it to be something less than 70 candles. Doubtless the imperfections of the photometric methods until recent years were such that the production of an exact standard of white light was of less importance than is now the case, since photometry has become the art of precision. Professor Ayrton, adopting the periodic principle of photometry lately described by the author, and using a photometric screen of the Lummer-Brodhun pattern, finds no difficulty in measuring light with a precision of one part in 500. Now that such accuracy of measurement is possible, there is the more urgency for adopting a standard which is not only of entire trustworthiness, but is also easily reproduced.

A Useful Directory.

The "Directory of Street Railway Exhibits at the World's Fair" is the title of a very useful guide-book published by the *Street Railway Gazette* of Chicago. It contains information which will enable the visitor at the Fair interested in any branch of railway work to readily find every exhibit relating to the same, and the subjects included cover every branch of railway work both as to machinery and rolling stock. The subjects are classified under general heads, each of which directs the visitor to every exhibit pertaining to the heading.

Announcement is also made in this pamphlet of the addition of Mr. Clarence E. Stump and Mr. J. W. Dickerson to the staff of the *Street Railway Gazette*, the former in the capacity of business manager and the latter as a member of the editorial staff.

Both of these gentlemen are too well known in the field of electrical journalism to need introduction, and the *Gazette* is to be congratulated on the acquisition of two tried and successful members in this field.

* Paper read at the International Electrical Congress, Chicago.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 75, 120 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Empiricism. Our usually accurate contemporary, the *Electrical World*, points out in an editorial discourse the danger of dogmatisms which are not uncommon in the literature of electrical science.

Taking as its text the remarks of Prof. Crocker at the International Congress on this subject, it says:

> "For many years the rule was laid down that the difference of potential between adjacent bars of commutators should not exceed 9 volts, yet Prof. Crocker describes two machines which worked successfully, one with a difference of 100 volts and the other with 150 volts. While the successful working of these machines was partly due to the use of carbon brushes . . . nevertheless the arbitrary dictum in regard to the limiting potential between the bars of commutators has been definitely disposed of and the way thus opened for a new advance."

While we heartily concur in the conclusions drawn by our contemporary, and in the justice of its comments on this subject, the figures actually given by Prof. Crocker are remarkably at variance with those imputed to him by the *Electrical World*, which are not nearly so striking an illustration of the case in point. The figure formerly laid down in regard to the maximum average difference of potential between commutator segments was 19 volts instead of 9.

Then of the two machines described, one having a 32 segment commutator generated a current of 5,500 volts, which would make the average difference approximately 350 volts, and the other, which generated 11,000 volts, had 108 segments, or a difference of over 200 volts.

By substituting the figures 200 and 350 for those quoted above, the uselessness and fallacy of the old arbitrary limit of 19 volts is made still more apparent.

……o……

Mercurial Air Pumps. An entirely novel form of mercurial air pump is described in a paper by Mr. Schulze-Berge printed elsewhere, and the subject is one of great interest to electricians on account of the prominent part this machine plays in the manufacture of incandescent lamps.

In the older forms of pumps, which were made of glass, trouble has been experienced frequently by the breakage of the glass due to concussions, and another trouble lies in keeping the mercury clean. Besides avoiding these difficulties, Mr. Schulze-Berge's pump is capable of producing rapidly an unusually high degree of vacuum, so high, according to the author, as not to be measured by the McLeod gauge.

To avoid the risk of breakage, these pumps when manufactured in large sizes suitable for lamp factories are made with cold-drawn steel tubing which, contrary to the accepted theory, Mr. Schulze-Berge finds will stand any degree of vacuum he is able to produce. The joints in these tubes, instead of being connected by electric welding, are soldered on the outside after inserting a platinum washer between the ends of the tubes to prevent the mercury from affecting the solder.

A pump of this design is now being tested for an incandescent lamp manufactory which from the performance of the smaller models promises to be a considerable improvement over older styles of vacuum pumps both in the degree of vacuum produced and speed with which the work is accomplished.

……o……

Electric Arc Lamps. The number of papers in regard to arc lamps read at the Electrical Congress would appear to indicate that considerable study is being given to this now almost universal means of outdoor illumination, yet it is probably a fact that notwithstanding the extent of the use of arc lamps they have received less attention from electrical engineers than has any other important piece of electrical apparatus.

This condition arose at first, perhaps, from the very rapid introduction of arc lighting and the necessity of supplying some kind of a lamp for commercial purposes. Customers at first had very little idea of what constituted a good lamp, and so long as it continued to run without too much flickering and without going out too often the customer was satisfied. This led to the manufacture of a class of very cheap lamps, and in a good many cases everything possible was sacrificed to produce lamps with few parts and of low shop cost, without much regard to efficiency or reliability. The result of this was plainly evident in the numbers of lamps which could be seen out almost any night.

In some cases the shop cost of lamps was reduced to about five dollars, but very few of these are to be found to-day. The tendency is now in the direction of improving the mechanism which even in the best of lamps is a delicate and somewhat uncertain point, and complaints about lamps going out are still familiar to central station men, although not nearly so common as formerly.

A good deal of the work in this line appears to have been done by people who had but little idea of the requirements of a good arc lamp, and this is particularly noticeable in the patent records. The number of lamps and devices upon which patents have been taken out is well up in the thousands, but as very few of these have found any practical application it is to be inferred that most of them are of but little value.

In fact, the different kinds of lamps in use to-day are limited to a very small number, and the most of these are turned out by half a dozen companies.

……o……

A RECENT issue of the Alton, Ill., *Sentinel* contains a somewhat lurid report of a mass-meeting in that town, held, pursuant to a call from the President of the Board of Trade, to consider what inducements can be offered to the Chicago-St. Louis Electric Road to secure the location of the company's shops at Alton. Mr. Fisher, for the road, explained how, for proper considerations, several deflections had been made in the proposed route, which was first announced as an air line. We gather that if sufficient "inducements" are offered, the road can be built as crooked as a Virginia worm fence without interfering seriously with the workings of Dr. Adams's "patented devices."

Citizen McPike inquired: "Has not Mr. Thos. A. Edison said that it is perfectly practical for you to operate your line at the intended speed of 100 or even 150 miles per hour ?"

Dr. Adams replied: "He has, I believe, made that statement, and we can certainly do it."

If Dr. Adams has a conscientious desire to inform the public what is thought of his plans by scientific men, he should distribute in pamphlet form the discussion at the meeting of the American Institute of Electrical Engineers which he addressed a year and a half ago ; to which might be added, as an appendix, the opinions published in these columns in regard to it.

······o······

The idea that Mr. R. T. McDonald has withdrawn the Fort Wayne Company from the Trust out of sympathy for Mr. Coffin is the conception of no ordinary brain. Those who are putting it into print should read Electricity and acquire a clearer understanding of the situation.

······o······

The report of the Blue Print case at Pittsburg did not appear in the *Western Electrician.* Did the office cat make a mistake and devour good matter, or is Mr. Sunny acting as assistant editor of our esteemed contemporary?

······o······

It has been some time since any announcement has been made of the proposed absorption of the Westinghouse Company by the General Electric Company.

Edison Will be Again in the Field.

"Electricity's" Opinion Confirmed.

The following, which is believed to be based on direct statements from Mr. Edison, is printed in the New Brunswick *Daily Times:*

"An interview with Thomas A. Edison was recently published in the *Inter-Ocean* of Chicago, to the effect that he has retired from the electrical business. This is not so. Mr. Edison told the reporter that he had disposed of his stock in the organization of speculators which acquired a controlling interest in the Edison General Electric Company. Since that period he has not turned over any of his recent inventions to that organization, but in a short time it is said that a new Edison organization will be completed by the great inventor, who will equip it with several wonderful inventions which will make a complete revolution of the present methods of lighting. A majority of the pioneers of the lighting business who have declined employment with the so-called Electric Trust are to be associated with Mr. Edison, whose new factories will be located in New Jersey."

Responsibility for the Wreck.

A New York Paper Assumes to Believe the Boston Story.

(From the Evening Advertiser.)

"It was an unlucky day for the Thomson-Houston people when they became connected with Edison Electric. The methods which have made the General Electric Company a byword and a reproach are the result of the Edison interest in the management. Before consolidation the Edison interests were noted for their loose methods of business, and ever since the influence of the Thomson-Houston people has not been sufficient to prevent these identical methods from ruining what might be a very prosperous concern. If the present attempts to force out the Thomson-Houston interest from the management ever succeeds it will be a great misfortune for the already unfortunate stockholders in the General Electric. They will lose not merely the connection with the Fort Wayne Company, but every other company that is worth anything. That a concern like General Electric, which paid dividends at the rate of 8 per cent. less than three months ago, should be reduced to staving off all payments as long as possible, and even letting indorsed notes go to protest, only paying them when they are pressed on indorsement, is a public scandal. It is the result of, vulgarly speaking, 'sloshing around' in business. The General Electric Company has made scores of times all sorts of unbusinesslike concessions to secure business from its competitors, and the inevitable results of crippled resources and a forcibly contracted circle of trade have followed."

General Electric.

What is Said of it Nowadays.

From the "Wall Street Daily News."

The fight that is going on inside the General Electric Company between the Boston interests, represented by the Thomson-Houston people and President Coffin, on the one hand, and the New York interests, represented by Drexel, Morgan & Co. and Director H. McKay Twombly, is reported to have now reached the acute stage, and to have precipitated the withdrawal from the combination of the Fort Wayne Electric Company, which is one of the largest of the subsidiary companies. In Wall Street the withdrawal is taken as expressing sympathy with the Boston people in the present fight with the New York people, and it is perhaps prompted further by the fact that during the financial difficulties of July and August the General Company refused to honor a draft made on them by the Fort Wayne Company for $15,000.

Must Stand on Its Own Bottom.

Official Press Agent's Statement.

As to rumors concerning the Fort Wayne Company, it is understood that although the General Electric and its friends own a controlling interest in the stock, the Fort Wayne Company must hereafter rely upon its own resources, which resources are believed to be sufficient for its maintenance without drawing upon the General Electric Company.

The Boston View is Not Our View.

From the "Boston Advertiser."

The public announcement by the G. E. people that hereafter Ft. Wayne must look out for itself may be regarded as a practical announcement that its dividends will be cut off. The company has been carried along by G. E. for a considerable time as a left-over from the old T. H. The burden has become too heavy and hereafter Ft. Wayne stockholders need not be over-surprised to see their shares going the way of Detroit Electric.

The Effect in Detroit.

From the "Detroit News."

If the Fort Wayne Company withdraws it will affect the Detroit city lighting plant. The Fort Wayne Company controls the use of the Brush and Thomson-Houston patents in Wayne County. With the withdrawal of the Fort Wayne people they will naturally begin fighting the Brush and Thomson-Houston people, who will remain in the Trust, and the Fort Wayne Company would forbid the lighting commission to use the Brush or Thomson-Houston apparatus.

Mr. Coffin's Reported Resignation.

From the "Mail and Express."

There was a private dispatch received from Boston to-day which said that although President Coffin has not resigned he admits that he entertains an idea of doing so.

Who Would "Amalgamate" With a Wreck ?

From the "Evening Post."

General Electric was advanced early on the purchase of a few hundred shares by a trader, but fell back when he attempted to sell. Reports are current that some interests favor amalgamating the concern with opposition companies in the hope that the announcement of a new deal would create a buying movement in the stock.

Rotary Mercurial Air Pump.

BY DR. F. SCHULZE-BERGE.*

Of the different types of mercurial air pumps which have been devised so far two have been introduced into practice on a large scale, viz., the Geissler and the Sprengel pumps. Both are represented in numerous modifications, and have undergone manifold improvements in the course of time. They produce vacua of the highest grade, but compared with the mechanical piston pumps both of them are under the disadvantage of working only very slowly, so that they do not appear fit for evacuating receivers of large volume.

On the other hand, even the most perfect of the mechanical air pumps are far behind the mercury pumps so far as the degree of the vacuum produced is concerned.

To combine the advantages of both systems my brother Hermann and I have together constructed the rotary air pump described below, which allows the creation of extensive vacua of excellent quality in a very short space of time.

PRINCIPLE OF THE ROTARY AIR PUMP.

We have carried out the apparatus in a number of different forms, all of which are based on the same principle.

The pump vessel is formed by a curved tube returning into itself, which revolves in constant direction around a stationary axis of rotation. A mercury piston passing through the interior of the tube creates on the one hand the vacuum and expels on the other hand the evacuated air, while the connections required by the pump vessel with the receiver and the atmosphere are effected by stopcocks or suitable valves.

Of the numerous modifications which may be given to the apparatus on this principle, some will be shortly explained in this report, whereupon a more detailed description will be given of the one which has proved to be the most serviceable for practical use.

RING-SHAPED STOPCOCK PUMP.

The play of the machine is particularly conspicuous in the stopcock pump, Figs. 1 and 2. The hollow ring P has a diameter of one meter or somewhat more, and an inner width of some centimeters. It is revolvable around the horizontal axis A, which is hollow and closed at one end, while the other end is airtightly introduced through the stuffing box S into the stationary tube R. To the latter tube is connected the receiver to be evacuated. Within the ring there is a quantity of mercury Q, sufficient to equilibrate the pressure of the atmosphere if this pressure acts upon only one of the shanks of the mercury.

A three-way stopcock H, similar to the well known Grassmann stopcock, is inserted into the circumference of the ring. The seat of the stopcock is connected to the hollow axle A by the tube r.

The stopcock occupies three different positions during the rotation of the ring. In the first one it allows free passage to the mercury, as in Fig. 1. In the second one it prevents any communication between the parts of the ring P and tube r on the atmosphere. In the third position it connects the end E_1 of the ring, with the atmosphere, and the end E_2 with tube r and the hollow axle A.

Let the ring be rotated in the direction of the arrow (Fig. 1) until all mercury has passed the cock, and then let the stopcock be given its second position separating the ring from tube r and the atmosphere. If after this the rotation of the ring is continued, the mercury column will follow the upward motion of the stopcock until the difference of its levels corresponds to the atmospheric pressure. If then the stopcock is moved into its third position, air will rush into the ring from the receiver through the axle. The same occurs when the rotation of the ring proceeds, while at the same time the air above level N_1 is expelled into the atmosphere. When the stopcock reaches the mercury level N_2, it is brought into its original position again, and the play of the pump is repeated similarly as described.

---

* Read before the International Electrical Congress, Chicago.

STOPCOCK PUMP WITH SPIRAL-PUMP VESSEL.

In the apparatus just explained the mercury only partly fills the volume of the pump vessel P in which the vacuum is created, and only a moderate quantity of mercury is required. A vacuum of very much larger volume may however be produced with the same quantity of mercury.

Suppose the pump vessel not to be formed of a single ring, as described above, but to have the shape of a double spiral, as in Fig. 3, the two ends of the spiral tube being joined by the stopcock H. If then the spiral is supplied with the same quantity of mercury as the ring in Fig. 1 the whole volume of the spiral may be evacuated by a continued rotation. While the play of the machine is in all essential respects identical with the one of the apparatus Fig. 1, the vacuum produced may be given an extent arbitrary within wide limits without increasing the quantity of mercury required.

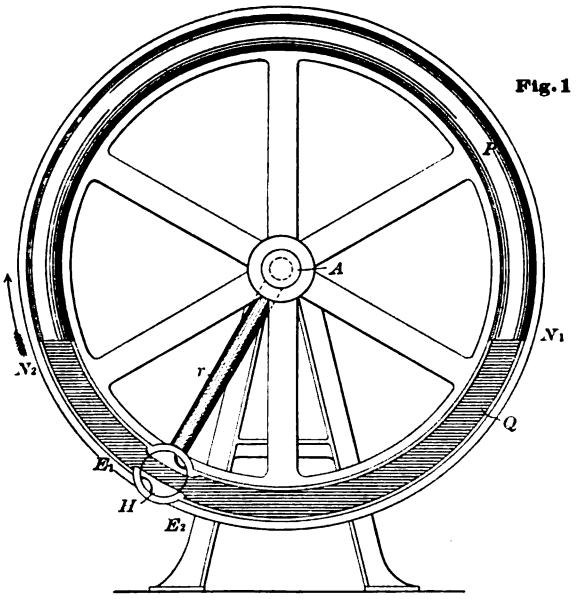

Fig. 1

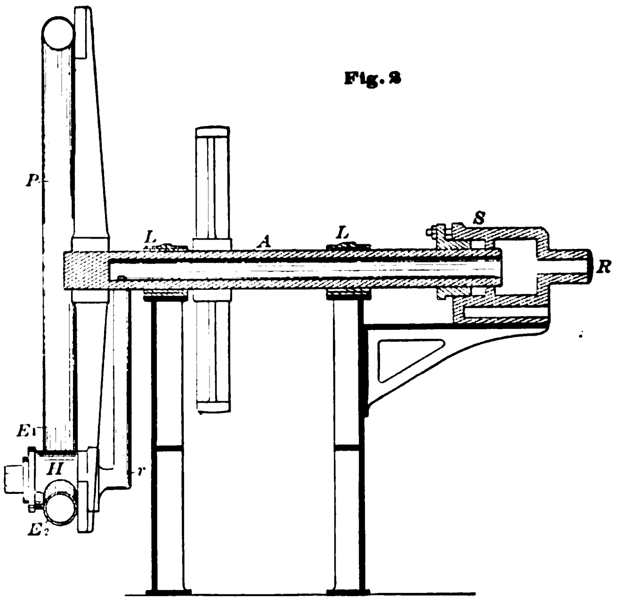

Fig. 2

RING-SHAPED VALVE PUMP.

The pump represented by Fig. 4 has, like the one in Fig. 1, a ring-like pump vessel on a horizontal axle. The apparatus is supposed to cooperate with an auxiliary pump (mechanical piston pump, water-jet air pump, etc.,) in such a way that the air exhausted from the receiver is not discharged by the ring into the atmosphere directly, but into a chamber in which a partial vacuum has been previously created by the auxiliary pump.

The place of the stopcock is here taken by the valve V, which is inserted into the circumference of the ring, and represents a spiral tube consisting of two convolutions. If the circumference of the ring be followed up in the direction of the hands of a watch it will be noticed that the convolutions of the spiral run from E_2 in the opposite direction until they return at E_1, into the ring P.

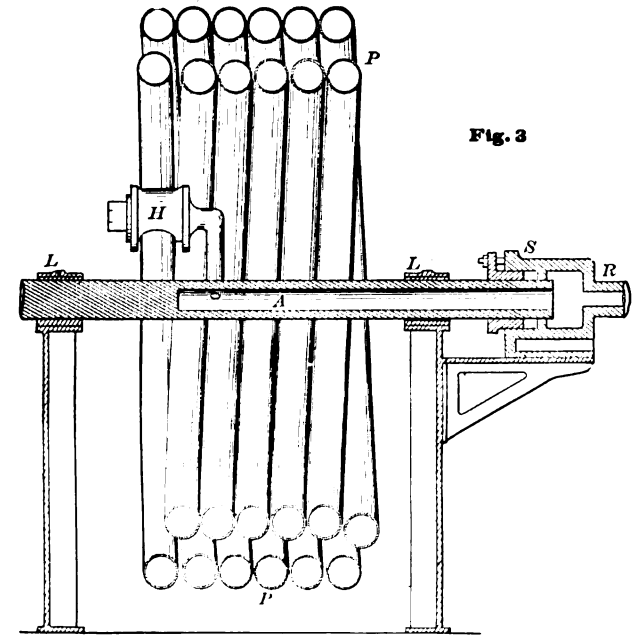

Fig. 3

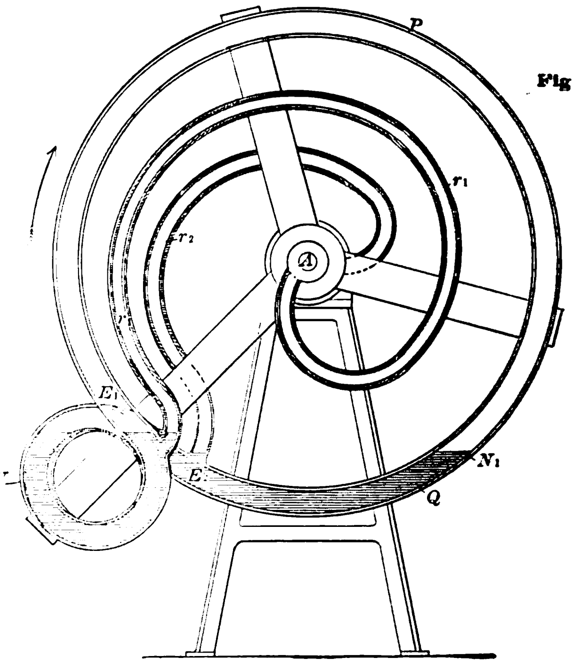

Fig. 4

The axle which in Fig. 4 is only shown in cross section projects as well in the front as in the back of the plane of the ring. It is hollow, and divided into two compartments by a vertical diaphragm in its middle.

Each end of the axle is connected airtightly through a stuffing box with a stationary tube in the same manner as the open end of the axle A in Fig. 2 is connected to R. The one in front of the ring leads to the auxiliary air pump, while the tube on the opposite side is connected to the receiver.

At E_2 the tube r_2 branches off from ring P and communicates with the receiver through the axial compartment situated at the back of the plane of the ring, while another tube r, starting from E_1, is connected to the auxiliary pump through the other compartments of the axle.

The spiral valve and a part of the ring are filled with mercury.

If the ring is rotated in the direction of the arrow, the air above it, level N_2, is expelled through r into the preliminary vacuum, whence it is removed by the auxiliary air pump. At the same time air is drawn from the receiver through tube r_2. This is repeated at each revolution of the ring.

The vacuum in the receiver is permanently separated from the one existing in the auxiliary air pump by the mercury contained in the spiral tube, provided that in the latter vacuum the pressure be kept so low that the difference of pressure of both vacua is equilibrated by the mercury of the valve. During every revolution a part of this mercury runs out into the tube r_1, but returns into the ring during the progress of the rotation. The width of r_1 therefore must be selected so great that the mercury running out of V never can fill the full cross section of this tube.

DOUBLE RING PUMP.

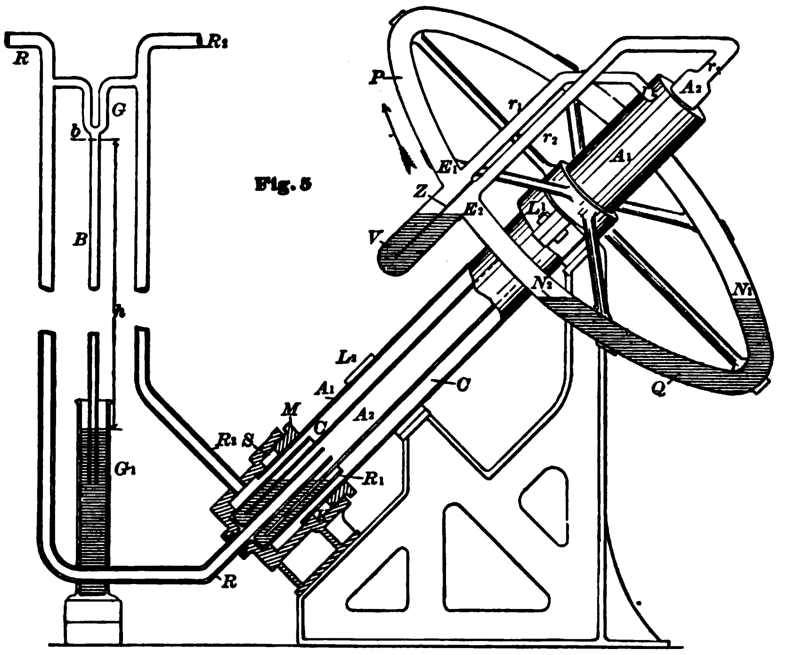
The greatest difficulty met with in the production of high vacua by rotary air pumps is caused by the necessity of establishing an absolutely and permanently air-tight joint between the rotary and the stationary parts of the pump. Without doubt this is the principal reason why the practical development and application of rotary pumps has not been carried out so far. It is impossible to create and maintain a high vacuum according to the notions of this day without a connection warranting perfect air-tightness between the receiver and the rotary parts of the apparatus. If, on the other hand, the receiver were to be rigidly connected with the pump, it would have to participate in the rotation of the latter, which only in rare cases would be practicable and recommendable.

While it is perfectly feasible to attain in the pumps described above the absolute air-tightness of the axle required, still we did not succeed so far in finding as simple a solution of the problem in those cases as the one embodied in the description of the apparatus illustrated by the Figures 5 and 6. This pump is distinguished by its easy manipulation, quickness of work and reliability of action, and appears equally adapted for laboratory work as for industrial purposes.

Also this apparatus is supposed to co-operate with an auxiliary pump which is used to create a moderate preliminary vacuum.

To facilitate the general view of the instrument, only one of the two ring-shaped pump vessels is shown in Fig. 5.

First, the arrangement of the axle is to be considered. It consists of the two concentric tubes A_1 and A_2. The larger tube, A_1, is mounted rotatably in the bearings L_1 and L_2, has an inclination of 40°, and projects with the lower end into the stationary stuffing-box, S. Through the bottom of S a tube, R, is introduced airtightly. The same is surrounded by the wider tube, R_1, as by a bell the mouth of which is turned upwards. The intermediate space be-



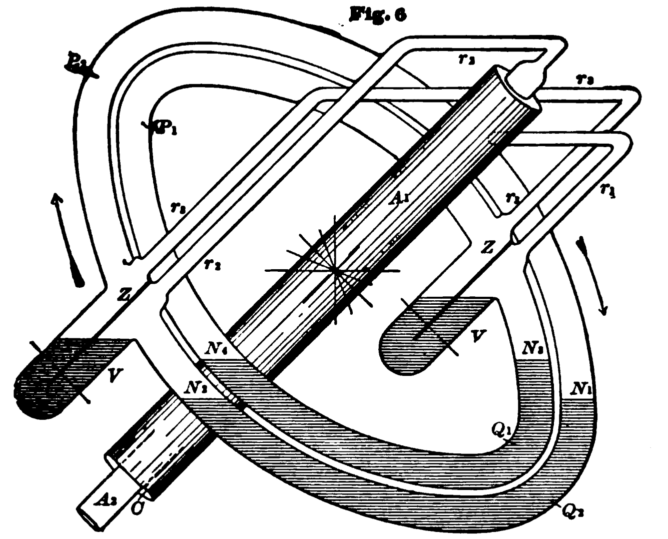
tween R and R_1 is provided with mercury. Into this space dips the inner axle tube, A_2, which passes air-tightly through the closed upper end of tube A_1, and rotates simultaneously with this tube. The tube R is to be connected with the receiver tube, R_2, with the auxiliary pump. These two tubes are connected by the forked tube G, which is so arranged that, after the vacuum is created, mercury may be introduced into the fork or withdrawn from the same by raising or lowering vessel, G_1.

The ring-like pump vessel, P, is fastened to the axle by six radial arms, and has an inclination of 45°. Into the circumference of the ring the valve, V, is inserted. It consists essentially of a cylindrical vessel closed at the bottom and parallel to the axis of rotation, which vessel is divided into two compartments by a tongue, Z, reaching nearly to the bottom of the valve. One of these compartments is connected to the middle tube, A_2, of the axle by tube r_2, while the second compartment communicates with the hollow space, C, contained between the walls of A_1 and A_2.

The valve, V, and about one-third of the circumference of the ring are filled with mercury, as illustrated in Fig. 5. If the ring is rotated in the direction of the arrow, the air contained above the mercury level, N_1, is expelled through tube r_1 and the channel C to tube R_2. At the same time air is drawn in the rear of level, N_2, through tubes r_2, A_2 and R into the pump vessel.

Let the receiver now be connected to R, and the ring vessel be placed into the position shown in Fig. 5, so that tube r_1 may freely communicate with the interior of the ring. Then the auxiliary pump is worked and the interior of the receiver and of the ring pump evacuated to such a degree as the auxiliary pump may be able to produce, say, for instance, to 10 millimeters of mercury pressure.

During this time the mercury rises up in the barometric tube, B, say to point b. Now vessel G_1 is raised so as to make the mercury enter the fork, G, thus interrupting the communication between R and R_2.



The level of the mercury contained between R_2 and R has not been changed by the preliminary evacuation, since so far the same pressure is acting within A_2 as in C.

If now the ring be rotated, air is drawn by the action of the mercury piston explained above, from the receiver into the ring through R, A_2 and r_2. On the other hand the air contained in the ring above N_1 is expelled towards the auxiliary pump through r_1, C and R_2, while the mercury contained in V permanently prevents a direct communication between the ends E_1 and E_2 of the ring.

The auxiliary pump now is only worked to the extent required for removing the air discharged from the ring, and to maintain in R_2 and the parts connecting with this tube the pressure originally created therein.

With each revolution of the ring the pressure decreases in A_2, while between A_2 and A_1 it remains essentially constant. Therefore the level of the mercury contained between A_2 and R will rise, while the level of the mercury between A_2 and R_1 must sink. The difference in level thus produced cannot become greater than the one corresponding to the difference of pressure between the preliminary vacuum created by the auxiliary pump and an absolute vacuum, i. e., not greater than 10 millimeters in the present case.

Of course the difference of pressure between the preliminary and the final vacuum is also manifested in the shanks of fork G, thus permitting the observer to watch the progress of the evacuation until the increase of the difference in level becomes inappreciable. For further observation a McLeod gauge is connected to R. We have used a modification of the same, shown in Fig. 9. The end of tube T connects with R. Raising and lowering the mercury in D is effected by the corresponding increase and decrease of air pressure in I. For that purpose the tube F is connected by a rubber tube to the auxiliary pump. A drying tube inserted into the rubber tube keeps the air in I free from moisture.

The stuffing box S only serves to protect the preliminary vacuum against access of atmospheric pressure so far as required. The purpose is attained by a number of greased leather washers K inserted into the stuffing box which can be compressed by the nut-screw M.

The separation of the final vacuum from the preliminary one is effected by the mercury contained between R_1 and R, and is accomplished thereby in a highly satisfactory manner. Even with the highest vacua attainable the seal proves absolutely reliable.

A seal based on the same principle may be used instead of the stuffing box S to separate the preliminary vacuum from the atmosphere. We have carried out this arrangement in several machines. It requires a somewhat greater length of the axle, but does away with the necessity of paying attention to a stuffing box, as in Fig. 5.

The pump which we found to be the best among the various apparatus constructed differs from the one represented by Fig. 5 in one point only, which, however, is of great practical importance. Instead of the single pump vessel, P, it contains two of them, viz., the concentric rings P_1 and P_2 (Fig. 6). They are so arranged that the air evacuated from the receiver during the rotation must pass through both rings in succession. First it enters through r_2 into the ring P_2 and is expelled during the next revolution by the piston Q_2 to r_3. Thus it enters the ring P_1 from which, during the following revolution, it is removed by piston Q_1 to r_2. Thence it is drawn off by the auxiliary pump in the same manner as in Fig. 5.

The vacuum created in P_1 in the rear of N_4 improves with each revolution. The consequence is that after the pump has been running for a short time the air withdrawn from the receiver by P_2 is discharged into a space already highly evacuated, viz., into the vacuum of ring P_1. The whole volume of ring P_2 and the mercury contained therein will therefore come into contact only with air of high rarefaction, which circumstance is of great importance if extreme evacuation is aimed at.

The pump does not require any manipulation except a single rotation. It therefore can be easily run by machinery. For that purpose there is space provided on the axle for a pulley, and for rotating the apparatus by hand wooden handles are used, forming prolongations of the six spokes of the frame.

By this pump vacua of so high a degree as to escape close measurement by the McLeod gauge have often been created. For that purpose of course it is necessary to provide for the absolute dryness of the mercury and of all parts of the pump and the receiver.

Fig. 7

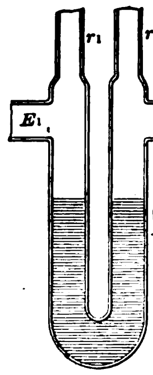


Fig. 9

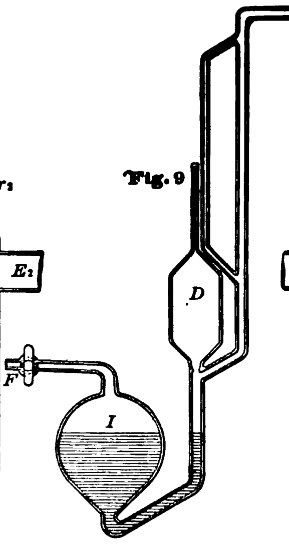

Fig. 8

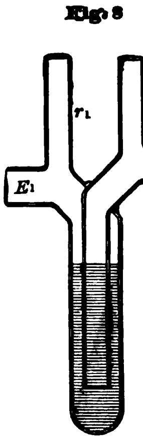


As drying material in producing high evacuation we have used metallic sodium with good success. It eagerly absorbs humidity, and while giving off hydrogen is covered with a layer of caustic soda. As the latter is highly hygroscopical, it adds efficiently to the drying action of the metal.

The vessel containing the sodium was, as a rule, connected to the rest of the system by a tube susceptible of being closed by a mercury seal.

A pump of the kind described in which the outer ring had a diameter of 60 centimeters and a capacity of 0.9 liter, permitted 15 revolutions per minute when rotated by hand. At present a larger machine for industrial purposes is in course of construction, in which the volume of the outer ring amounts to 8.5 liter.

In conclusion I wish to remark that besides the apparatus described quite a number of different modifications of the pump have been worked out, every one having its peculiar merits or advantages.

I do not hesitate to say that although more than a hundred years have elapsed since the construction of the first mercury pump, still I think that we are far from having fully realized the possibilities of perfection contained in this apparatus, and that we may expect valuable fruit from further work in this line, especially on account of the close connection of modern electrical research with the nature of high vacua.

American Street Railway Association Convention.

The twelfth regular annual meeting of the American Street-Railway Association will be held in the Hall of the Exposition Building, Milwaukee, Wis., the third Wednesday in October (the 18th), 1893.

Special committees will report on the following subjects: "Best Method of Lighting and Heating Street-Railway Cars," "Can the T Rail be Satisfactorily Used in Paved Streets?" "Direct Driven Generators," "Power-House Engines," "Standard Form for Street-Railway Accounts," "Standards for Electric Street-Railways," and "Storage Batteries in Connection with Central Stations for Utilizing Surplus Energy for Lighting or Power." Notice has been received by the secretary that a special paper will be read on the following subject: "Some Practical Points in the Construction of Underground Feeders."

The Executive Committee has secured the Milwaukee Industrial Exposition Building for the exhibition of supplies and manufactures of every nature used in the street-railway business. It has been engaged for two entire weeks, beginning October 9 and ending October 23, thereby giving ample time for the setting up and removal of the largest and heaviest exhibits. The hall for the meeting is also in the same building, on the second floor, and delegates will therefore be enabled to examine the exhibits with much greater satisfaction than heretofore. The exposition will be in charge of the secretary, assisted by Mr. A. Trumpff, secretary of the Milwaukee Industrial Exposition Association.

Death of a Western Union Superintendent.

Charles O. Rowe, superintendent at Pittsburg of the Western Union Telegraph Company, died on the 12th inst. at Titusville, Pa. He was born at Harper's Ferry, September 10, 1840. He was appointed Superintendent of the Eighth District in 1884. It includes Western Pennsylvania, Eastern Ohio, West Virginia and Maryland. Deceased leaves a widow and four children.

Legal Notes.

Several citizens of Manchester, N. H., have entered suit against the city for the purpose of breaking the contract between the city and the Manchester Electric Light Company. In May last the city and the electric light company threw up the then existing three years contract between them and made a new one for a period of ten years. By the new contract the city reduced the price paid for light from $137 to $115 per annum, and secured other concessions. The petitioners claim that ten years is too long a time for which to make a contract, and deny the city its right so to do.

The State Electric Light Company has petitioned the Supreme Court of Kings County for an order permitting the company to carry on its business in the city of Brooklyn. The petition specifies that contracts have been made which cannot be fulfilled; that consents to furnish lights, etc., have been secured, but that the company is unable to do business by reason of the laxity of the Board of Aldermen and of the committees to which the applications have been referred.

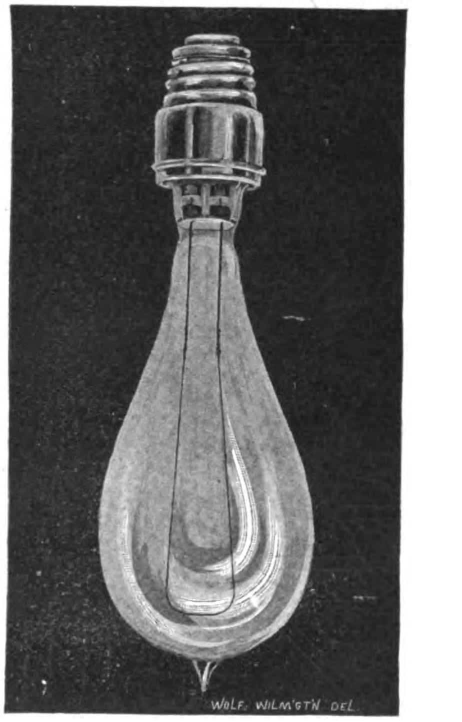
The "Maggie Murphy" Lamp.

Philadelphia's Aspirant for Popular Favor.

The accompanying cut is the fac-simile of the new "Maggie Murphy" lamp, which has just been brought before the public by the Pennsylvania Electric Engineering Company, Penn Mutual Building, Philadelphia.

The construction of the lamp, as shown by the illustrated cut, consists of a receiver made partly of glass and partly of cement. The cement is placed in the neck of the bulb, through which the leading-in wires pass. It was found in making the experiment with this cement that it was very difficult to overcome the softening of same, caused by the heat from the leading-in wires, two on each one, the same being insulated from each other by means of two mica plates, one above and one below. These discs radiate the heat from the leading-in wires to such an extent that disintegration of the cement stopper is impossible, and it is claimed the lamp is thus rendered the coolest burning lamp on the market.

The "Maggie Murphy" lamp is not identically the same lamp as was previously manufactured by this company, and does not infringe on the Edison patent, the special claims of which that were sustained being the combination of carbon, filamentary or threadlike in size and properly carbonized, used as an illuminant in an incandescent electric lamp, with the receiver made entirely of glass and the conductors passing through the glass, and from which receiver the air has been exhausted to such an extent that disintegration of the carbon, due to the air washing action of surrounding gases or to any other cause, is so far reduced as to leave the carbon practically stable.



WOLF. WILM'GTN DEL.

THE "MAGGIE MURPHY" LAMP.

In the "Maggie Murphy" lamp the receiver is not made entirely of glass, and the conductors do not pass through the glass. It is obvious, therefore, to anyone understanding what a patent means, that this new lamp does not infringe nor is it tributary to the Edison patent.

The appearance of a non-infringing lamp is a just cause for congratulation at this time, and the Pennsylvania Electric Engineering Company will have the best wishes of the entire trade.

Whatever the stagnation in general business, incandescent lamps must be bought, and it is a pleasure to announce further and effective opposition to the well-nigh established monopoly of the Electric Trust in this field.

Boston Notes.

The sudden death of Mr. F. L. Ames, Boston's wealthiest citizen, on board the Fall River steamer "Pilgrim" Tuesday night, caused somewhat of a flutter on the Boston Stock Exchange as soon as the news was known. Mr. Ames was a large holder of General Electric stock, and one of the heaviest underwriters in the new deal recently made with the Trust by the Traction and Illuminating Company. The stock sagged a point or two, as it was thought that his vast and varied holdings might, by the death of Mr. Ames, be divided up a good deal among the members of his family, but when it became known that such was not likely to be the flurry ceased. For a long time Mr. Ames's connection with the General Electric Company was a tower of strength to the moribund Trust, for not only was he at all times ready and willing to aid the directors when they found themselves in a tight place for ready money, by advancing it to them, but his splendid credit enabled the Trust managers to "raise the wind" at times when, but for the Ames credit, disaster, which has at last overtaken them, would have come upon them long ago.

For some time past the electric rail-welder built by the Thomson Electric Welding Company has been doing very satisfactory work on the tracks of the West End Railroad Company. Difficulties, however, have been encountered in the use of this machine, and it has been returned to the factory where it was built. It has been found that after being welded the rails break, not where they have been welded, but at other points, and this it is believed is the result of contraction. It is thought the difficulty will be overcome.

The Rockland and Abington Electric Railroad Company, which has become quite famous of late through its sanguinary conflicts with and victory over the Old Colony Railroad Company, is meeting with so great success that it has determined to double its capital and make it $120,000 so as to enable it to extend its system to South Weymouth. Thence it proposes to build to East Weymouth, and later it may push along to Hingham and beyond, to Nantasket Beach, Boston's most popular marine resort. There is a brisk demand for stock.

The handsome volume published under the title of "Armington & Sims Engine Company Catalogue, No. XVIII," is a work that every mechanical engineer ought to have in his possession and carefully study. As a book it is a work of art, being embellished with drawings of engines and separate parts superior to any we have ever seen before, while every page is replete with valuable data. Cuts are furnished of every type of engine designed and manufactured by this well-known firm. There is scarcely a use to which steam power is applicable but the Armington & Sims Co. have a special type of engine for. For electric light and power work these engines—single or double—have no superior and are in use in every part of the world. The makers claim for them the following advantages: extreme simplicity, the entire absence of parts requiring frequent adjustment, great regularity of speed, small cost, especially for the greater powers, small space required for engine and fly-wheel, a compact form and consequent rigidity in stationary and moving parts unattainable in engines of long stroke, the employment of short and nearly parallel belts in place of long converging ones, the avoidance of intermediate gearing to produce the speed required, the great saving in room, building and foundations. The large numbers of these engines now in use, both horizontal and vertical, the latter type being specially popular for running dynamos on shipboard, coupled with the extensive business now doing by the company is unmistakable evidence that the foregoing advantages are fully appreciated by users of steam engines the world over.

It is reported that the number of employees at the General Electric Company's factories in Lynn is being gradually increased, and that many of those who were laid off a few weeks ago are being notified to return to work. This will be welcome news to the work people themselves, many of whom have been reduced to great straits during the time they have been idle. Indications warrant the belief, however, that it will be a long time ere the factories are running full blast again, those now controlling the management of the Trust having determined that there shall be no more of the wildcat transactions such as were engaged in by the late management — transactions which largely brought about the present chaotic condition of the company's affairs.

It is a source of satisfaction to be able to report a gradual return of confidence in New England electrical circles and a better showing of business all round. Still trade is nothing like what it ought to be, and as we feel sure it soon will be, but after the serious depression of the last few weeks to be able to report any improvement whatever is a subject for congratulation.

The new electric power station that is being built by the Quincy and Boston Street Railroad Company at Quincy Point is now well under way. This company is one of the most prosperous outside of Boston. Since the introduction of electric light and railway, the quiet, conservative, sleepy, historic town of Quincy has taken on a new lease of existence.

Many of the Connecticut electric manufacturing companies are increasing their staff of men and running full time again.

At a recent meeting of stockholders in the Electric Gas Lighting Company of this city, Mr. W. W. Burnham, who for some time past has been assistant manager of that prosperous company, was appointed general manager in succession to his esteemed father, the late Mr. L. W. Burnham, who had by his untiring energy and push placed the firm in the very forefront of that class of trade. Mr. Burnham knows the business so thoroughly at home, and is so intimately acquainted with customers all over the country, that the same confidence will be felt by all in continuing their business relations with the company as heretofore. The same high grade goods only will continue to be manufactured and dealt in.

General News.

What is Going on in the Electrical World.

Staten Island.—Subscriptions are being solicited to defray the expense of extending the Prohibition Park electric road to Castleton Corners.

Los Angeles, Cal.—Bids for the franchise for an electric road between Los Angeles and Pasadena will be received by the Board of Supervisors up to October 4.

Detroit, Mich.—The Standard Electric Company of this city has just completed a storage battery system for F. W. Humphrey, clothier, of St. Louis, Mo., at a cost of $3,000.

Akron, Ohio.—R. J. Randolph, representing the Thomson-Houston interests, has been granted a franchise to construct a street railroad in this city and out to Cuyahoga Falls.

Lead, S. D.—The electric light plant of this city has been purchased by the Hulst & Price Lumber Company, who are already at work enlarging it to a considerable extent.

Utica, N. Y.—Extensive repairs are being made by the Central New York Telephone and Telegraph Company in the central office in this city with a view to bettering the service.

Meridian, Miss.—The directors of the Edison Electric Light and Power Company and those of the Meridian Street Railway Company have agreed to a consolidation of the two companies.

Rochester, Minn.—The council has definitely settled the contract for having electric lights here by approving the $5,000 bond of the Western Electric Company, which has the contract for the work.

Brooklyn, N. Y.—The Committee on County Farm has been authorized by the Board of Supervisors to advertise for proposals for the erection of electric light and kitchen fixtures for the four new buildings at Kings Park.

Fort Wayne.—The works of the Fort Wayne Electric Company, which have been closed for two weeks for repairs to machinery and buildings, have resumed operations with a full complement of workmen. The works employ 400 men

Philadelphia — The Hestonville Passenger Railway Company, who control twenty miles of track, are making arrangements to trolley their system and will begin work this month. About $500,000 will be needed to finish the work.

Pawtucket, R. I.—The Pawtucket Gas and Electric Lighting Company has closed a contract with the Union Railroad Company to furnish power for the operation of the electric car lines on Garden and Main streets between this city and Providence.

Sandusky, Ohio.—Indications point now to the speedy operation of the Sandusky, Huron and Milan Electric Road. At meetings of the stock and bond holders held lately, strong arguments were used and resolutions adopted in favor of the new enterprise.

Lynchburg, Va.—Conferences have been held lately between President Moon, of the Lynchburg Electric Company, and President Pettijohn, of the Rivermont Company, in regard to street railway extension in the city, and particularly to improving the transit facilities to Diamond Hill.

Manchester, Conn.—It is understood here that the Mather Electric Company, who have an extensive plant at North Manchester, will be able to compromise with their creditors, and that the works will be started up as soon as the demand for the goods will necessitate a resumption of work.

Baltimore. — The City Passenger Railway Company has awarded the contract for eight boilers for the equipment of the new electric power house on Light street to the Campbell-Zell Company. The contracts for the engines had previously been awarded to the Allis Company of Milwaukee.

Cincinnati.—President Kilgour, of the consolidated electric lines, has established a school for the instruction of applicants for employment on the lines in the mysteries of electricity, touching the various appliances on electric cars, how to use the machinery, and the best method of procedure in perplexing circumstances to avoid accidents.

Syracuse, N. Y.—Following the Salina street line, the Wolf street line will be the next to change its motive power to electricity. Other lines will be equipped as soon as the company can make arrangements for the work.—The Syracuse Railroad Company has lately mortgaged its property to the State Trust Company of New York for $2,500,000.

Millville, N. J.—The Millville Rapid Transit Company has succeeded in obtaining consent of council to construct a trolley road in this city. The road will be part of the system connecting Millville and Bridgeton, of which George Wood, president of the Millville Manufacturing Company, is the principal owner.

Newark, N. J.—The dispute between the Consolidated Traction Company and the Delaware, Lackawanna and Western Railroad Company as to the right of the traction company to string wires across the D. L. and W.'s tracks at Clinton avenue has been decided in court in favor of the traction company.

St John, N. B.—Col. W. S. Rogers, of Cleveland, Ohio, special agent of the Brush Electric Company, was in this city a few days ago. It is the intention of the company to locate a branch of their business somewhere in Canada, and Col. Rogers is to select a site. He will visit several other cities before making any arrangements.

Gloversville, N. Y.—The directors of the Gloversville Electric Company have elected the following officers: President, James Radford; vice-president, John Marsh; secretary, Edgar A. Spencer; corresponding secretary, Paul T. Brady; treasurer, Lee B. Crittenden; superintendent and manager, John Begley.

Cleveland, Ohio. — The Cleveland Electric Railway Company has filed a deed of trust in favor of the Central Trust Company of New York, including its 92½ miles of railway track, its buildings, etc. The mortgage is to secure the issuing of $1,900,000 of the $3,500,000 bonds authorized at a meeting of stock holders on August 31.

Ansonia, Conn.—The *Sentinel* says: "The resumption of work at Wallace & Sons lightens the feeling of depression which had fallen upon Ansonia. There is every probability that at the former shop the few departments yet idle will soon be started up again, and within a month or two at the most a greater activity will be brought back to us once more."

St. Louis.—The Belleville and St. Louis Railroad Company has brought suit in the Circuit Court, in the nature of a vender's lien, against the Belleville City Railroad Company for $80,484.88.—The General Electric Railway Company of Chicago will commence in October the laying of a double track electric railway in Belleville, and expect to have it completed and in operation by spring.

Hoboken, N. J.—The Paterson, Rutherford, Jersey City and Hoboken Electric Railroad is expected to be in operation by New Year's Day. Manager Debevoise of the North Hudson Elevated Railroad has, it is said, accepted a similar position on the new road. The Crimins syndicate will in all probability purchase the entire North Hudson system.

Trenton, N. J.—The Associated Electric Company of New Jersey at its last meeting declared a dividend of 2 per cent. on the paid up stock on the six months' earnings of the district telegraph service. J. Wallace Hoff, the present secretary and treasurer, was elected secretary and general manager, and Harry G. White, of the Trenton Light and Power Company, was made superintendent and treasurer, to look after the company's local interests.

Camden, N. J.—The trestle on the Timber Creek section of the Camden, Gloucester and Woodbury Electric Railway is 3,400 feet long, and is said to be the largest of the kind used by any electric railway in the world. The initial trip over the road was made a few days ago, and was enjoyed by a number of prominent men interested in the road and several Woodbury officials. The line is finished to Fancy Hill, within a few miles of Woodbury, where it is proposed to establish a beautiful pleasure resort.

Buffalo, N. Y.—The F. P. Little Electrical Supply and Construction Company of this city has been awarded the contract for enlarging the electric light plant of the St. Lawrence State Hospital at Ogdensburg. The contract amounts to about $13,000.—At a late meeting of the stockholders of the Buffalo, Kenmore and Tonawanda Electric Railroad Company, D. F. Calal an was elected president, Norman E. Mack vice-president, and John L. Donovan secretary. It was reported that the road would soon be finished and in operation.

Lawrence, Mass.—The aldermen have been discussing the question of installing a municipal lighting plant in Lawrence, and have turned the matter over to a special committee, including the mayor. At the last meeting of this committee the mayor read reports from various cities and towns throughout the country where municipal lighting plants have been established. The results in several places were unsatisfactory, and in others it was shown that a municipal plant was an expensive luxury. There were places, however, where municipal plants had proven a success and the citizens were enjoying the benefits of excellent service at low rates.

Albany, N. Y.—The day fixed for closing the filing of applications for experimenting in electrical propulsion on the canals (Sept. 8) has been extended to October 1. The promoters of the "Geer" device, the idea of a Rochester man, have applied for half of the $10,000 appropriation made by the Legislature, to be given to the inventor of this device, to enable him to give a public exhibition of it, and as there is a doubt as to the proper distribution of the appropriation, the Superintendent has determined to lay the matter before the Attorney-General for his decision.

New Haven, Conn.—The New Haven Street Railway Company has secured control of the State Street and Morris Cove Railroads, in pusuance of its purpose to consolidate the local street railway systems. The Saltonstall road, to be built next summer, is included in the scheme. All the roads will be electrically operated. The officers of the New Haven Company are: President, David Corey, of New Haven; vice-president, Charles A. Warren, of New Haven; secretary, treasurer and general manager, G. A. W. Dodge, of New Haven; directors, in addition to those named, Thomas Krutz, of New York; Thomas M. Waller, of New London; S. Harrison Wagner, James J. Lawton, William J. Atwater and Eli Whitney, Jr., of New Haven.

The Milwaukee Convention.

The exhibit of apparatus at the twelfth annual exposition of the American Street Railway Association at Milwaukee in October bids fair to surpass that at Cleveland last year. Thus far space has been secured by the following exhibitors :

- Standard Railway Supply Company, Chicago, Ill.
- American Fluoride Company, New York, N. Y.
- Baltimore Car Wheel Company, Baltimore. Md.
- New Process Raw Hide Company, Syracuse, N. Y.
- Dorner & Dutton, Cleveland, O.
- Short Electric Railway Company, Cleveland, O.
- Sperry Electric Railway Company, New York, N. Y.
- General Electric Company, New York, N. Y.
- Wadhame Oil and Grease Company, Milwaukee, Wis.
- Fitzgerald-Van Dorn Company, Lincoln, Neb
- Peckham Motor, Truck and Wheel Company, Kingston, N. Y.
- Eureka Tempered Copper Company, North East, Pa.
- Fulton Foundry Company, Cleveland, O.
- Steel Motor Company, Cleveland, O.
- Automatic Car Brake Company, Grand Rapids, Mich.
- J. G. Brill Company, Philadelphia, Pa.
- Siemens & Halske, Chicago, Ill.
- Stanwood Manufacturing Company, Chicago, Ill.
- Rochester Car Wheel Company, Rochester, N. Y.
- National Electric Manufacturing Company, Eau Claire, Wis.
- E. F. de Witt and Company, Lansingburgh, N. Y.
- Meaker Manufacturing Company, Chicago, Ill.
- Graham Equipment Company, Boston, Mass.
- Jewell Belting Company, Hartford, Conn.
- Sterling Supply Company, New York, N. Y.
- Time Transfer Printer Manufacturing Company, Pittsburg, Pa.
- International Register Company, Chicago, Ill.
- St. Louis Car Company, St. Louis, Mo.
- Lewis & Fowler Manufacturing Company.

The Western Electrical Supply Company of Omaha.

The Western Electrical Supply Company of Omaha, Neb., is a new concern which purchased the entire assets of the Western Electrical Supply Company, an Illinois incorporation, formerly doing business in Omaha. The officers are as follows : President, W. H. McKinlock ; secretary, John T. Burke ; treasurer, George W. Johnston. W. H. McKinlock was instrumental in the formation of the Central Electric Company of Chicago, and has been for years long and favorably known in the electrical fraternity. John T. Burke, the secretary, was very closely identified with the telephone interests in the early days. He was for eleven years with the Nebraska Telephone Company, and during that time had a very wide and diversified experience in this branch of the electrical work. Since that time for five years he was superintendent of construction for the old Midland Electric Company of Omaha, and in that capacity installed many of the central stations and isolated plants erected in that section of the country. For the past three years Mr. Burke has been an electrical engineer and contractor, with offices in Omaha, and has completed some very large contracts for the complete installation of electrical plants, and also for electric wiring. G. W. Johnston, treasurer of the company, has had a wide experience in the electrical supply business. He was one of the founders of the Gate City Electric Company of Kansas City, Mo., and held the position of secretary and treasurer of that company for several years, after which he accepted the position of general traveling representative of the Central Electric Company of Chicago. The Western Electrical Supply Company of Omaha is the Western agent for many well known electrical specialties, including the International Okonite Company, Interior Conduit and Insulation Company, Eddy Electric Manufacturing Company, American Electrical Manufacturing Company, Burke automatic lightning arresters, Hart switches and Meston alternating fan motors. The company is receiving orders from the South and East, and is constantly receiving orders from the far West, and it recently shipped an entire installation, including engine, dynamo, necessary wire, lamps, sockets, etc., to Chihuahua, Mexico. The company is very strong financially, and with the stockholders as active managers it is bound to succeed. It is always upon the lookout for new specialties, and is always glad to contract for anything of merit.

COMMERCIAL PARAGRAPHS.

The Model Dynamo-Motor made by the Elbridge Electrical Manufacturing Company, Elbridge, N. Y., is a very ingenious machine, and is specially adapted to the use of students and other experimenters. The price is moderate, and it ought to be a good line for any supply house to handle.

Whenever you see a switchboard which is really a work of art, the probabilities are that the marble came from the quarries of Mr. Edward Bonville at Fair Haven, Vt. He is the leader in this branch of the trade.

The United Electric Improvement Company of Philadelphia, who have been working for some time on new types of apparatus, will soon be ready to make announcements of interest to every one in the trade.

The Columbia Lamp Company of St. Louis, although running their factory night and day, are away behind with their orders and are building an addition to their factory which will double their capacity.

Many of the former users of the original Sunbeam lamp have availed themselves of the present opportunity to lay in a stock for the season. Both the old Sunbeam and the new Sunbeam lamps are now on sale.

Messrs. Palmer Bros., Mianus, Conn., whose fan motors are so well spoken of, make a specialty of motor attachments for sewing machines, etc.

The Riehle Bros. Testing Machine Company, of Philadelphia, have issued their Catalogue No. 8 in two volumes, which is a very good idea. The list of customers who are using these testing machines is a formidable one, and is proof positive of their reliability.

The Washington Carbon Company, of Pittsburg, which makes a specialty of motor brushes, reports a decided picking up in this branch of the business.

The Campbell & Zell Company of Baltimore report that they have closed within the past thirty days the following contracts for the Zell Improved Water Tube Safety Boilers, aggregating over 5,000 horse-power : The Illinois State Penitentiary, Joliet, Ill., 1.212 H. P.; the Illinois State Reformatory, Pontiac, Ill.; 600 H. P.; the new Stock Exchange, Chicago, 1,000 H. P.; the Bureau of Engraving and Printing at Washington, 516 H. P.; the Baltimore City Passenger Railway Company, 2,000 H. P.; and the Consolidated Gas Company, Baltimore, 250 H. P.

The Railway Equipment Company.

The Worcester (Mass.) Consolidated Street Railway Company, being equipped entirely with the type "G" and other material manufactured by the Railway Equipment Company, Chicago, writes to the latter company as follows:

Worcester, Sept. 3, 1893.

W. R. MASON, ESQ., General Manager,
Railway Equipment Co., Pullman Bldg., Chicago.

Dear Sir : We have about completed our overhead work and it ought to be a big advertisement for your company, as we have the most perfectly equipped road in the country. Every part is *first class.*

Truly,
JNO. N. AKARMAN,
General Manager Worcester Consolidated St. Ry. Co.

INCORPORATIONS.

The Bronx Gas and Electric Company, Westchester, N. Y.—to manufacture and sell gas and electricity for lighting purposes. Capital stock, $500,000. Promoters : Chas. H. Usher and James McGee, Brooklyn, N. Y.; Elias W. Taylor, Unionville, L. I.

The Elliott Electric Company of Cleveland, Ohio, has changed its name and will hereafter be known as the Elliott-Lincoln Electric Company. The capital stock of the company has been increased from $40,000 to $75,000.

In the U. S. Senate last week Mr. Cullom introduced a bill to incorporate the Washington Central Railway Company and to authorize them to use any motive power upon their line except steam. This authorizes the use of the trolley. The incorporators of the proposed road are M. I. Weller, T. H. N. McPherson, S. S. Yoder, Nathaniel McKay, John H. Knight, H. H. Rand, T. M. Ferrell and George W. Boyd.

The Universal Electric Pull Socket and Switch Company of New York City. Capital stock, $20,000. Directors : John M. Wellbrook, of Brooklyn : Louis Stirn and Maurice Sonborn, of New York City.

The Augusta Electric Company, Jersey City, N. J.—to build and maintain plant or plants for electric lighting, heat or power. Capital stock, $25,000. Promoters : F. B. Poor and L. C. Harris, Hackensack, N. J.; A. L. Furnald, Brooklyn, N. Y.

A charter has been filed with the Secretary of State, Kansas, for an electric railway, to run from Junction City to Fort Riley, the capital stock being $100,000. The directors are ex-Senator John K. Wright and A. L. Barnes, of Junction City, J. S. Gibson, E. S. McAnany and D. H. Irwin, of Kansas City, Kan. The same parties filed another charter for the Junction City Electric Light, Power and Milling Company.

The Cumberland Valley Electric Passenger Railway Company, capital $500,000, has been chartered at the State Department at Harrisburg. The line will traverse ten streets of Carlisle, and thence to Boiling Springs. The incorporators are Oliver H. Ormsby, S. Ritter Ickes, W. J. Ickes and S. H. Nigton, all of Altoona.

The Pall Mall Electric Association (incorporated in W. Va.), New York City—to manufacture, buy and sell electric curative and other goods worn upon the human body. Capital stock, $20,000. Promoters: Ruth E. Scott, Georgiana Scott, John H. Hawkins, all of New York City.

The Roseburg Electric Light and Power Company, Seattle, Wash.—to engage in public lighting and heating, and to furnish power by electricity, operate telephones, railways, etc. Capital stock, $20,000. Promoters : H. E. Clements, W. J. Grambs, Seattle ; S. Z. Mitchell, Portland, Ore.

The Electric Improvement Company, Jersey City, N. J. —to manufacture electric light, heat and power and electric supplies of all descriptions. Capital stock, $10,000. Promoters : R. Ashley, C. J. Shepard, Philadelphia ; F. Bell, Jersey City.

The Edinboro and Erie Railroad Company, Erie, Pa.—to construct and operate an electric railway in Erie. Capital stock, $200,000. Promoters: H. P. Van Dusen, Chas. S. Curtice, George W. Fuller.

The Morristown, Bridgeport and Conshohocken Traction Company, Norristown, Pa.—to construct and operate motors and cables and other machinery for supplying motive power to passenger railways. Capital stock, $10,000. Promoters: Edward S. Perot, Hiram R. Rhoades, Henry Freedly.

The Citizens' Electric Light, Heat and Power Company, Lykens, Pa.—to supply light, heat and power by electricity to the public in Lykens, Dauphin County. Capital stock, $10,000. Promoters: J. B. Whitney, F. J. Douden, J. J. Nutt.

The Scranton and Pittston Traction Company, Scranton, Pa.—to construct and operate motors and cables or other machinery for supplying motive power for passenger railways. Capital stock, $1,050,000. Promoters: W. F. Sadler, Lemuel Amerman, Chas. H. Mullen.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED AUGUST 29, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

504,042. Electric Circuit for Controlling Trains. Frank E. Kinsman, Plainfield, N. J. Filed Jan. 11, 1892.

504,104. Electric Conduit for Railways. Joseph I. Conklin, Brooklyn, N. Y. Filed May 2, 1892.

504,113. Electric-Railway Trolley. Alexander Pomroa, Lynn, Mass., assignor of one-half to Varna J. Peirce, Hudson, Me. Filed Sept. 1, 1892.

504,132. Means for Transmitting Power from Car-Axles to Dynamos. Morris Moskowitz and Samuel Young, Newark, N. J., assignors of one-half to Leon D. Adler and Joseph Loewenberg, same place. Filed April 29, 1893.

504.255. Electric-Railway Trolley. Frank J. Sprague and Patrick F. O'Shaughnessy, New York, N.Y., assignors to the Sprague Electric Railway and Motor Company, same place. Filed Jan. 19. 1889.

504 276. Crossing for Electric Railways Jay Nelson, St. Louis, Mo., assignor of one-half to Thomas C. White, same place. Filed May 18, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

504 082. Hanger for Electric Lights. John P. Hebendahl, Weatherby, Pa. Filed Nov. 5, 1892.

504.105. Manufacture of Carbon Rods for Electric Arc Lamps. Ehrenfried Corleis and Hermann Renisch, Essen, Germany, assignors to the firm of Fried. Krupp, same place. Filed April 26. 1893.

504,271. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 9. 1893.

504,277. Electric-Arc Lamp. William A. Phillips, U. S. Army, assignor of one-half to Thomas J. Porter, Miles City, Mont. Filed June 3, 1893.

DYNAMOS, MOTORS, ETC.

504,177. Brush for Dynamos or Electric Motors. Frederick H. Sandherr, St. Louis, Mo. Filed Jan. 7, 1893.

504,216. Regulator for Dynamo-Electric Machines. John C. Henry, New York, N. Y. Filed April 29, 1892.

BATTERIES.

504,130 Electric Battery. Hosea W. Libbey, Boston, Mass. Filed Sept. 15, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

504,011. Automatic Telephone. Josef Wratitsch and Stefan Gergacsevics, Graz, Austria-Hungary. Filed April 18, 1892.

504,108. System of Telephonic Intercommunication, Frank R. Colvin, New York, N. Y. Filed Feb. 6, 1893.

504.250. Telephone-Exchange Testing Apparatus. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1889.

504,251. Vibrating Circuit-Breaker, and Retardation-Coil for Test Systems. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed March 4, 1891.

SWITCHES, SWITCHBOARDS, ETC.

504,123 Circuit-Switch. Charles E. Dey, Denver, Colo. Filed Dec. 13, 1892.

504,160. Rheostat. Albert B. Herrick, Schenectady, N.Y., assignor to the General Electric Company, Boston, Mass. Filed July 22, 1892.

504,219. Multiple Switchboard Keyboard Apparatus. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 6, 1887.

MISCELLANEOUS.

503,981. Signaling Apparatus for Railways. John Orme, London, England. Filed Dec. 6, 1892.

504,059. Insulator. George W. Blackburn, Palmyra, N. J. Filed Aug. 30, 1892.

504,087. Electric Bowling-Alley. Pehr P. Nelson, New York, N. Y. Filed Sept. 21, 1892.

504,095. Electric Clock. Emil Schweizer, Sumiswald, Switzerland. Filed July 16, 1892.

504,148. Push-Button. William H. Berrigan, Jr., New York, N. Y. Filed April 7, 1892.

504,196. Electric Indicator. Jay L. Bradley, St. Louis, Mo. Filed Feb. 4, 1893.

504,200. Art of Concentrating Magnetic Iron Ores. Gurdon Conkling, Glens Falls, N. Y. Filed Sept. 30, 1891.

504,286. Dynamometer. Henry C. Stone, Kansas City, Mo., assignor to Olive A. Stone, South Evanston, Ill. Filed Dec. 27, 1892.

504,312. Coin-Controlled Race-Course. Charles Carroll, New Orleans, La., assignor to the Automatic Machine Company, Limited, same place. Filed Aug. 29, 1891.

ELECTRICITY.

VOL. V. NEW YORK. SEPTEMBER 27, 1893. CHICAGO. No. 11

ATTENDANTS AT THE ROCHESTER CONVENTION. (SEE PAGE 126.)

The Rochester Meeting.

The Eleventh Annual Meeting of the Street Railway Association of the State of New York was held in the rooms of the Chamber of Commerce, Rochester, N. Y., on September 19.

In the absence of the president, Mr. C. D. Wyman, who was detained at the World's Fair, Mr. D. C. Hasbrouck, the vice-president, took the chair and made the opening address.

The report of the Executive Committee was presented. The report showed that five companies had joined during the year. Three companies had been consolidated with a member company, leaving the present membership twenty-eight companies.

Reference was made to the subject of electric traction, in which the committee said: "We are glad to note the rapid development of the overhead system in Brooklyn. An object lesson as to the character of construction, equipment and operation by electricity is there being given to the country and the world at large that will do much to pave the way for the successful introduction of electric traction in those cities where it has not yet obtained a foothold."

The committee congratulated the fraternity that during the last session of the State Legislature not a single bill aimed at the successful operation and conduct of the business had become a law. All that was asked for the business was that the same consideration and fair treatment be extended to it as to any other business.

The business outlook was touched upon as follows: "The street-railway business is a delicate financial meter that indicates with certainty the financial condition of a people. In proportion to the prosperity of the people is our business successful; and the converse is equally true. Judged by this infallible test, therefore, we are assured that the worst of the country's financial troubles and business depression is passing away."

In closing the report, a fitting tribute was paid to the memory of the late John Stephenson.

The Treasurer's Report was presented and showed the financial transactions during the year:

Receipts	$902.49
Expenses	678.66
Balance on hand	$223.83

A report on "Recent Improvements in Cable Traction" was on the programme, to be presented by Mr. George W. McNulty, engineer of the Broadway cable road of New York City. The report was not ready, and Mr. McNulty sent a letter, in which he said:

"The 'improvements,' as you kindly call them, are yet practically not tried, or at least insufficiently so. It is true that the road has been running for several months, but with a view of meeting the public demand for better traveling facilities as soon as possible, and of experimenting a little with some devices before putting them in final shape, we really started before we were entirely ready. While the event has, I think, justified the wisdom of our course, it has naturally led our friends to assume that everything is done, and that we are sitting back in our chairs and contemplating the result of our labors with calm satisfaction. While we have no reason to be dissatisfied, we are certainly not done, and unfortunately for present purposes it is mainly our 'improvements' that are yet unfinished or at least untried. This of itself would make me reluctant to speak of what we have done as 'improvements' until they are proved to be so, but if further excuse were necessary, it would, I am sure, be sufficient to remind you of the multifarious and urgent matters that must engage the attention of one who has to get in complete running order a work of such magnitude and complexity to the exclusion of everything else, even so congenial a task as a contribution to the work of the Street Railway Association. I can safely promise a paper for next year."

The next business was the report of Mr. T. J. McTighe, "Return Circuit for Electric Railways," which was read by the secretary.

The vice-president appointed Messrs. Watson, Richardson, Sr., and Williams the Nominating Committee.

The committee recommended the following gentlemen as officers of the association for the ensuing year:

President, D. C. Hasbrouck, New York City.

1st Vice-President, G. Tracy Rogers, Binghamton.

2d Vice-President, James H. Moffat, Syracuse.

Secretary and Treasurer, W. J. Richardson, Brooklyn.

Executive Committee, John N. Beckley, Rochester; Daniel F. Lewis, Brooklyn; Charles Cleminshaw, Troy.

The association then adjourned to meet in Syracuse the third Tuesday in September, 1894.

The following delegates were present:

G. Tracy Rogers, president Binghamton Railroad Company, Binghamton; William Richardson, ex-president, and William J. Richardson, secretary, Atlantic Avenue Railroad Company, Brooklyn; Henry M. Watson, president Buffalo Railroad Company, Buffalo; W. W. Cole, general manager West Side Railroad Company, Elmira; H. Bergholz, secretary and treasurer Ithaca Street Railway Company, Ithaca; D. C. Hasbrouck, secretary Houston, West Street and Pavonia Ferry Railroad Company, New York; C. A. Williams, secretary, William Rosborough, superintendent, and Albert Green, electrician, Rochester Railway Company, Rochester; C. A. Durr, general superintendent Rochester Electric Railway Company, Rochester.

The Entertainment.

Rochester Treated Her Guests Royally.

After the close of the business sessions of the Association the visitors were well taken care of by the courtesy of the Rochester Railway Company.

There was an excursion to the lake over the new electric line on the east bank of the Genesee River, which involved a visit to the huge brewery of the Bartholomays, where an electric fluid of low potential was freely dispensed along with a substantial lunch.

LAF. HEIDELL.

Arrived at the lake the first thing on the programme was the taking of the photograph which is seen in our Frontispiece. Then came a magnificent banquet in the dining-room of the Cottage Grove Hotel. Many toasts were drank and responded to briefly by Mayor Curran, on behalf of the city of Rochester, and by Mr. W. J. Richardson and others of the guests. Songs were sung by the Tremont Quartette and good stories (also bad ones) were told by Mr. Laf. Heidell.

Major Evarts distinguished himself by bagging an order for six miles of Simplex wire, and others of the supply men were fortunate in a less degree.

Mr. Gregory, of the Yates, Syracuse, was on hand, and with the aid of General Harry Evans secured the Convention for next year. The choice was a wise one. Syracuse is a good town to visit, and the Yates is on a par with any hotel in the State.

Other than the regular delegates to the Convention, the attendants included the following gentlemen:

J. H. Stedmann, the "Transfer" man, Rochester.
R. Gerry, of Jones & Laughlins, Pittsburg.
H. W. Blake, *Street Railway Journal*.
F. R. Colvin, *Electrical Engineer*.
B. E. Greene, ELECTRICITY.
W. J. Clark, General Electric Company, New York.
J. S. Crider, Washington Carbon Company, Pittsburg, Pa.
Major H. C. Evans, Johnson Company, New York.
Major D. T. Evarts, General Manager Simplex Electric Company, Boston.
Thomas H. Fearey, General Electric Company, Buffalo.
Arthur W. Field, Peckham Motor Truck and Wheel Company, Kingston, N. Y.
R. Gerry, American Iron and Steel Company, New York.
H. J. McCormick, Schaffer Manufacturing Company, Rochester, N. Y.
Elmer P. Morris, General Electric Company, Indianapolis, Ind.
A. D. Newton, Eddy Manufacturing Company, Windsor, Conn.
J. F. Ostrom, Pennsylvania Steel Company, Philadelphia, Pa.
D. W. Pugh, John Stephenson Company, New York.
John S. Pugh, Baltimore Car Wheel Works, Baltimore.
F. C. Randall, J. G. Brill Company, Philadelphia.
F. D. Russell, Rochester Car Wheel Works, Rochester, N. Y.
John Taylor, Taylor Electric Truck Company, Troy, N. Y.
A. C. Vosburgh, Secretary New Process Raw Hide Company, Syracuse, N. Y.
H. W. Weller, General Electric Company, New York.
C. B. Wyman, Manager Central Electric Heating Company, New York.

All Creditors Will Have an Equal Show.

A receiver has been appointed to take charge of the affairs of Alexander, Barney & Chapin, who were closed up a few weeks ago on an execution obtained by Patrick Gray on assigned claims of Luke A. Burke.

Edward E. Denniston.

Mr. Edward E. Denniston, whose death at his home in Philadelphia was announced last week, was greatly interested in street railroads and a stockholder in many. Manager Littell of the Buffalo Railway Company speaks of him as "a fine business man, broad minded and liberal and full of energy. He was the controlling spirit in purchasing, extending and improving the street railroads in Buffalo, Rochester, Louisville, Columbus, Ohio, Brooklyn, Paterson, N. J., New Orleans, Worcester, Lynn, Boston, Chelsea, Scranton and many other cities, and he was a director of the street railroads in all of these cities. He was of great service to Buffalo in helping to bring about the change and improvement in the street railway system here."

Forming an Electrical Society at Toledo.

At a meeting of the electricians of Toledo, held on the 18th inst., a committee was appointed to draught a constitution and by-laws for a proposed society for the study of electricity and for electrical research. The following were chosen as members of the committee: Messrs. Faben, James Robinson, J. W. Cherry, DeBree, Dodge, Cline, McNamar, Dr. North and Prof. Waite of the Manual Training School. After the appointment of the committee, Messrs. Seagrave, North, Battelle and Professor Waite spoke briefly on the advantages of an electrical society.

The Ferris wheel at the World's Fair has paid for itself and is now clearing about $8,000 daily for its owners.

Long Distance Transmission.

Multiphase Motors.*

Mr. Hasson.

I wish to say that it is a matter of great satisfaction to me to see that we have come down to the present time. I was very much afraid that I was going back to California with the idea that I had only been indulging in reminiscences of successful failures, but now we have got down to date.

We are now discussing a subject that is really of vital importance in electricity to-day. As a consulting engineer I represent a variety of companies in California who desire to transmit power electrically. The aggregate will amount to some 40,000 horse power, distances ranging from ten to forty miles Notwithstanding the fact that Mr. Scott has referred to the successful transmission of power for lighting purposes at San Antonio for twenty-eight miles, the transmission of power electrically long distances in California is a failure. Over a year ago the first contract for a definite transmission of power was closed. I see to-day an unhappy superintendent of a mine up in eastern California, up in the mountains, looking at his burnt-out field coils after this generator has been in operation for less than thirteen days. Although this whole plant is very beautiful upon paper, although it is all logical, the mere fact of the establishment of a small plant for operation in an exposition, as we have here, and saying that all this may be done, does not establish the commercial success of long distance transmission of power. The points that are necessary in this machinery are, first, that it shall from its inception and from its installation operate successfully; the second, that it shall continue to operate. The machinery must be so built that it will not run not only a day or an hour, but it shall run for weeks and months. It must be borne in mind that where this power transmission is necessary is almost invariably in countries where they are distant from railways, where repairs are impossible; and the machinery must be of such a nature, not only in its simplicity of construction but in its lasting qualities, that accidents will be something that is almost impossible to happen to it.

I believe in the transmission of power. I have been the apostle of it for a year in California, but I must definitely establish the fact that as far as California is concerned, as far as the investors, the men who make a success of long distance transmission, bearing in mind that no electric machine has any actual utility, that no transmission machine is of any use, unless it will stand high voltages only—we may overcome the list of defects and arrive at the correct manner of handling them—I wish to say definitely that to the investor in California to-day the successful machine for long distance transmission of power electrically exists only apparently in some special machine in the minds of the inventors and the promoters, or in some beautiful advertisement.

I wish further to state that some four or five months ago I was called upon to decide upon certain plans for the transmission of 3,000 horse power some twenty miles. Most elaborate, most beautiful detailed descriptions of the methods arriving at these results were put before me, but not a single working drawing of any kind was presented by any one of the three companies that were competing for this installation. I wish now and trust that the people who have been associated with the development of this long distance transmission machinery will discuss this question. It must be recognized that these experiments are so extensive that they can only be carried out by companies. I have waited and waited for information, and all that I can arrive at in that way is that one company says that 800 volts is the limit to multiphase generation, and another company says with equal positiveness, we do not hesitate to install 2,500 or 3,000 volts initially. Which is right? How are we to determine until these plants are installed and carefully operated. Again, we have been promised a long while a three-phase transmission in southern California. I understand that it is going out there now under special guard, and I trust that it will be taken care of and that it will arrive safely without any accident happening to it.

Dr. Bell.

My friend Dr. Scott has so well described the characteristics of a typical polyphase system that as regards the general characteristics of it I myself would have very little to say. I would only say that I am very glad that he has referred to the two-phase system as a polyphase system, because it gives us one word instead of two for the motor, and that all which applies to the two phase system applies in varying degrees to all other numbers of phases. The general methods in the apparatus are the same in principle, only differ in such details as inventors have found desirable to introduce, so that all the polyphase systems are capable of doing practically about the same work. The differences, it is only fair to state, are differences less in degree, far less, than the difference between the polyphase system and any other system of power transmission. There are in general three methods which are at present offered and proposed for power transmission: that of the direct current, which Prof. Crocker has been championing before us this morning; that of single phase currents, and that of polyphase currents. Of the first I have only to say that in this country at least it has not been altogether a shining success. The experiments have mostly resulted in failures. I hope that M. Thury will be able to give us a far more encouraging report from the other side of the water. The great difficulty seems to be that which was suggested by Prof. Crocker, that when your current goes up you begin to get into trouble. Voltages which are perfectly practicable on the five horse power machine, or on perhaps a 60 or 70 horse power arc machine, become difficult when you want to transform to say 500 kilowatts or more in single units, and the cases of power transmission are frequent where there is a call, and a very imperative call, for units as large as 1,000 horse power. I am afraid that for these big units we need even more experience than Mr. Hasson has thought necessary for the general problem before we get a successful direct current machine.

Second, we come to alternating currents, and we have to ask ourselves the very pertinent question, Why do we want them? We want them for the reason which has been very well set forth by Mr. Scott, that when we get an alternate current we can do something with it. We can twist it around in almost an infinite variety of ways, and set it to almost any application. Where we are dealing with a direct current, it is a direct current from start to finish, except as we transform it at the cost of more complication and an initial expense into alternate currents. Furthermore, we do not need the direct current for motors nowadays, and that is sufficient reason why we should consider the alternating current as the coming thing in power transmission. So long as the direct current had a grinding monopoly of all the motor service, it was direct current or nothing. To-day that is changed. The single phase system, with which we have all been familiar in lighting for some years, is, as we know now, largely through the experiments of our foreign friends, applicable to motor service as well; not as well, however, I am sorry to say, as the polyphase systems, nor is it as well adapted to the operation of the beautiful rotary transformers which have an essential feature, as Prof. Duncan has suggested, of the coming power transmission by polyphase currents. We know from experience that the single phase rotary transformer is not capable of quite so good a contact and is less desirable in other ways than the polyphase one. As for the single phase motor, such as has been exploited abroad, I can say as a result both of what we have heard from other experiments and from what I know myself from personal experiments, that the single phase motor in its present stage of development can be considered as nothing else than a rather poor polyphase motor. It starts on the polyphase principle every time, and with the objection that the rotary field established is not a circular rotary field, but an elliptical one, consequently less efficient as a rotary field, and giving less efficiency in the motor. When we are not driven to using a phase different motor, if we wish to start a single phase machine we have to use some variety of commutation running out through any synchronized motor, with its well-known limitations, or else into the non-synchronous motor of the type which we have recently been hearing about, which, as I have just stated, is not as good as a good polyphase motor. If you are building an induction motor of any kind, and set out to secure a single phase motor, you will have a most phenomenally good polyphase motor before you are through with the machine.

Then finally we come to the polyphase systems. Essentially they operate on the same principle. We may, however, divide them into two classes, polyphase systems having two wires per phase, that is, having an independent circuit, and polyphase systems having non-independent circuits. In this latter case we get some simplification in the wire. A two phased system with four wires one may fairly call practical. With three wires, combining two of the phases in that way and combining the two phases partially in that way, it is somewhat simpler. The three phase system operated on separate circuits, which would require six wires, I think we are all agreed is prohibited. Operated with combined circuits it requires but three wires, as few, in other words, as were required by any polyphase system. Furthermore, in all of the non-independent circuits, polyphase systems save copper as over the direct current, the simple alternating or the polyphase systems with separate circuits. They save copper in varying degrees, the two phase in about 72 or 73 per cent., the three phase about 25 per cent., and those systems which have more phases as a rule less than either of those mentioned, the saving lessening with the number of phases. We need not concern ourselves with that much, on account of the prohibitive number of wires required to install them, even with composite circuits. We therefore have, as distinguished from the independent circuit system, which is so well exemplified in these diagrams, a second kind of polyphase system with dependent circuits, interlocked circuits, which possess the valuable property of saving up to 25 per cent. of the copper, and also giving less self-induction and capacity on the line then alternating, so that for very long transmissions it saves both in the copper and that intolerable nuisance, line inductance. Line inductance I trust in the future will not be as serious a matter as it is now, or has been in the past, thanks to the suggestion of my friend, Mr. Steinmetz, in his paper yesterday.

As regards the general differences between the independent circuit polyphase and the dependent circuit polyphase system, one can only say that the independent circuit requires at least four wires. The dependent circuit requires at the least three wires. This in the question of installing lights is a comparatively slight difference, because you are going to split circuits anyhow in those cases. In the matter of motors, the three wires are somewhat more convenient than the four. The great objection which has been raised against the polyphase system with dependent circuits such as the two or three phase system with three circuits, is that it does not regulate well, and the principal thing that I wish to put before you is that that criticism is absolutely ill founded, as we know from positive experiments. In the first place, it is quite possible so to arrange a dependent circuit polyphase system that the difference between the different branches of the circuit, even under extreme conditions, will be almost intangible. That too was pointed out by Mr. Steinmetz in his paper yesterday. The means of doing this are not always simple, and it is therefore well to state as a result of positive experiments that without any complicated means of compensation whatever it is possible to obtain closely concordant voltages in all branches of a polyphase system, independent of their operations in the old branches. If you cut off all the branches but one you will obtain a perceptible variation. If you cut off one of the three branches of a three phased system you will obtain a variation which is scarcely visible to the eye.

With respect to the motors on the polyphase systems, I think we can readily appreciate from what Dr. Duncan has said that between 2, 3, 4 or M. phase motors there is not any very wide difference in principle, nor is there any very wide difference, or any perceptible difference one may say, in their operation on independent circuits or dependent circuits. The whole point of the matter is this, that if you are going to obtain equal results, whatever the number of phases, you must practically have a motor of about equal classification. In other words, for equally good results, the four phase motor would have to be just about the same sort of a machine as regards complication, binding, etc., as the three phase, and the two phase would have to be just about as complicated as the three phase. They would have to be practically nearly alike if you are going to get precisely the same results, but when these motors are properly designed I do not hesitate to say as the result of experience that they are decidedly superior to any direct current machine, and that is one of the strong reasons for using the polyphase systems instead of two currents. In the first place these machines have no commutators, and in the second place it is almost impossible to burn them out. I have been experimenting with motors of this type for a long time and I never yet succeeded, even under the strain of the toughest kind of experimentation in burning out a single machine in any way whatever, and I do not think that is a record that could be well made with any sort of direct current motor. If they are overloaded, they stop and will not burn out for a pretty long period. Under any ordinary circumstances they simply stand up to business without any commutation, without any complicated connections. They start quite well, as well as any ordinary direct current motor, and I beg leave to correct Dr. Duncan in his statement that eight or ten times the running current is needed to get a good start. The motors in respect to currents taken start just about as a shunt motor starts. Furthermore, the speed of these motors can be varied. It is non-synchronous, and when it is non-synchronous I do not mean to say that it is non-synchronous in the sense that a single phase motor is, but that it is non-synchronous in the sense that a series motor is. It is possible to run a polyphase motor at a widely varying range of speed, keeping up practically constant talk (?). The range of speed is practically varying from one-tenth speed up to full speed, keeping constant talk all the time. This, I think, escapes one of the objections which have been raised against polyphase motors.

---

* Discussion held at the International Electrical Congress, Chicago.

One further thing I would say and then I am through. I want to defend the polyphase machine against the accusation of the lagging current, against the accusation that it will queer the regulation of every dynamo that the mind of man has found means to invent. It is simply not so. If a polyphase motor gives a big lagging current at or anywhere near full loaded, it is proof conclusive that the machine has been badly designed, that the man who made it did not know how to utilize his magnetic circuit intelligently. There is no necessity of having more than 10 per cent. lagging current in any polyphase motor, and, indeed, one that shows much more than this I should consider badly designed. As an example of what is perfectly feasible and practicable in the way of reducing lagging currents, I would say that I have experimented with motors of sizes up to twenty horse power, where the crossing the angle of lagging, I call it 5 here, is from 85 to 95 per cent. I only recently experimented with a five horse power motor, and I think this ought to satisfactorily dispose, once for all, of the statement that the polyphase motors require an enormous lagging current. And more than this, suppose the current does lag 5, 10 or 15 per cent. It is perfectly feasible to compensate the dynamo by very simple means against the lagging current, even where there is a considerable difference in phases. I recently tried such a compensating device of an exceedingly simple and practical description, with the result of holding the voltage of the dynamo practically constant from no load up to full load when the load itself was of the worst possible inductive character. The machine itself was a little experimental affair, one of 30 kilowatts, constructed out of an old alternator frame, it being the worst machine which I could pick for the purpose and selected intentionally, but the machine required two and one-quarter times the excited current at the full load that it did at no load. In other words, it is possible to automatically regulate the voltage of a polyphase generator in spite of even a severe lag in the line due to the operation of motors, and finally this lag due to the operation of motors becomes evanescent when the motor is properly designed. I am satisfied if I have been able to defend the polyphase motor against this false accusation, and the polyphase systems, whatever the number of phases, against the accusations of insufficient regulation.

Mr. Stillwell.

I have not come here with any paper, and have no speech prepared; in fact, I just arrived and have only listened to the remarks of the last two speakers, so that I should be afraid to go into any elaborate or detailed discussion of the polyphase systems as I see them for fear that I might be taking your time in simply repeating what has already been said.

I would like to call your attention, however, to the exhibit which has been described by Mr. Scott. I believe that that exhibit marks an advance in polyphase work, and I know that it will enable those who examine it to ascertain for themselves what is practicable by this system on a scale that has not hitherto been attempted. In preparing this exhibit of the Westinghouse Company we have not shown small machines. It is no exhibit of tops or models or drawings. We have simply shown there what we believe to be the best development of the polyphase system as we can build it, and look at it. Now, what have we accomplished in that system? We have one generator and one transmission circuit. At the receiving end of the line we have direct current and alternating current at various potentials, performing every kind of work to which electricity is applicable. I think that it is sufficient to show that the system is well worthy of careful examination and study. I have no doubt that further advances will be made, but we have here machines which mechanically are very excellent and electrically are capable of a very good performance. I think it would be interesting, if time permitted, to begin at the receiving end of the station and work back to the generating end from each kind of work that we perform, that is, from the incandescent lighting, how many lights and how many applications we have on the way. If you will work that out for yourselves you will find that the efficiency is in all cases very high, and that in all except as regards arc lighting we have introduced the minimum number of machines and of applications of energy.

We are aiming, of course, not at a partial solution of the problem of transmission, but at a broad and general solution, the door to which was opened by the invention of the polyphase system. There have been very many partial solutions, and we have as the result of such the direct current systems of limited applicability and the single phase systems. We have here a system which performs all kinds of service over a single transmission wire and from a single generator. Of course in a large station we would use several generators and as many circuits as might be demanded by the amount of power needed.

Now, I have one thing to say in regard to the evolution of this business. There are concerns in it—manufacturers, and those who propose to buy, users, and lately we have an intermediate class, consulting engineers, as yet less numerous on this side of the water than they are on the other. We are very glad to welcome them in their work, as they certainly have their place in protecting the interests of the customer, and also in explaining to the customer what the manufacturer is trying to sell him, to assist the manufacturer in convincing the customer that he is warranted in putting in his share of the necessary investment to carry the thing through.

Now, we have in this plant attempted to do this. We have spent a large amount of money in putting in a very large and expensive exhibit of our machine, and will be glad to exhibit it to those who may be interested and to whom we may properly extend that courtesy to make such tests as will, we think, satisfy them as to the performance of the apparatus. We have not attempted to show the insulation of our circuits for long distance transmission, although we might have run a circuit around the city of Chicago and come back to the switchboard, and carried our potential at 10,000 volts and operated it. That has been demonstrated in Germany over a longer distance and over a higher potential than our very high potentials are in commercial and successful operation in this country. Now, it seems to me that the consulting engineer is the man who must put two and two together and solve this problem for us. He is the man to stand up to the customer and to the world and say, this thing is practicable and it is a success. It is not for the manufacturer to pay for the apparatus and install it and operate it and guarantee dividends, as has sometimes been proposed.

The Chairman—I see a gentleman here who is familiar with long distance transmission, Mr. Freke of Munich, who is well known in connection with the subject of distant transmission. I will ask him to make a few remarks on the subject.

Mr. Freke.

I have heard here that some have recommended to you the polyphase and some the direct current. I should like to say that no system is the best. I think the direct current system is a very good one, the polyphase current system is a very good one, and the single phase current system is a very good one for the transmission of power. For the purpose of demonstration I should like to give you some instances from the other side of the water. I will not speak of Genoa, as I suppose M. Thury will tell you himself of the transmission of power there, where they are operating with 6,000 volts and a perfect system of dynamos.

We had in Germany two years ago a long transmission of 100 miles by circuit up to 30,000 volts, but people seem to be incredulous when I tell them of it. They said, well, it is very good for an experiment, but we should like to see some line working for a long time. Well, gentlemen, I can tell you I was at the works of Oerlikon two or three months ago, and I saw the transmission of power working, which had been in operation for, I suppose, 15 months, of 13,000 volts. It was a three phase current transmission on the same system as the transmission from Lauffen to Frankfort, the work being perfectly good all the time. Their motor was a 300 horse power motor constructed in the same manner as the generator.

Now, of the single phase system I said it was also good. I saw in Switzerland a 100 horse power transmission. I will tell you it was not a self starting 100 horse power motor, but had a very good device. It was for lighting a mill, and there is a small single phase motor of 2 horse power to put in motion the big one. As soon as the big one was in place the generator was coupled together and worked well as a motor. Now, this little single phase motor is now constructed by Messrs. Brown, Boveri & Co., the well-known builders, up to, I suppose, 10 horse power, as I have seen motors in perfect condition. They are put in action a two phase motor, and as soon as the motor is running and synchronized with a generator it is put on the main circuit as a single phase motor, and runs nearer synchronizing, and does not stop at an overloading of 50 to 100 per cent. These motors we have in use in a little town near Munich, and I can say that of the 15 motors they have there there is not one that has given any trouble and the people that use them are all very content with the work they are doing.

I might conclude by saying what I did before, that no system is the best. I do not think so. One system may be the best for some special work, but there is no only one best system.

Prof. Thompson.

May I first speak for M. Thury? He has asked me to place before you the following points: There is at Geneva a transmission of power at a constant potential of 1,200 volts, with a simple continuous current, the motors being shunt worked. There is another at Stanzerhorn working with a generator of 150 horse power at 1,500 volts and about 70 amperes. This works three motors each of about 60 horse power nominally. There is another case of distribution with continuous current, but with excitation with the generating plant, consisting of dynamos in series.

This is from Biberist to Rondchatel, a distance of 29 kilometers, about 20 miles. Two generators of 200 horse power each, current of 40 amperes, 3,500 volts, tried up to 4,500. A fourth installation is at Genoa in Italy. There is a continuous current having a constant flow of 45 amperes, eight dynamos as generators, all joined in series, each nominally about 1,000 volts, each about 60 horse power, these eight not running quite at 1,000 volts each, the line being at 6,000 volts in ordinary work, because if you keep the current constant the volts will vary according to the demand at the other end. There are two circuits feeding motors, varying from 5 horse power to 100 horse power, and from 100 volts to 2,000 volts, and these are all examples of practical installations for which M. Thury makes himself responsible.

Now, to speak for myself, first of all let me deal with the continuous current problem. Let me point out that for other purposes than the mere furnishing of arc lights, machines have been constructed, continuous current machines, to work out high voltages. In London Mr. Essen has designed various dynamos working at from 1,000 to 2,000 volts, using commutators of the ordinary kind, but when I say commutators of the ordinary kind I mean that they were the ordinary straight bars of hard copper or something of that kind, but they were specially insulated and they had to take special precautions against lapping over. In one machine they adopted the plan of wiping out any ordinary spark that might occur upon the commutator by imbedding the whole thing in a mass of asbestos which wiped out any spark which might be formed under the brush. It was a rough and ready device, but it "got there."

Again, in Germany, Mr. Lavier has carried out many examples of transmission of power with continuous currents at 1,000 volts. The difficulty does not seem to arise so much from the sparking of the commutator as from the inherent difficulty which is met with everywhere when you begin to apply with continuous currents any high voltage, namely, that of electrolysis of your insulating surfaces or insulating materials that may occur in any place exposed to moisture. We know that electrically caused fires from leaks in the mains more often occur with the continuous current than with the alternate, no doubt because the continuous current draws up electrolysis in the moisture and the alternating current does not do so, at least not in the same way.

May I point out that in the old-fashioned university town of Oxford, England—I must not claim for it that it is a long distance transmission of power but it is a transmission of power by continuous currents at high voltage. The town is supplied from a lighting station something like a mile and a third, over a mile and a quarter, and the current is brought in at something over 1,000 volts, while in the city of Oxford this current is transformed by continuous current transformers, that is to say, from motor dynamos, to the low pressure of 100 volts, and conveyed into the neighborhood all around, from house to house, and that installation has been going on now for many months and goes without any trouble. These rotating and continuous current transformers have a very high efficiency, and so far as my information goes there is no trouble from the sparking at the commutators.

Now, let us go to the alternate current work. I would invite every electrical engineer interested in this subject to study very carefully the installation at Rome, which is fed by the power of the waterfall 14 miles away, where there is a station, erected by the firm of Ganz of Buda-Pesth, where the water from the waterfall falls down turbines and drives alternate current machines which supply current at from 5,000 to 6,000 volts, carried across 14 miles over the Campagna until it arrives outside the gates of the city of Rome, where there is a transformer station which brings it down from 5,000 or 6,000 volts to something over 1,000 volts, from which again lines go into the city to be transformed down to 100 volts, being the low pressure for the work.

I have listened with great pleasure to the discussion originated by Dr. Duncan and carried on so ably by the engineers of the Westinghouse Company upon the question of the polyphase transmission. I have studied that polyphase transmission at Frankfort, where we had it in some 8 or 10 different systems, all rivals of one another, from the various houses of Germany. We had the great houses of Schuckert, Siemens & Halske, Lehmeyer and several others, each of them showing their own way of carrying out a polyphase system, and we could compare the one with the other, and it was very interesting to see how they all had solved in their own way that problem to which so much attention has been drawn here, namely, making a rotary transformer transform a continuous current into a simple alternate current. No doubt their rotary transformers will be of service in the industry, but I imagine they will be of service rather in particular instances than in any kind of general way. Let me entirely endorse the remarks of Mr. Freke, that there is no best system, that each system is the best for its own purpose. What would you think of an engineer who could stand on the platform here and say that he had invented, or that any man alive had invented, the best steam engine, and that there was no other? You would want to know what that steam engine was best for, whether it was suited for a mill or a threshing machine or a large factory or a steamboat or a locomotive. There is no best steam engine. There is no best dynamo, and there is no best motor, and there is no best system. They are all right. They are all best.

Well, then, what is the polyphase system composed of, and what is the simple alternate system composed of? I am not going to prophesy. I do not know what ten years may bring forth, but I will give you my own personal opinion as to how the thing stands at present. I do not love the complication of three phase transformers, and three phase switchboards, and three phase motors. I love the three phase or the two phase alternate current dynamo and motor. They are very beautiful. They can do a great many things with them, but I do not love the complications of switchboards and transformers. I do not love such a complication as that. It is very beautiful, it is extremely fine, it is costing a mint of money, but I do not love it because of its unnecessary complications. For all distribution systems—distribution, I say, not transmission systems—where you have not only to transmit but to distribute to this and that and the other consumer, I believe you will abandon all the complications of polyphase work, and that you will return to simple alternate current methods, and I believe you will find that the bugbears that have been raised, the ghosts that have been put up to frighten you off the simple alternate current system, will disappear in practical work, and that the motors can be made as highly efficient and as comfortable with simple alternate currents as with any polyphase system. As I said before, I do not desire to prophesy, but I venture to predict, not in the way of prophecy, but simply giving you my personal opinion, that the simple alternate current work will be the thing which ten years hence will be found to be effective for all long distance transmission where you want to distribute at the consumer's end.

One final word in conclusion. We in England are trying to get our stations—I am speaking mainly of lighting stations—whether they work by high voltage or low, down to the utmost simplicity of engineering. We shall have one type of engine suitable for its purpose, not half a dozen different scratch lots in the same station, and one type of generator. We have one simple bar, or at most three, if you are working on a three wire distribution. Everything is tending in the direction of simplicity, and the results are excellent.

If I had come over here expecting to go back to England and say the apparatus you are working with has got down to such a beautiful stage of simplicity in the States that you will have to give up everything you have got in the old country and adopt the polyphase system. I should think that I would have been very effectively disillusioned, but the complications of those two diagrams which I see before me, although they represent a most enormous amount of research, of invention, of instruction and of capital fearlessly placed at the disposal of the inventors, are sufficient evidence to my mind of the correctness of my views. I admire what has been done, but while admiring it I cannot help thinking that there is something simpler which will be the successful machine of the future.

Prof. Thompson's remarks were greeted with great applause, and at the conclusion the chairman introduced Prof. George Forbes, of London, who addressed the section as follows:

Prof. Forbes.

Nothing, Mr. Chairman and gentlemen, could give me greater pleasure than to be told that I am to be limited to five minutes. I have half an hour ago landed from the cars and I have only just been able to manage to come into the tail end of your discussion. I had expected to arrive early this morning and to be here on time, and I traveled in order to be present at this discussion. I labor under the disadvantage of not having heard the papers read, of not knowing what the subject under discussion is, of only having heard the last part of Prof. Thompson's remarks, and being suddenly called upon to address you on the subject under discussion. I know that the subject under discussion is the subject which has been continually occupying my mind for many years back, for which I have been making journeys to the United States year after year and to every part of Europe where I thought work in this direction was being done. It is a work which during the last year and a half has been the incessant occupant of my mind, and not one-quarter of my time, awake or asleep, has been taken away from this subject, and it is impossible to compress into five minutes all the things I would wish to say to you on this subject. Briefly let me take up the points which Prof. Thompson was alluding to, and say a few words on some of them.

The first question that arises in this matter is the relative importance of direct and alternating currents. Prof. Thompson has wisely said with regard to the different systems that each has its own sphere of action. He is perfectly right, and everybody who has gone thoroughly into the question will agree with him. The grandest work in connection with the use of the continuous current for transmission to distances is that which I have seen at Genoa. They have done a splendid work in putting that down, working at high voltage. They have worked even up to 6,000 or 8,000 volts. They are now doing other work in the same direction. The continuous current can be used for transmission to a distance, and in many ways it is extremely convenient, but it has none of the beauty, none of the diverse applications of the alternating current. The trouble which exists in the commutator is a very serious one, and I will not dilate upon it further as it has often been spoken of. The trouble in insulating the armature is a very serious one, largely because in continuous current machines the armature must be the revolving part. In the alternating current we may have the armature as the fixed part. In that case the armature is just as easy to insulate as the high tension side of a transformer. You may put oil into it if you wish to carry off the heat, but if you trust in any way, and it is dangerous to trust far, to its extra insulating properties, it is perfectly unmoved. You may place the wires so that they are not acted upon by the mechanical action of the magnetic field. Prof. Thompson has said to connect the generators in series and you get your best insulation. At the receiving end it is necessary to do the same. You cannot have a 5,000 or 10,000 horse power motor in every workshop, and you must put them in series and the complications are manifold. I will not go further into this question. I have stated the general points and I will now devote the remaining two minutes to another subject.

The great charm and beauty of the alternating current lie in the flexibility introduced by means of the transformers. It is impossible to overrate the advantages of the transformer. A continuous current introducing rotating transformers has no comparison with the simplicity and the practicability of the alternating current transformer. I was pleased to hear Prof. Thompson speak about the single phase. The single phase is a great thing at present and has great possibilities in the future. I have had a very long experience of synchronizing alternating machines used as motors, and I have the very highest opinion of it, but they are only applicable in such cases where the motive power is required constantly, day and night, from week's end to week's end. For electrical construction works the synchronous motor is admirably adapted, and also to motor mills, but for all appliances where we have to start, stop and reverse our motors, it is practically out of the question to put in the synchronizing system. I have watched in the workshops of the greatest practical electricians in the world the progress that they have been making in the last three or four years in the evolving of an alternating current motor which shall stop and reverse with facility. Until quite lately there were none of those which were thoroughly suitable and applicable to ordinary lighting circuits. Now, however, we are able to use, as Prof. Thompson has said, a polyphase system for starting the motor, and use it synchronously afterwards, or nearly synchronously. This is a very great advance and I personally have great hopes that the single phase is going to play a very important part in the future.

On the subject of the best means to adopt, my tongue has been considerably tied, and with regard to the relative advantages of the three phase and two phase systems, on a late occasion, at the Electrical Light Convention at St. Louis, when I was asked to speak, for reasons which were readily appreciated, I was not able to speak on that subject. Those reasons no longer exist. I beg to say that as far as I have studied the two, and I have given a great deal of personal and practical study to it, my opinion is that they are both very good, both very excellent, that the three phase is an attractive one from its theoretical beauty, but in practical execution the two phase is better. The reason why I have a dislike to using the three phase is, first, the complications caused by having three conductors, all interconnected. This introduces troubles in locating the circuit. It introduces troubles in testing, and it introduces troubles in correcting a fault which has arisen. I can imagine the perplexity of an ordinary central station attendant when he is told that there is a fault in the line, in his endeavors to find it; if it is a three wire system where that fault is, it increases the labor enormously, and with two phase the wires may be interconnected or they may be separated. I prefer to have a two phase system with separate independent circuits, and then they are more easily managed, and more easily regulated. Moreover, when the three circuits are interconnected each one has an influence on the other. If you overload one circuit and underload another circuit, the underloaded circuit has a pressure enormously higher than the overloaded circuit. That is a fact which is generally known. It is not generally known that if you have three circuits, A, B and C, on the three phase system, if A is overloaded and B and C are not loaded, then B may be a higher voltage than A, but C has a higher voltage than either of them. That is a fact that is not generally known, and has to be known to be appreciated. It is a very serious drawback to the use of the three phase system. For lighting purposes it condemns it. I have advised the officers of the Cataract Construction Company to reject the three phase and to build their first dynamos with two phases,

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Electrical Literature. The science of electricity, in spite of its youthfulness in comparison with most of the other branches of science, has been a subject for study by some of the most notable scientific men in the world, and possesses a considerable amount of literature in regard to pure theory and mathematical deductions, as well as treatises of a popular and historical character, but one branch of this subject, and the most important one, viz., the practical text-book, is yet almost entirely unknown in this class of literature.

The most prominent books treating of electrical subjects which we have to-day are almost purely theoretical, deal with machines already built and the mathematical demonstrations of general electrical laws. The other books are chiefly descriptive in character, and not infrequently contain much that is absolutely useless, including minute details of dynamos and electrical apparatus which pertain to ancient history and are practically obsolete in present times.

While these books collectively contain most all of the information extant in the electrical field, this information is so scattered, and is so often buried beneath a mass of complex formulæ, that it remains almost inaccessible to the grasp of the average beginner in the study of electricity.

In every other branch of mechanical science there are to be found text-books which give in concrete form practical data and rules for the guidance of practical workers, and while these books are in the line of memoranda and note books, and are not to be considered as substitutes for the more complete works from which they are compiled, they are nevertheless the most useful volumes in the library of the practical electrician.

Take for example the subject of dynamo or motor designing, with which the consulting engineer is often confronted, and assume any particular conditions of size, weight, speed, etc. A few men in the manufacturing business, and others who have become familiar with the subject through experience, are the only ones capable of undertaking this work, for the reason that no one outside of the few mentioned are in the possession of necessary data.

Such information, which is the most essential kind, is not to be found outside the private notebooks of a few men, and it is in just this respect that the literature of electricity is found wanting. A text-book could be readily compiled which would enable the student to design an efficient dynamo according to the conditions implied without even the use of higher mathematics, and it is doubtful if the calculus enters into the calculations of the most successful designers of dynamo machines. It is just as well to recognize the fact that there are too many factors entering into this problem to make its solution a definite one. In almost any case we have a variety of conditions which may be dealt with according to the special requirements, and which do not admit of any single absolute solution. Beginning with the armature, we have the diameter, speed, winding, section of core and degree of saturation, besides a number of other conditions, all of which may vary, and it is only by assuming values for certain of these factors that a general solution is possible. The problem, therefore, contains five or six independent variables which the most astute mathematician would at once pronounce incapable of solution.

We find then that in this branch of work the practical formulæ are largely empirical, and are based upon the result of experience. For this reason a handbook dealing with the subject of electrical machine design in the same manner that the numerous mechanical and civil engineers' handbooks treat their respective branches, would be not only a welcome addition to the literature of electricity, but a much-needed help to the practical workers in the science.

……o……

The Situation of the Sham Trust. Boston people who are not insiders, and some New York people, are wondering at the apparent strength of General Electric stock. It looks to ELECTRICITY as if the "apparent strength" of an 8 per cent. stock still selling below 50 requires little comment.

Readers of this paper have been kept well posted from week to week on General Electric news. When there is news we have it, and have it straight.

But it should be remembered that the news of a battle is only news when the fight is going on or immediately after. The doings of the defeated and surrendered army are of slight interest. We have, therefore, paid little attention of late to the battered and defeated General Electric Company. Of news there has been none, and it is yet a little too early to write history.

Boston is still thoroughly imbued with the idea that all the troubles of the General Company are an inheritance from the Edison General Company, that the condition of the latter company was misrepresented at the time of the consolidation, and that an immense floating debt was hidden. Any one who knows anything whatever of the inside workings of the Edison Company knows that this was an impossibility. Either Mr. C. A. Coffin is a blockhead (which he is not) or else he knew exactly where the Edison Company stood. The information was within his reach.

The burden of misrepresentation is on the shoulders of no other man than Charles Ali Baba Coffin. He came to New York with the endorsement of Mr. F. L. Ames and other Boston capitalists of standing and high reputation, and it was this endorsement, rather than any special knowledge of the man himself, that Drexel, Morgan & Company accepted. They believed in him because they knew the character of his friends. It is now known, and susceptible of proof, that for once the house of Drexel, Morgan & Company were humbugged. It has been until now an unwritten fact (and it is a fact) that the late F. L. Ames had changed his opinion of Mr. Coffin absolutely, and that he was working in entire harmony with the Drexel-Morgan interest to rid the company of Coffin and his fellow gamblers who had wrecked the concern. With Mr. Ames gone, this result may be longer postponed.

The chief interest in the situation now centres in the question, Who is in control? This question is often asked, but has not yet been authoritatively answered, and for good reasons. Neither faction is to-day in full control, and when the returns are all in Electricity will be the first to announce the result. We feel at liberty to say that Mr. J. Pierpont Morgan is intensely interested in the stock, which was strongly recommended by his house as a purchase at par; and it is well known that Mr. Morgan's plans are not easily learned in Wall Street. We look for a radical change in personnel and in policy within a few weeks.

The financial condition of the company does not need to be discussed. Receivership papers were drawn up some five weeks ago, but the necessity for filing them has not yet arisen.

As to the withdrawal of the Fort Wayne Company, cool-headed men will suspend judgment. It is either *bona fide* or it is not. "There is an uncertainty in all human affairs," and two old campaigners like Mr. McDonald and Mr. Coffin need to be watched closely. Rumor has it that the Fort Wayne Company will be called the Western General Electric Company.

When the cat jumps Electricity will get a snap shot, and will duly record his landing place.

······o······

Our Foreign Critics. Considerable has been said pro and con in regard to the results of the International Electrical Congress at Chicago, and while many of our contemporaries appear satisfied with the work transacted by that body, a few have criticised it without stint.

In regard to the work of the chamber of delegates there can be but little to criticise, as the views of the various representatives had previously been thoroughly discussed by them in the electrical press, long before the date of the congress, and for this reason nothing remained to be done during the limited session of the congress beyond ratifying the decisions which were at the time of the meetings almost foregone conclusions.

The criticism in regard to the discussions of papers, while in some respects justified, is also carried beyond the limit of reason. One of the critics laments the fact that "nothing new was disclosed"; and lamentable as this may be, it is entirely conceivable that even an International Electrical Congress may be insufficient as an incentive to new and brilliant discoveries. The criticisms on the character of the discussions, however, we feel are not unwarranted, but the failure in this respect cannot properly be charged to the congress as a body. Ample time was given to the authors of the papers to forward their manuscript and have it put in type before the meetings, but with a very few exceptions this notice was disregarded, and almost all of the papers were heard for the first time at the meetings, giving no opportunity for the members to study the subjects discussed or to prepare any careful consideration of them. Whatever is said upon this subject, it must be apparent that the failure in preparing advance copies of these papers, without which intelligent discussion was impossible, rests solely with their authors in not complying with the regulations laid down by the congress, which called for the papers in ample time for printing and distributing in advance.

······o······

Is a man like Mr. C. A. Coffin, whose chief interest in life is stock gambling, who has encouraged all his intimate friends among his employees to follow the same bent, going so far at times as to carry their margins for them, the proper man to be at the head of a large manufacturing enterprise?

······o······

Cleveland bankers will do well to consult—well, Mr. J. Pierpont Morgan, for instance, before they turn the money of their depositors over to Mr. Coffin to assist him in prolonging what has been from the first a disgraceful confidence game.

······o······

A gentleman of high standing in the trade said to us last week that Mr. Coffin made the mistake of his life in not getting control of Electricity a year ago. Not so. He showed exquisite judgment in not making any such attempt.

······o······

When the General Electric gambler employees get so low in pocket that they can't patronize a legitimate broker, they can still lose their fives and tens in the bucket shop which occupies a prominent place on the ground floor of the building at 44 Broad street.

······o······

There is renewed gossip of a consolidation of Westinghouse and General Electric interests. It is all nonsense. Any such consolidation is an absolute impossibility.

······o······

The men who are claiming that the Edison lamp patent runs till 1897 will know more in sixty days.

······o······

It will be evident to those who read the communication on the "Fall of Babylon" in another column, that "Recapitulator" has been a close reader of Electricity.

······o······

By a strange coincidence Mr. C. A. Coffin and Mr. B. E. Greene were both registered at the Hollender House, Cleveland, on Friday last.

······o······

"I'll mine beneath their deepest schemes and blow them to the moon."

An electric street railway was built under somewhat unusual circumstances at the little Dutch town of Hanover, in Pennsylvania. A fair was to be held there during the third week of September. The residents were anxious to have the road in operation during the fair. The work not progressing fast enough for their satisfaction, they volunteered to help build the line gratuitously, and merchants, mechanics and professional men took up the pick and worked in turn on the street. A procession of about 100 men from a neighboring village entered the town one day, headed by a brass band. The men carried shovels and picks on their shoulders, and at the command of their leader set to work and made the dirt fly for several hours, during which time the band discoursed lively airs. When nightfall arrived the men formed into a solid phalanx, gave three cheers for the electric road, shouldered their tools and marched to their homes.

CORRESPONDENCE.

The Chicago District Office is Mr. Sunny's Private Snap.

To the Editor of Electricity.

My attention has been called to an article in Electricity of Sept. 6 in which you seem to express surprise "that Mr. B. E. Sunny, general manager of the Chicago office of the General Electric Company, should be called to New York to explain how the final balance sheet of his office should show a net loss of a quarter of a million dollars."

Allow me to say that "there are stranger things in this world than are dreamt of in thy philosophy, Horatio," but the strangest of them all is the management of the General Electric Company in this so-called Western District. To a business man it is surprising, patterned as it seems to be after the manner of politicians, who on the eve of a general election, to perpetuate their power, attempt to blind the eyes of the people by a so-called policy of retrenchment and reform. Permit me to give you a few facts to assist you in solving the problem.

Under Mr. Sunny's management the sales department of the Chicago office alone, aside from the large clerical force engaged, is divided into seven departments—railroad, central station, isolated, supply, meter, motor and mining—at the head of each a high salaried manager, particular cronies of his, educated in his peculiar methods of doing business. The several departments employ all told from 25 to 30 salesmen, or a manager to every four agents. The late "close the barn door after the horse is stolen policy" of Mr. B. E. Sunny is as ridiculous as any of his previous acts, discharging as he has many poor paid employees through whose labors the business has grown to its present large proportions, but still retaining all his high salaried managers, his particular friends. Is it a wonder that you or any business man would express surprise? Is there any business, however prosperous, that would not fall behind under such a policy? With such a showing the many stockholders cannot but look anxiously for the return of the next "dividend declaring day." Enough at present. If you wish, I may at some future time throw a little more light on the "ways that are dark and peculiar" in the Chicago office of the General Electric Company. Yours,

Chicago, Sept. 15, 1893. Stockholder.

THE FALL OF BABYLON.

A Recapitulation.

Below is given a summary of a few of the impartial items on the way that the Only Electric Company down in Lynn carry on their business, previously published in the popular electrical journal, Electricity.

How any company who depend on the commercial world for their livelihood could expect to exist when they have treated the "outs," as they term them, as they have, would be hard to answer.

The games of deception played and the fairy tales told by the company which formed the nucleus of the whole nefarious conspiracy will remain on history's pages as a "horrible example," as one of their engineers termed the direct current plans submitted to the Niagara Consolidated Company before they got an inkling of what some other company was doing.

Their contribution of $1,000 to the New York Press Club is where part of their next January dividend has gone.

Said a large contractor: "The days and doings of such a Trust are numbered." And he had cause to. Having signed a $200,000 contract, he was tendered in payment a check discounted to the tune of $12,000. When he insisted, they tried all the bluff games they knew, but the contractor was firm and was finally paid. Any business firm who can trade with such a deceiving company must be sorely in want.

Then came the Detroit episode. Detroit wanted municipal lighting by the vote of its people. The Only Company did not want that they should. At a Common Council meeting the mayor of the city produced $200 in bills, the paltry sum which had been given to one of the aldermen as a bribe. It is said that they were going to spend $25,000 in this way. Here's where the useless expenses count up.

How any city can negotiate with a company having such low, sneaking methods of procuring business is hard for one to see clearly.

While the Only Company have some smart engineers down in Lynn, they are not over ingenious or of the inventive nature, as their line of production shows.

They wait for the sun-Brown-ed engineer from Switzerland to design their four-pole generator, and a Western-house for its alternator, direct copy. But they are afraid that this Western-house will have something new, so they send one of their draughtsmen down there to enter their employ for the sole purpose of stealing all he can that is new and send it to the New York office. But this Western-house knew a thing or two, and while a little late, they had the whole gang of thieves and bulldozers arrested. True bills were found against them, and convicting letters were shown with their signature on them, but the jury disagreed. This shows that at least there was some ground for the charges, and that some jurymen could not be bribed, possibly.

From the lawsuits that they carry on, one is not surprised that they had to have another company formed to supply them with funds to pay debts and carry on their bluff games. Just what a share in the third company signifies it is hard to tell.

They try to shut up all competing lamp factories, but only encourage the Yankee inventive powers by so doing.

They make the flimsy misrepresentation that they own all the patent rights on the under-running trolley, which is really more comical than serious.

The Joliet Prison affair shows bribery and rottenness somewhere. The Illinois Legislature having appropriated $200,000 for an isolated plant, advertised for bids in the town paper, with a circulation of several thousand, more or less, so every engineering company could see it, and a Chicago weekly.

The plans and specifications submitted to the different bidders all bore the stamp of the Only Company, and were so worded that only their apparatus would answer all the specifications. Boilers were drawn in the plans which could only be furnished by one manufacturer, who of course stood in with the Only Company.

Stock of such a company has been a regular Wall Street football. When stock whose par value is $100 sells down to less than 50, and paying 8 per cent., which is of course at the present price more than 16 per cent. on the amount invested, is a drug on the market, there must be something rotten in Denmark.

Their latest known low-lived trick at which they have been caught is the stealing of signs from the exhibit of another Western concern's exhibit at the World's Fair.

It seems to be against their nature to conduct their business on an honorable basis, and the sooner they drop out of the commercial world the better it will be for all concerned.

RECAPITULATOR.

Bids Wanted.

Bids will be received up to October 2 next for apparatus for an electric light plant at the State Asylum at Wernersville, Pa. Specifications, etc., may be had of Mr. R. Meckle & Co., Drexel Building, Philadelphia.

W. A. Drysdale, 20 Hale Building, Philadelphia, will furnish specifications, etc., for a plant at the Norristown, Pa., Asylum. Bids will be received until October 25.

Iron for Transformers.

BY PROF. J. A. EWING, F. R. S.*

In selecting iron for use in the core of a transformer, the first consideration is smallness of hysteresis losses; high permeability is comparatively a secondary desideratum. These two good qualities do not necessarily go together; the curve of the B–H cycle may have a relatively easy slope, and yet inclose a relatively small area. In actual tests the author has noticed that the order of merit in a set of samples is not always the same if permeability be made the criterion as it is if smallness of hysteresis losses be the criterion.

Notwithstanding the obvious and well recognized importance of small hysteresis losses in transformer iron, the metal that is actually used is often of a very poor quality in this respect. The author has been much struck by this in the course of a recent experimental inquiry in which ten or a dozen specimens of iron were examined, most of which were supplied either as transformer iron or as specially pure metal prepared for the purpose of the experiment. In only one case were the hysteresis losses as low as they had been found to be in some wire which the author tested in 1881, in the laboratory in the University of Tokio, and in most cases the losses were much greater. In the Japanese tests which were made before the days of alternate-current engineering, when the word hysteresis was to be found nowhere but in the Greek Dictionary, wires were taken at random from the stock which the laboratory chanced to furnish. Two of them were about equally good; one of them was probably a piece of native iron, and the other was wire sent by an American manufacturer to an exhibition in Japan. Since then many observers have made tests, and, obtaining decidedly inferior results, have not unnaturally been led to express themselves in terms of politely veiled skepticism about the Japanese figures. It is therefore interesting to notice that one sample among those most recently tested by the author has given results which are substantially on a par with those given by the Japanese wires. Under strong magnetization it is not quite so good, but when the magnetization is moderate or weak there is practically no difference. The sample in question was thin sheet iron, used by a well-known English firm in the building of their transformers. But the corroboration of the old figures, interesting as it is, only serves to emphasize the contrast between the good and the bad. Other iron, also used by eminent makers of transformers, and also, like the last, carefully annealed before testing, turned out so markedly inferior that the author does not care to indicate the sources of his specimens by any more particular description. And the case was even worse with some iron supplied as specially soft and pure.

The following figures may be taken as representative. They give the value of $\int$ HdI, or the hysteresis loss incurred in a complete cycle of magnetic reversal, for various values of the magnetic induction B which is reversed. Column 1 states the results of one of the old Japanese tests, column 2 refers to the good sheet iron mentioned above, and column 3 refers to another specimen of transformer metal, where it will be seen the losses are about half as great again as in the other. Column 4, where the losses are much greater still, relates to a test of some wire which was furnished as a specimen of particularly fine Swedish charcoal iron.

TABLE OF HYSTERESIS LOSSES.

Values of $\int$ HdI.

B.	1.	2.	3.	4.
2000	400	420	600	1100
3000	780	800	1150	2150
4000	1200	1260	1780	3300
5000	1680	1770	2640	4700
6000	2300	2370	3360	6200
7000	2800	3150	4300	7800
8000	3430	3940	5300	9500
9000	4160	4800	6380	11400
10000	4920	5730	7520	13400
11000	5800	6800	8750	15600
12000	6700	8000	10070	

The figures given by Mr. C. P. Steinmetz in his paper on the Law of Hysteresis (Am. Inst. Elect. Engrs., 1892) give additional evidence of the wide variation which this quality is liable to exhibit in different specimens of nominally soft iron.

Chemical analysis is apparently an imperfect guide in the estimation of magnetic quality, and to some extent this is intelligible enough. Puddled iron, for instance, liberally streaked with slag, may seem on analysis less pure than specimens of ingot metal which have much higher hysteresis losses. It is not improbable that much of the inferiority of which most modern sheet and wire iron undoubtedly shows in this respect may be due to traces of foreign elements which have become chemically incorporated with the metal through the use of methods of manufacture which are ill adapted to yield a good product from the magnetic point of view, however successful they are in producing a mechanically good iron. Manganese, so essential to the strength and toughness of ingot iron, is well known to be deleterious magnetically.

The makers of transformers complain that they are unable to get metal of the quality they want except by a kind of happy accident, that the conditions which bring about a good result are so imperfectly understood that they cannot be reproduced with any certainty. Much the same thing was true in the early days of mild steel, and incessant testing contributed to put matters on a surer footing. Magnetic testing is now easy for makers as well as users of iron, and it may be expected that specifications of magnetic quality, and particularly of hysteresis losses, will soon become commoner than they are. From being a mere laboratory affair, interesting only to the curious physicist, the subject has in a few years advanced to the front rank of practical questions, and affects wide commercial interests.

The form and general design of transformers has received all possible attention at the hands of engineers, but of the material which mainly determines their efficiency we apparently know very little. It is scarcely satisfactory to reflect that good makers are turning out machines which waste twice as much power as they need waste.

The author brings these remarks before the Congress in the hope that some suggestions may be made which will lead to a better understanding, as between electricians and iron makers, of the conditions which govern the production of magnetically soft iron.

---

[*] Paper read at the International Electrical Congress, Chicago.

because in so doing my honest conviction is that we are preparing the way to utilize those dynamos in every direction in which alternating current transmission is going to be developed in the next ten years. The two phase system has not only the advantage of being able to work the two phase motors, but it has the enormous advantage that it gives you two single phase circuits. You are able to work each of those with all the single phase machinery which is going to be invented in the next ten years, and at the same time you have all the advantages of the splendid work which is being done on the two phase system, and I wish that we should be able to have both of these advantages. The dynamos which are going to be put down at Niagara are capable of generating either single phases or two phases. A dynamo so constructed will give you the single phase cheaper than if it was constructed with one circuit; that is to say, there is a larger output from two single phase generators than from one single phase circuit from a single phased generator of the same dimensions.

Mr. Chairman and gentlemen, I feel that I have occupied a little more than five minutes, and in that time it is quite impossible to say one tithe of what I feel is due to the importance of the subject. I have tried briefly to summarize the results which have been arrived at by myself, and which I think all those who have been investigating with the same care have arrived at at the same time.

MR. STEINMETZ.

The chairman then introduced Mr. Steinmetz, stating that he would close the discussion. Mr. Steinmetz spoke as follows:

We have heard quite a number of able discussions on the different methods of power transmission and distribution. The largest amount of power which is distributed and used in the United States to-day is distributed by continuous current. I am speaking of the hundreds of thousands of horse power used to propel our street cars. That shows that the continuous current is not dead yet, and the very fact that their rotary transformers have recommended a machine to transform polyphase currents into continuous currents shows that even the advocates of the polyphase current still concede that they cannot get along without the old continuous current.

Now, with regard to the polyphase and single alternated current, it makes no difference how many phases you use, because any system of polyphase currents can be transformed into any other system of polyphase currents by using two transformers only. Furthermore, the motors of the different polyphase systems are essentially the same, worked by the same principles, and the differences which are found are rather mechanical in their nature, but not electrical. If I may be permitted to make an outlook into the future, although we do not know what to-morrow will bring, I think the system of the future will be the single phase system. Where the power is generated by a single or alternate current transmitted along a long distance wire by overhead wires the ground is perfect. There is no danger to life there, because one who touches a 20,000 volt line, whether it is grounded or not, has no chance to do it again, but if we use a single phase current in the power transmission of the future then we will have to learn many other things. We will not be troubled any more with self-induction, with capacity, but proper appliances will eliminate or abolish the effect of self-induction and capacity so that they are entirely annihilated in their effect on the line, and even the loss of energy and of resistance will not be carried any more by a less potential. In a continuous constant current for arc lighting or for any other use, perhaps we are nearer to this ideal condition than we all think.

Personal.

Mr. E. P. Roberts, of Cleveland, is about to open a school of Applied Electricity in that city, which will be conducted entirely on the correspondence method, which has lately come into very general and successful use. Mr. Roberts is well qualified to carry on this work, having graduated from Stevens Institute with the degree of Mechanical Engineer and held a number of important positions both in mechanical and electrical engineering work, as well as the associate professorship in electrical engineering at Cornell University. Mr. Roberts will still continue with his consulting firm of E. P. Roberts & Company, and has the best wishes of his friends in the electrical field for success in his new undertaking.

Legal Notes.

Attorney-General Olney in a petition filed in the Supreme Court, Washington, D. C., on behalf of the Government of the United States, asks that the franchises held by the Metropolitan Railroad Company of Washington be declared forfeited. The petition shows that on August 6, 1890, a law was enacted requiring certain street car companies operating in the District to discard horse power within two years from the passage of the bill, and to equip their lines with mechanical power, it being optional with them to choose either cable or underground electric power. July 22, 1892, the companies were by act of Congress granted an extension of time to August 6, 1893. The Metropolitan Railroad Company having neglected to comply with the law, the petitioner asks that they be brought into court and made to show cause why their charter, granted by the District government in July, 1864, should not be revoked.

Justice Hammond of the Massachusetts Superior Court has handed down his decision in the case of the Wightman Electric Manufacturing Company vs. the Union Street Railroad Company of New Bedford. This was a case brought by manufacturers in Scranton, Pennsylvania, for the price of certain car equipments furnished by contract, which the railroad company refused to use or pay for on various grounds, claiming there was fraud on the Wightman Company's part in making the contract, and on the ground that after the making of the contract the Wightman Company became insolvent and made an assignment. Judge Hammond now finds that there was no fraud, and gives a verdict for the Wightman Company in the amount of $8,239.94.

The State Electric Company of Clinton, Iowa, having discontinued their street cars and abandoned their line on North Third street, Clinton, have been sued for $15,900 for breach of contract by Pauline Williams, Amanda Gibbs and Josephine Cook, property owners affected by the abandonment of the line.

The Chattanooga Electric Light Company, which was incorporated in December, 1888, with a capital stock of $100,000, has filed a general creditors' bill in the United States Court for the benefit of the bondholders. The outstanding bonds amount to $150,000. D. J. O'Connell was named as receiver, and will take immediate charge and continue the operation of the plant.

Suit for $100,000 damages has been instituted by T. J. Preston & Company, oil manufacturers, of No. 80 River street, Newark, against the Newark Electric Light and Power Company, whose works adjoin Preston & Company's. The latter allege that their factory and stock have been damaged to the extent of $100,000 by the vibration of the electrical machinery used by the electric company.

E. W. Tolerton, attorney for the Electrical Supply Company, has filed nine answers to intervening petitions in the United States Court at Toledo in the case against the Put-in Bay Water Works, Light and Railway Company. Nearly all the petitions set up mechanics' liens for materials used in the construction of the road. Answering these, the complainant says that it is informed that a large part of the material furnished by the Cleveland Electrical Manufacturing Company, the Railway Equipment Company, Frank Hake, Bodefield Belting Company, Barbour & Starr, M. Haughton & Company, and Arbuckle, Ryan & Company was used in the construction of Hotel Victory, an organization entirely separate from the railroad company, and asks the court to order an investigation.

The Brooklyn Edison Company is Prosperous.

The Edison Electric Illuminating Company of Brooklyn have declared the quarterly dividend of 1¼ per cent. Secretary R. C. Peabody says that the outlook for the coming fall is far ahead of anything anticipated by the company. The business as compared with last year shows an increase of nearly $67,000 in business and an increase of nearly $35,000 in the surplus.

The Young Men's Institute.

On Tuesday evening, October 3, special exercises will be held in the hall of the Young Men's Institute, 222 and 224 Bowery, to formally open the educational work of the season of 1893-4.

This institution has for several years been doing a very valuable work in offering to young men engaged during the day exceptionally good evening classes in subjects bearing directly on their daily work.

Technical subjects assume a prominent place in the curriculum.

The school year continues until May, when prizes, diplomas and certificates are awarded.

The classes are open to all young men from 17 to 35 years of age.

Boston Notes.

Prof. Von Helmholtz, the eminent German savant, who has been present at the Electrical Congress in Chicago, spent a few days in Boston, where he found much to interest him. He took in the sights in and around the Hub, including visits to Harvard University, Institute of Technology, the General Electric Company's factories at Lynn, and other places. During his stay he was entertained in a manner befitting his distinguished reputation and eminence as one of the foremost scientists of the age, and expressed himself as deeply interested in all he saw.

The Newton, Mass., Street Railway Company whose system is operated by electricity and connects with the West End Railroad system of Boston, has declared a quarterly dividend of 2 per cent. besides adding $5,000 to the reserve fund. Its Watertown branch, which cost about $60,000 and was opened not long ago, is already about paying expenses.

The Thomson Scientific Club of Lynn, Mass., which was composed of employees of the Thomson-Houston Electric Company, after a most useful career is sharing in the ill effects of the general depression. For several winters series of most useful meetings at which scientific topics were introduced and discussed have been held, and gentlemen prominent in the electrical field have been the speakers. The club had a long roll of members and excellent quarters. Owing to the serious changes that have been made in the management and vacancies occurring in the ranks of the employees, the question has had to be brought up whether the club shall disband or not. At a meeting called for next week the matter will be thoroughly discussed and a decision arrived at. Some of the older members desire to see the club continue its useful work as heretofore.

It would appear as if the question as to whether an electric car track shall or shall not be laid through Brattle street, Cambridge, would never be settled. A few weeks ago there was a blockade in the city government caused by the mayor vetoing an aldermanic order authorizing the construction of such a road; then the mayor appears to have been induced to give way and sanction the order. This looked as if the work would go right ahead. But not so. President Eliot of Harvard University and Professor Charles Eliot Norton have now taken the matter up and addressed appeals to the Railroad Commissioners against granting the authority needed. Brattle street, the thoroughfare in dispute, is certainly very attractive and a desirable street on which to reside, but it is still more, according to the dictum of President Eliot, who declares "There is no other piece of road in the United States on which Washington lived for eight months, and which is also intimately associated with the lives of many American poets, orators and scholars. In fact it is a street unique, not only in Eastern Massachusetts but in the entire country. Moreover, as the result of its natural development, it is a mile of road handsome in itself because of its curves, trees and shrubberies. It is a Cambridge possession to be sure, but one held in trust for the whole country, and like Bunker Hill Monument or Independence Hall. The street will not remain a handsome one if an electric road is permitted there." Truly President Eliot waxes eloquent, yea, he almost ascends to the region of poetry, but it remains to be seen if the State Railroad Commissioners, who are hard-headed men of business, will respect these traditions of the past, or grant authority for the introduction of that modern innovation, which has no cerements of the past clinging about it, but is the very embodiment of progress.

The electric street railway business at the factories of the General Electric Company remains much the same as it has been for the past few weeks, reports to the contrary notwithstanding. A temporary slight improvement has occurred in one or two departments, but what workmen have not been laid off are working three days a week. On top of the wholesale discharging and short time, it has been determined to reduce wages from 12½ to 15 per cent. all round. Meantime the work of deporting the clerical staff from Boston to New York continues, the only alternative for declining to go to New York being voluntary dismissal. Truly it is a pathetic sight to see the thousands of unemployed with their wives and families beginning to feel the pinch of poverty, while the debilitated and decrepid Trust drags its emaciated form around and continues to keep above ground for apparently no other cogent reason than to save funeral expenses. The report of the possibility of a new Edison enterprise being organized is adding still more to the bitter pill the General Electric is at present being forced to swallow.

The first electric railway yet built in the State of Vermont was completed on Thursday last, having cost $125,000. It is the Burlington and Winooski Electric Railway. It is a single track line about five miles long and will have several branches in time. At present power is furnished for running the eight cars by the Consolidated Electric Company, but on completion of a new power station the Vermont Electric Company will supply current. The construction work was done by G. H. Gore & Company of Boston.

On Friday Judge Colt, in the United States Court at Boston, handed down his decision in which he enjoins the Milford and Hopedale Electric Company from using the Usher storage-battery, it being decided that the same is an infringement of a patent owned by the Brush Electric Company of Cleveland.

An effort is being made to bring about a consolidation between the Thomson Electric Welding Company and the American Projectile Company, the object being to place both enterprises under a single management and so reduce expenses. Should success attend the efforts of the proposers of this change a new company will be organized having a capital of $1,000,000, which would be $500,000 less than the two existing companies' combined capital. The Projectile Company holds some good contracts from the Federal Government for projectiles, but the Welding Company is not in a particularly healthy state, hence the project for consolidation.

Mr. George F. Porter, the genial and popular secretary of the National Electric Light Association, was a visitor to Boston the present week. He called at the office of ELECTRICITY, where he met with a very welcome reception. Mr. C. O. Baker, Jr., who prides himself on having a stray acquaintance here and there in New England, accompanied Mr. Porter to the Hub, and was no less welcome.

The Messrs. Thurnhauer Bros., of Paris and Berlin, one of whom represents the Thomson-Houston International Company in Europe, the other having recently identified himself with the General Electric Company in the factory at Lynn, were in Boston a few days ago, and besides calling on some old European acquaintances made several new American ones. While these gentlemen report business as being dull in Europe, it is in nothing like the state of utter demoralization that prevails on this side of the Atlantic.

"Our company has got the worst attack of the rattles I ever knew," said an officer of the General Electric Company a few days ago when speaking about the Trust and its current bedraggled plight.

The handsome new structure, to be known as the Union Depot, that is being erected by the Boston and Maine Railway Company, to accommodate all trains entering and leaving Boston for the north, is being rapidly pushed to completion, and is to be equipped throughout with electrical apparatus for illuminating and power purposes. A contract has been closed with the Westinghouse Electric Company for the entire equipment, the plant to have an aggregate capacity of 1,100 H. P. There are to be four Westinghouse generators coupled direct to compound condensing engines of 200 H. P. each. Two of these machines will supply current for 4,000 incandescent lights for the interior of the buildings, head house, etc. The other two will furnish power to the various motors which are to be installed for operating drawbridges, turntables, elevators, coal handling machinery, etc. In addition to these there will be two compound engines of 200 and 100 H. P. respectively, driving alternating current dynamos for lighting at what is called Prison Point and East Somerville, together with the track lighting and signal towers. All the engines will exhaust into an independent condenser, using sea water. A battery of twelve horizontal tubular boilers will supply steam. A striking feature of this plant will be the system of mechanical draft which will take the place of a chimney 200 feet high, which would otherwise be required. A steel stack rising only 55 feet above the ground level will deliver the flue gases at a height sufficient to clear the roof. Draft will be furnished by two large fans, each driven by a small independent engine and capable of doing the entire service when required. The hot flue gases will be drawn through economizers, and the heat thus extracted will be returned to the feed water, thus insuring corresponding economy in the consumption of fuel.

The immense express business that is done between Boston and the surrounding cities, towns and villages has assumed such proportions that it is with difficulty handled. In view of this fact, some of the capitalists who are interested in the Lynn and Boston and other electric railway systems which now extend from the various centres of population, have under consideration a plan for running freight cars over the roads for carrying express packages. The plan is meeting with the approval of many manufacturers and merchants, and when the project has been worked out in all its details it is expected promptly to be adopted. The freight cars would be run in between the passenger cars, the time schedule being so arranged that there would be no delays.

Canadian Notes.

The Department of Customs has granted the application of the Western Union Telegraph Company to land free of duty at Canso a portion of a cable which is to be used in repairing the Anglo-American Company's cable nine miles from the Nova Scotia shore.

It is reported that the directors of the Toronto Electric Light Company have obtained a controlling interest in the Hamilton Electric Light Company.

The Brantford Electric and Power Company have been awarded the contract for city public lighting for a series of five years.

Mr. John M. Goodell, editor of the *Engineering Record*, has written to City Engineer Haskins, of Hamilton, suggesting as a remedy for electrolysis that the water pipe, gas pipe or telephone cable be connected with heavy wires with the ground wire for the trolley road. In Hamilton, however, there is no ground wire, the rails being bonded and acting as a return.

The Brantford City Council has been considering proposals for the establishment in that city of a branch of the Gaynor Fire Alarm Company of Louisville, Ky. The proposals, however, were considered to be rather one sided, and the negotiations have come to naught.

The London City Council have referred back Col. Clark's application for an exclusive electric railway franchise, which virtually means throwing it overboard.

The trolley freight idea is about to have a practical application in Toronto and York township. The Toronto and Scarboro Electric Railway has made a contract with the Toronto Railway Company for right to run freight cars over the lines of the latter into the centre of the city. This will involve a rail connection being made between the lines of the railways at the Queen street and Kingston road junction.

Mr. F. W. Martin has been appointed to take charge of the plant of the Hamilton Electric Light Company. He has been for nine years in the Toronto Electric Light Company's power house under Mr. Wright, and goes to Hamilton equipped with a thorough knowledge of his business.

William Cox, of Hamilton, has invented a trolley fender. The frame of the apparatus is built of wood with a wire netting and projects in front of the car about 3 feet 6 inches, being the full width of the track. It can be raised or lowered according to the roadbed, by means of hinged eyebolts. The frame sets close to the rails and forms a wire bed on which the victim falls instead of going under the wheels.

The Finance Committee of Hamilton met on Tuesday evening to consider the offer of the Hamilton, Grey and Bruce Electric Railway Company to settle the dispute as to right of way through the city streets. The company offered to arrange with the Hamilton and Dundas Railway Company for the joint use of each other's track, the same to be free of mileage and other charges for ten years. If at the expiration of that period the company is able to pay a dividend of 8 per cent. per annum, the company will pay a rental of $200 a year until Dec. 13th, 1913, after which the rental shall be fixed by arbitration should the parties differ. Alderman Morris moved a resolution embodying the offer of the company, but fixing the mileage after ten years at $200 a mile. The motion was lost on a tie vote. Finally it was decided, on the request of the H. G. & B. solicitor, for the committee to make a report to the council, and leave the aldermen to settle the awkward question.

The electric railway service was inaugurated in Kingston last week, and everything seems in promising shape. Saturday was the last day for running horse cars for some time.

The General Electric Company intends removing its Hamilton lamp factory to Peterboro' in the course of a week or so.

A year ago Thursday the first electric car was run in Montreal, and in November the company will celebrate the thirty-second year of its existence.

General News.

What is Going on in the Electrical World.

Milwaukee, Wis.—The receiver's sale of the Milwaukee Lighting and Power Company's plant on the 11th having been declared illegal, the sale will be readvertised.

Omaha, Neb.—The Nebraska Telephone Company has completed its new metallic circuit between Omaha and Hastings, and also between Omaha and Walnut, Iowa.

Utica, N. Y.—The three years' contract of the Utica Electric Light Company with the city expires December 31. Much competition for the new contract is expected.

Atlanta, Ga.—The Atlanta Traction Company has purchased the Atlanta City Street Railway. T. B. Eelder, of the Traction Company, will continue president of the system.

Detroit, Mich.—It is stated that all the necessary financial backing for the Detroit-Toledo electric railway line has been secured, and that a company will shortly be formed to take hold of the project in earnest.

Elmira, N. Y.—An electric dynamo manufactory established here last winter by John L. Cooper and George H. Young, for the manufacture of dynamos of from one to six horse power, has had a good local trade.

Eau Claire, Wis.—M. H. Hewett, who obtained a franchise to operate an electric street railway at Eau Claire, has asked the council for an extension of time. He says he cannot commence the road until about May 1.

Salisbury, Md.—W. R. and W. T. Johnson of Milford, Del., have purchased the franchise and privileges of the Salisbury Electric Light and Power Company, whose plant was burned in April last, and will begin work at once to put in a new plant.

New York.—Corporation Counsel Clark has rendered an opinion that the Board of Electrical Control has no power to grant the Broadway cable road a franchise to lay a wire or wires in its cable conduits for the purpose of operating signals along the line.

Savannah, Ga.—There is a probability that the Tybee railroad, 18 miles long, will be equipped with electricity when the road is rebuilt.—The Brush Electric Light and Power Company has secured control of the People's Light and Power Company by purchase.

Muncie, Ind.—The Citizens' Street Railway Company and the Muncie Street Railway Company have been consolidated under the name of the first mentioned company. The work of changing the Muncie line (dummy) to an electric will begin as soon as possible.

San Francisco.—The Mid-winter Fair is receiving encouragement from all quarters. The Executive Committee received a check for $5,000 from Chicago last week in payment for the concession for the big electric tower, which the projectors desire to begin work on at once.

Plainfield, N. J.—The directors of the electric railway company have decided to extend the road down West Front street to Dunellen, and will begin work this fall. In the spring they hope to extend the road to Netherwood, when the entire city will be covered by rapid transit lines.

York, Pa.—The board of directors of the York and Dover Electric Railway Company, having approved of the surveys of the civil engineers, will take measures to ascertain the cost of the right of way, and as soon as this is settled will proceed with the construction of the road.

Elizabeth, N. J.—The New Jersey Consolidated Traction Company has applied to the board of freeholders for a franchise for an electric railway from Newark to this city. A special meeting of the board has been called for October 2, to give the applicants an opportunity of being heard.

Kingston, N. Y.—The new electric motor invented by Mr. Winkler of the United Columbian Electric Company, this city, was given a test here a few days ago which proved satisfactory to those interested. The Winkler motor works either way, necessitating only one motor to a car instead of two.

Red Bank, N. J.—The Gillett Electric Manufacturing Company, whose factory is located here, has elected these officers: Directors, Senator William J. Keyes of Somerville; Thomas Patton, Jr., of Long Branch; Joseph F. Bray, William T. Corlies and Thomas Davis, Jr., of Red Bank; president, Senator Keyes; secretary and treasurer, T. Davis.

Salt Lake City, Utah.—Col. W. J. Sutherland of London, Eng., recently visited Salt Lake. To a reporter he said: "We are delighted with Salt Lake. The street railways and electric light systems are as fine as any city can boast of. You know the electric light system is owned largely by Englishmen and we are proud of it."

Wilkesbarre, Pa.—The People's Electric Railway Company have begun work on their line from Nanticoke to Glen Lyon, Alden, and Wanamie. The officers of the new company are: President, K. M. Smith; vice-president, Henry Schappert; secretary, T. D. Garman; treasurer, John M. Garman; directors, the foregoing and George T. Morgan, Benjamin Bache and Joseph Schappert.

Montreal, Can.—The Montreal Street Railway Company, which holds an agreement extending until the year 1922 for the use of the streets of the city of Montreal, is now raising in England a loan of £140,000 on 4½ per cent. debentures £100 each. The money is required for the purpose of doubling the existing lines and for the necessary outlay required for working the system by electricity.

New Orleans.—The Great Southern Telephone and Telegraph Exchange has purchased a site for a new telephone exchange building in this city, paying $25,000 for the site. The company controls all the wires in the city and outlying districts used for telephonic purposes.—A petition signed by a number of leading citizens has been filed in the Civil District Court, enjoining the city from selling the franchise of the city and lake railroads.

Washington, D. C.—The project of building an electric railway between Baltimore and Washington, which has been lying dormant for some time on account of the monetary depression, has been revived and will now be pushed forward with energy. The syndicate which has control of the franchise is composed of Messrs. Elkins and Widener of Philadelphia, Hambleton of Baltimore, David Newbold, Charles E. Savage, Charles B. Calvert and Howard Munnikysen.

St. Paul, Minn.—F. H. Wheelock, engineer of the Franklin School, has just completed a model of a new electric fire engine, a patent for which will shortly be obtained, that seems destined to work a revolution in fire extinguishing apparatus. It does away with the use of coal, and can be put in action with one horse and one man less than the engines now in use. The engine weighs but 4,500 pounds, and is of 70 horse power. This makes the machine weigh 9,000 to 10,000 pounds less than the apparatus now in use while its efficiency is claimed to be much greater.

Terre Haute, Ind.—The *Express* states that "Fred Ray, chief engineer of the Terre Haute Street Railway Company, has perfected an improvement on the trolley wheel and harp. The one now in use makes it necessary to remove the entire pole when a trolley wheel is worn out. This causes considerable trouble, and Mr. Ray's improvement is to do away with the difficulty. Instead of the present device the improvement is made by making the harp, which holds the wheel, separate from the piece which fits in the hole. In this way a wheel can be removed by means of a set screw. Mr. Ray has also made several other improvements in the trolley."

Chicago.—One of the interesting incidents of Railway Day (16th inst.) at the World's Fair was a tug-of-war between a steam and an electric locomotive, the latter a 600 horse power machine built at the General Electric Company's works at Lynn, Mass. The steam machine was a modern Baltimore and Ohio locomotive. The contest was witnessed by a large crowd and resulted in a victory for steam. The victorious locomotive weighed 30 tons on the driving wheels, the electric 25. The former pulled and backed the latter all over the track.

Mt. Vernon, N. Y.—It is reported that the "Woolverton Glow-Arc Light Company" has purchased a site here for the erection of a factory, foundry, mills and laboratory, and intends commencing work at an early date. The company expects, it is said, to expend not less than $275,000, and employ not fewer than 200 hands for the first year, and also to make a like expenditure each succeeding year and increase the number of employees from year to year as the business may require. A portion of the capital stock of the company has been subscribed for, the remainder is now offered to public subscription. John E. Woolverton, the president, resides at No. 1,671 Third avenue, New York City.

Worcester, Mass.—The Consolidated Street Railway Company, since December 1, 1892, when John N. Akarman took charge as general manager, has expended $600,000 in various improvements in construction and equipment. Twenty-one miles of new track has been completed, the splendid new power house is nearly finished, and a car house with a capacity for 150 or 160 cars is nearing completion. The overhead construction for the whole system will soon be in working order. More than a hundred miles of overhead wire has been strung, the feed wire being the largest made by the Washburne & Moen Company and the longest used on any street railway in the State. $50,000 more will be expended before the road is completed.

Rochester, N. Y.—The Citizens' Light and Power Company is a new organization, capitalized at $150,000, now establishing a plant here to compete with the present lighting company whose service has not been altogether satisfactory. The company will at present supply light from two Westinghouse incandescent and two Western electric dynamos, but a large amount of special machinery, including dynamos for a multiphase system, will be added. The officers of the new company are: President, Robert M. Myers; vice-president, H. Wheeler Davis; secretary, E. M. Higgins; treasurer, P. V. Crittenden. J. A. Olmstead will be superintendent.—Another new electric company, the Central Light and Power Company, has been established here with a capital of $25,000. Its officers are: President, I. W. Butts; vice-president, H. L. Barker; secretary, F. S. Macomber; superintendent, G. A. Clark.

The New Factory of the Electrical Storage Company of Philadelphia.

The Electrical Storage Company of Philadelphia has begun the erection of a new factory for the manufacture of its storage-battery cells. The location of the building is near the Germantown Junction on Allegheny avenue Philadelphia. The present factory of the company, at Gloucester, proved too limited for the fast-growing business of the concern and a more commodious structure having better shipping facilities, became a necessity.

The company manufactures what is known as the chloride accumulator, a modified form of the Laurent-Cely storage cells, which is widely used in France and on the continent of Europe. These cells are used in more than twenty sub-stations in Paris and supply the electricity which lights a large part of the French metropolis and propels a number of the street cars. The electrical current is generated at a distance, is brought into the city at a high potential, and is used to supply the storage cells of the sub-stations. From the cells thus charged the current is conveyed at a pressure of 110 volts to the motor and lights in the immediate vicinity. The advantages claimed for this arrangement are numerous, not the least being the saving of copper wire and costly underground service. The electrical generators are situated at convenient points as regards low cost of real estate and facility in procuring coal. A single line of conductors supplies all the sub-stations and it is unnecessary to keep the machinery in motion night and day to supply occasional calls for the current at unusual times. On one occasion the Government inspector ordered all work at the central power station to cease for 72 hours while an inspection of the boilers was being made. During this period the surplus energy stored at the sub-stations was called on, and no diminution of the amount of electricity supplied to the customers was necessary. For three days the storage cells supplied all the current used in the portions of Paris supplied by this service through the energy stored in the accumulators. The Germantown electric lighting station has used the chloride accumulator with great economy, due chiefly to the fact that it was necessary to run only a part of each day of 24 hours, instead of maintaining a continuous service of engineers and firemen.

The principal officers of the company are W. W. Gibbs president, Herbert Lloyd general manager, with offices in the Drexel Building, Philadelphia.

Incandescent Lamp Cord Adjuster.

The accompanying cuts show the design and shape of a very cheap and efficient adjuster for incandescent lamp cords, the same being a device for which there has long been a demand. To secure public recognition a device of this kind requires to be both cheap and capable of easy attachment. There are two points of excellency about this invention which recommend it to all, for it is so cheap that no one can afford to be without one, while by its aid an incandescent light can be instantly adjusted to any position within its range, the cord being held firmly without the slightest wear or tear.

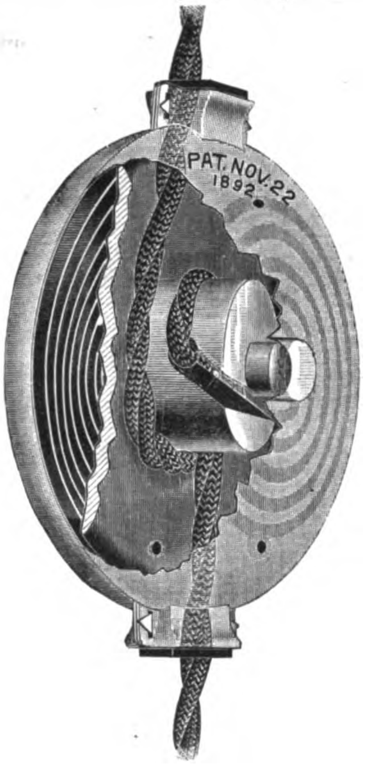

FIG. 1.

As may be seen from the cuts, this device, unlike others on the market, can be placed in position almost instantly without detaching the cord from lamp socket or rosette, thus saving time and annoyance. It is made in unique design, very light and compact, there being no heavy weight for the cord to support, and is guaranteed to fill every claim made for it.

In describing this apparatus, we would refer to the cuts Fig. 1, showing the adjuster attached in position on a cord, with a part of the brass shell removed to show the wood spindle with the cord slot through which it passes, with the cord in position, one flange on the wood spindle being partly broken away to show a position of the regulating spring. Fig. 2 shows the adjuster with one-half the brass removed, these shells being made of brass and stamped into shape. The two halves have small slots and points conforming the one to the other so that when the inner spring and wood spindle all have been placed in position the two brasses are placed together and secured. When placing the cord in position on the wood spindle the latter is held in position by a brass pin, the cord is pressed to back of the slot in spindle, the two brass shells are then pressed together and made secure, the pin is withdrawn and the adjuster is ready for use. The exact tension required is secured by regulating the spring with the hand before closing the apparatus, which can be placed at any point on the cord by simply being raised or lowered by the hand, the cord slipping through the slot without injury. This device is made in two sizes, No. 1 adjusting from 0 to 30 inches, No. 2, from 0 to 9 feet, and can be had from Stephen Porter & Company, 384 Atlantic avenue, Boston.

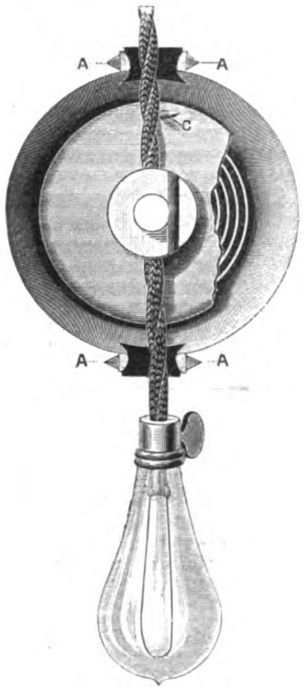

FIG. 2.

Important Notice.

Owing to the assignment of the Ansonia Electric Company and the pending settlement of their affairs, the Stanley Electric Manufacturing Company have decided for the present to sell their goods direct to users, and for this purpose have established an office in the building, 102 Michigan avenue, Chicago, and put same in charge of Mr. John H. Noble. They are prepared to furnish transformers, delivered in Chicago as heretofore, if preferred. They will carry a full stock of transformers of all standard voltages, and orders sent to the Chicago office will receive prompt and intelligent attention. Address all communications to the Stanley Electric Manufacturing Company, 102 Michigan avenue, Chicago, Ill.

COMMERCIAL PARAGRAPHS.

Queen & Company, Incorporated, recently secured an order for the testing outfit to be used by the Philadelphia Traction Company in its new power house at Thirteenth and Mount Vernon streets. This is a very satisfactory testimonial for the Queen apparatus, as a similar contract was executed between the same parties last year.

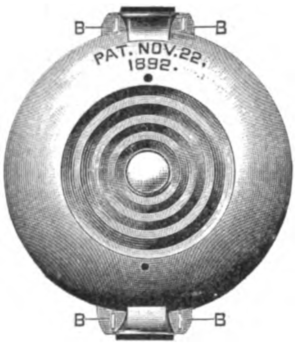
The Beacon Vacuum Pump and Electrical Company, owners and manufacturers of the "New Beacon" lamp, not only have no reason for complaining of depression in trade, but are jubilant over the prosperity they are enjoying. Though their new lamp has been before the public for only a few weeks, the demand has grown so great that the company has had to increase its factory facilities to a capacity of 8,000 lamps per diem, and even then finds difficulty in keeping up with its orders. When introducing the "New Beacon," the Beacon Company declared its intention of licensing at most six outside companies to manufacture the new lamp under royalty. Such an arrangement has been so promptly availed of that the last of these prospective licensees is now being negotiated with, which means when the negotiations are completed that there will be a tremendous daily output of the new lamp.

INCORPORATIONS.

The Natchez Light, Power and Transit Company, Natchez, Miss.—to manufacture and sell electricity for light, heat, power or any other purpose, and to distribute the same either in storage batteries or by poles and overhead wires, etc. Capital stock, $200,000. Incorporators: Maurice Moses and Abraham Moses, Natchez.

The Consumers' Electrical Supply Company, New York City—to manufacture electrical supplies. Capital stock, $1,000. Directors: Harold G. Martin, Elbert Brussel and Julian A. Moses, of New York City.

The Electric Experimental and Developing Company, of New York City—to acquire inventions having relation to the various parts of a system of electric light and power. Capital stock, $100,000. Directors: William E. Mandelick, W. B. Vandewater and Alick G. Macandrew, of New York City.



The North Scranton Transit Company, Scranton, Pa.—to build and operate an electric railway. Capital stock, $50,000. President, John H. Fellows. Directors: A. Weinschenk, J. George Eisele, Louis Morel, Jacob K. Johler and Hanson Carpenter, Scranton.

The Canton, Sparrow's Point and North Point Railroad Company, Baltimore, Md.—to build and operate an electric railway from Canton to Sparrow's Point. Capital stock, $500,000. Incorporators: Frederick W. Wood, president of the Maryland Steel Company; Joseph R. Foard, of the Joseph R. Foard Transportation Company; T. Wallis Blakistone, counsel for the Central Passenger Railway Company; and Walter B. Brooks, Jr., all of Baltimore City; and Major Luther S. Bent, president of the Pennsylvania Steel Company, of Steelton, Pa.

The Gladstone Electric Lighting and Power Company, Gladstone, Mich. Capital stock, $50,000. Incorporators: John W. Kendrick and John Woods, of Minneapolis; Edwin S. Tice, of Gladstone, and Richard H. Ralph, of St. Paul, Minn.

The Leroy Electric Light, Power and Heating Company, Leroy, Ill.—to supply electric light, heat and power. Capital stock, $10,000. Incorporators: L. A. Crumbaugh, A. J. Keenan, L. A. Reynolds, Amos Rutledge and S. D. Vandeventer.

The Royal Columbian Electric Company, Chicago, Ill.—to deal in electrical machinery and appliances for heat, light and power. Capital stock, $50,000. Promoters: H. H. Natwick, J. I. Stene, H. R. Fish, Jr.

The Des Moines Rapids Power Company, Hamilton, Ill.—to acquire water power, erect and operate street railways, electric lights, etc. Capital stock, $500,000. Incorporators: Lewis W. Cass, James Anthony, Charles B. Holmes and H. C. Reiner, of Keokuk, Iowa.

The Atlantic Electric Manufacturing Company, of Brooklyn, N. Y.—to sell and manufacture electrical apparatus. Capital stock, $100,000. Directors: Warren P. Freeman, Albert T. Schlichting, Julius Smith, all of Brooklyn.

The West Side Electric Light Company, Scranton, Pa. Capital stock, $10,000. Incorporators: John C. Haddock, C. W. Haddock, George W. Shonk, T. R. Phillips, Richard Clark and J. B. Davis, of Scranton.

The Capitol Electric Company, Hartford, Conn., to deal in electrical supplies, etc. Capital stock, $2,000. Incorporators: Ernest C. Wilcox, Meriden; Lawrence F. Furlong, Joseph P. Tuttle, Hartford.

The Johnson Sub-Trolley Company, of New York City—to acquire inventions having relation to the various parts of systems of electric railway traction. Capital stock, $25,000. Directors: Edward H. Johnson, Eugene H. Lewis and Charles B. Coster, of New York City.

The C. H. Brown Electric Battery Company, Portland, Ore.—to conduct a general business for supplying light, heat and power by means of electricity. Capital stock, $100,000. Promoters: Chas. H. Brown, A. P. Armstrong, Thos. Walker, Louis Prager, Chas. E. Wilber, Jas. Posey, Thos. M. Rogers, Thos. R. Demarest, Portland.

The Bevier Electric Light Company, Bevier, Mo.—to erect an electric light plant. Capital stock, $15,000. Promoters: J. A. Bovard, J. H. Bovard, J. C. Stearns, Kansas City, Mo.

Hicks-Troy Electric Door Company, Chicago, Ill.—to manufacture and deal in electric doors and devices. Capital stock, $250,000. Promoters: Oliver H. Hicks, Robertus F. Troy, Robert McCurdy.

The Lewis Electric Company, Jersey City, N. J.—to manufacture, use and distribute electricity for light, heat and power. Capital stock, $1,000,000. Promoters: I. N. Lewis, Fort Wadsworth, S. I.; V. H. Bridgman, Fort Schuyler, N. Y.; W. S. Fanshawe, Westchester, N. Y.; H. E. Fanshawe, Morristown, N. J.

The Boughton Telephotos Company of Buffalo, N. Y.—to manufacture a device known as "the Boughton Telephotos," being an instrument designed to communicate by signal between long distances. Capital, $125,000. Directors: George B. Van Vleck, Claudius V. Boughton, George Sandrock, Albert J. Wheeler, Andrew F. West, Thomas N. Jarvis and William L. Marcy, of Buffalo.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED SEPTEMBER 5, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

504,405. Trolley-Wire Cleaner. Mahlon Shaaber, Reading, Pa., assignor of one-half to Jacob S. Ammon, same place. Filed June 19, 1893.

504,549. Conduit Electric Railway. Benson Bidwell, Philadelphia, Pa., assignor, by mesne assignments, of one-half to Benson Bidwell, trustee. Filed Sept. 4, 1884.

504,676. Conduit for Electric Railways. Samuel H. Flagg, Providence, R. I. Filed Aug. 24, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

504,475. Pendent Incandescent Electric Light. William A. Johnson and John C. Davidson, Prince's Bay, N. Y., assignors to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed April 28, 1893.

504,578. Flash-Light Apparatus for Photographers' Use. Joseph N. Harrison and Henry J. Harrison, San Francisco, Cal. Filed June 8, 1891.

504,632. Electric-Arc-Lighting System. Thomas Spencer, Philadelphia, Pa. Filed Feb. 18, 1893.

504,681. Electric Car-Lighting System. Isaac N. Lewis, Fort Wadsworth, N. Y. Filed Sept. 17, 1892.

DYNAMOS, MOTORS, ETC.

504,379. Commutator for Dynamo-Electric Machines. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Nov. 1, 1892.

504,401. Armature for Dynamo-Electric Machines. John T. Morrow, Lynn, assignor to the General Electric Company, Boston, Mass. Filed May 13, 1893.

504,484. Electric Locomotive. Augustin I. Ambler, Washington, D. C., assignor to Roseline N. Ambler, same place. Filed Sept. 16, 1892.

504,492. Electric Automatic Steam-Governor. Edgar A. Edwards, Cincinnati, Ohio. Filed Dec. 2, 1891.

504,497. Method of and Apparatus for Regulating Alternating-Current Dynamos. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company, of Maine. Filed Jan. 19, 1891.

504,630. Method of Operating Electric Motors by Alternating Currents. Alexander Siemens, London, England, assignor to Siemens & Halske, Berlin, Germany. Filed Oct. 21, 1890.

BATTERIES.

504,370. Secondary Battery. William L. Silvey, Lima, Ohio. Filed July 8, 1892.

504,455. Storage-Battery. Charles J. Reed, Orange, N. J. Filed March 2, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

504,367. Condenser Telegraph System. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Feb. 8, 1889.

504,454. Telephone-Tansmitter. Nathaniel Parks, Deansville, N. Y. Filed Dec. 6, 1892.

504,461. Switchboard for Telephoning Purposes. Upton H. Balsley, Philadelphia, Pa. Filed June 8, 1889.

504,636. Telephone Apparatus. Alfred Stromberg and Andrew Carlson, Chicago, Ill. Filed April 3, 1893.

SWITCHES, SWITCHBOARDS, ETC.

504,345. Multiple Switchboard Apparatus. William M. Goodridge, Highland Park, assignor to the Western Electric Company, Chicago, Ill. Filed Jan. 12, 1889.

504,523. Double Pole Switch. Charles W. Gartside and Robert E. Wood, Baltimore, Md. Filed June 29, 1893.

504,528. Electric Switch. Albert B. Herrick, Schenectady, N. Y., assignor to the General Electric Company, Boston, Mass. Filed July 21, 1892.

SIGNALS AND SIGNALING APPARATUS.

504,542. Electric Railway Signal. Frank E. Seagrave, Toledo, Ohio. Filed Jan. 26, 1892.

MISCELLANEOUS.

504,335. Temperature Indicator. Charles E. Egan and Fred M. Bailey, Chicago, Ill.; said Egan assignor to said Bailey. Filed March 13, 1893.

504,336. Electric Belt. William C. Ekholm, Joliet, Ill. Filed June 19, 1893.

504,344. Thermal Cut-Out. William M. Goodridge, Highland Park, assignor to the Western Electric Company, Chicago, Ill. Filed Nov. 19, 1887.

504,397. Electric Conductor. Joseph W. Marsh, Pittsburg, Pa. Filed Aug. 8, 1892.

504,398. Electric Conductor. Joseph W. Marsh, Pittsburg, Pa. Filed Aug. 8, 1892.

504,462. Electric Lock. Lemuel B. Tinkham, Quincy, Mass. Filed May 12, 1892.

504,496. Electric Welding Apparatus. Hermann Lemp, Lynn, Mass., assignor to the Thomson Electric Welding Company of Maine. Filed June 25, 1890.

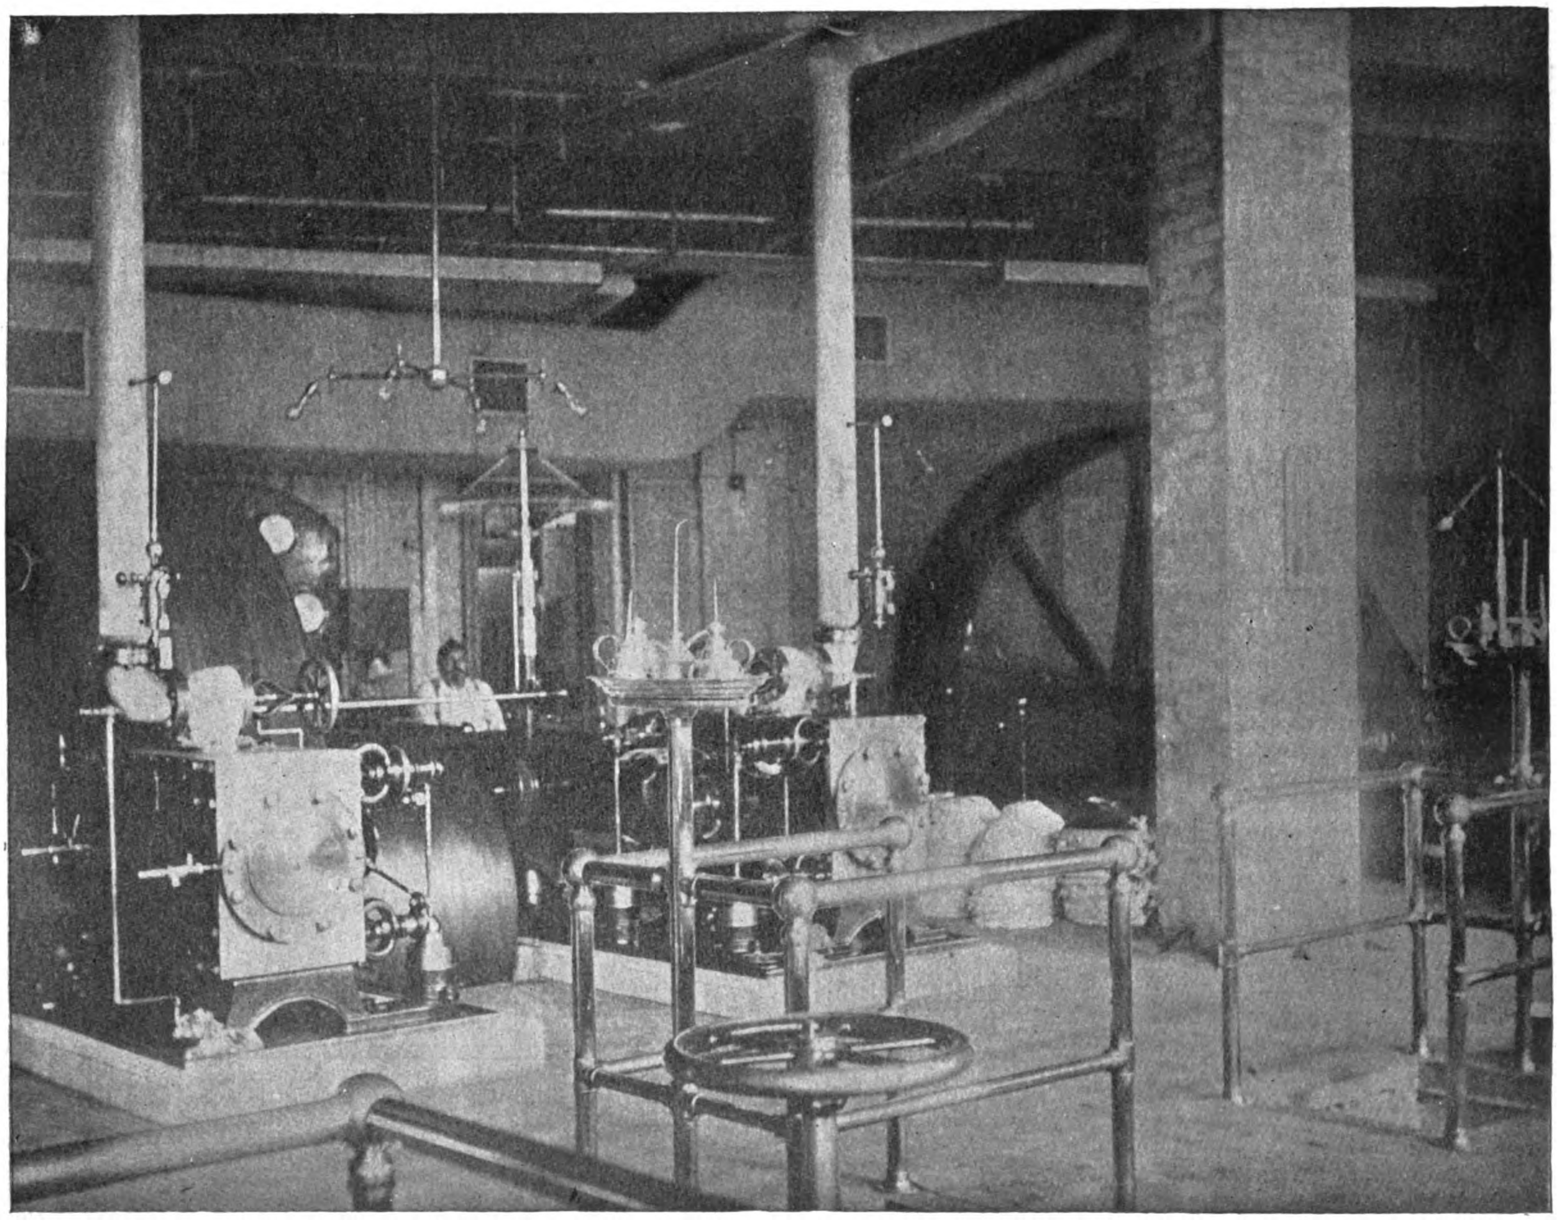
504,671. Musical Instrument. Constant Doriot, Philadelphia, Pa., assignor of one-half to John R. Painter, same place. Filed April 17, 1893.

RE-ISSUE.

11,364. Electrically-Heated Soldering Iron. George R. Meitzler, Cincinnati, Ohio, assignor of one-half to William H. Osborne, Prince's Bay, N. Y. Filed July 3, 1893. Original No. 490,256, dated Jan. 17, 1893.

ELECTRICITY.

VOL. V. NEW YORK. OCTOBER 4, 1893. CHICAGO. No. 12



DYNAMO ROOM.--"NEW YORK HERALD" BUILDING. (SEE PAGE 188.)

Electricity and Its Uses in a Modern Newspaper Office.

"The New York Herald" Building.

The New York *Herald*, following the uptown march of business, has been the first of the New York dailies to establish itself within the more modern centre of trade and to break away from the historical Newspaper Row. Its new home, at the junction of Broadway and Sixth avenue, at Thirty-fifth street, now almost completed, is one of the most ornamental structures in that neighborhood, and aside from its handsome exterior and finish it presents an equally well arranged and handsome interior very much at variance with the traditional newspaper office.

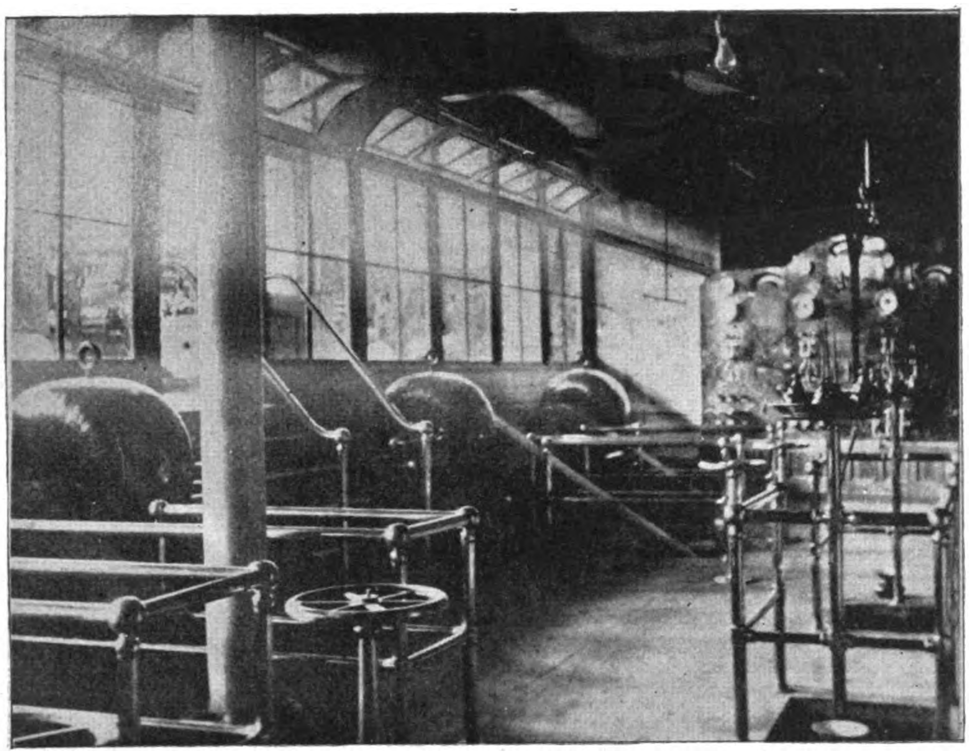


FIG. 1.

The building, which is occupied exclusively by the *Herald* and its allied branches, is a notable departure from the modern sky-scraping style of architecture, having but three stories, including the ground floor. Considering its large area and comparing it with the twelve and fifteen story office buildings which abound downtown, the *Herald* Building appears almost modest at first glance before the handsome details of the structure are appreciated.

The interior arrangements are designed entirely with reference to the requirements of the paper, and it is equipped with every kind of machinery and apparatus which enters into the work of turning out its large daily editions.

The electrical part of the plant, which will be of the most interest to our readers, forms quite a large proportion of the mechanical equipment of the building, and besides the lighting plant considerable use is made of electric power in almost all of the numerous departments of the paper.

The engine and dynamo room is situated on the Broadway side of the building, but separated from the street by the press rooms of the *Telegram*. Unlike the average engine room, it is well lighted, the partition on one side being entirely of glass. Facing the back of the room are four Watts-Campbell engines aggregating 700 horse power in capacity. The two central engines are connected on a common shaft carrying one driving wheel, and the outside ones have each a separate driver.

These engines are all belted backward to a countershaft in the basement below (see Frontispiece), and from this the belts run through the floor to the four Mather generators situated on the opposite side of the room from the engines, and shown in Fig. 1. The latter have a capacity of 55 kilowatts each, and are compound wound machines, running at 110 volts pressure.

The wiring is arranged to be used for either a two or three wire distribution, the middle wire being twice the section of the outside lines. The house plant is run on the two wire system, but in case of emergency the entire plant or any part of it can be thrown on to the street main from the Edison station. The method of changing from the house circuit to the street system is shown in Fig. 2. Each circuit in the building is connected at this switchboard to a double-throw switch, one side of which makes connection with the house plant and the other side with the street system.

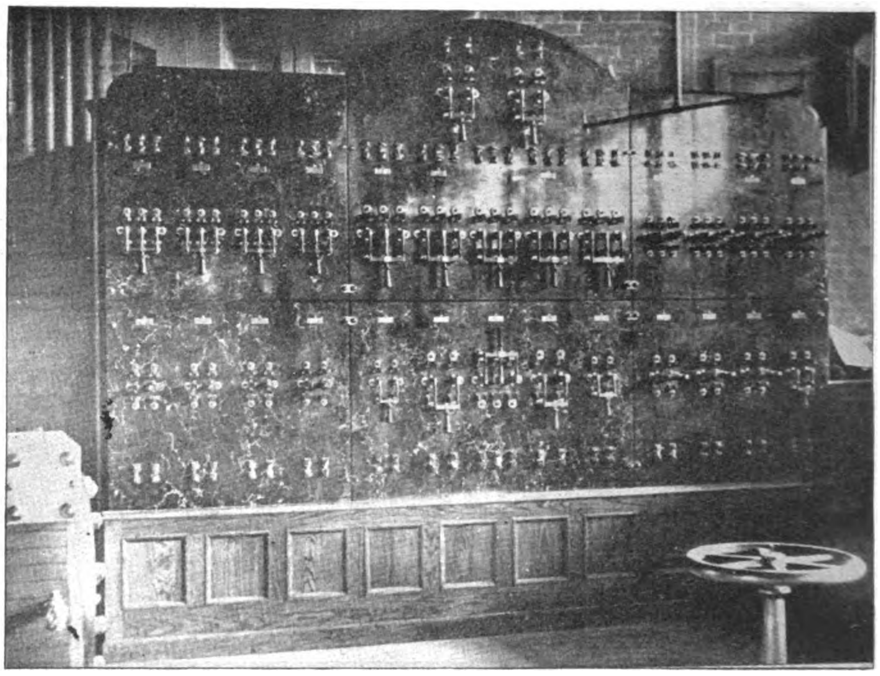

FIG. 2.

The room contains two switchboards, each 14 feet long by 7 feet 6 inches high. The one just mentioned contains 14 double-throw knife switches for the lighting circuits, and 14 of the same pattern for the motor circuits.

The other board, shown in Fig. 1, contains the generator switches and usual electrical apparatus. The instruments for the separate machines are of the Mather type, and those on the main circuit are Weston instruments. The circuits are all of Habershaw wire run in vulca duct.

The building is wired for about 2,600 lamps, a number of which will be used on the outside for ornamental purposes.

One feature will be a large sign composed of miniature lamps to be placed in front of the building, reading "New York Herald." Another novelty will consist of 26 bronze owls to be placed at equal distances around the cornice, their eyes being formed of incandescent lamps. These lamps are connected to an automatic switch, which is operated by a clock, partly shown at the right hand of the switchboard, Fig. 2. This clock runs in synchronism with the large clock on the building, and is so arranged that at every half hour after the lights are turned on the switch causes the owls' eyes to blink.

Outside of the dynamo room the electrical plant can hardly be said to be of any particular system, as the machines of at least half a dozen different manufacturers may be found throughout the building.

An interesting application of electricity is also to be found in the photo-engraving department, shown in Fig. 3. In copying drawings for illustrations the arc lights shown in the cut are used exclusively, and in this way this department is entirely independent of the state of the weather. The same lamps are also used for printing sensitized paper.

Throughout the building electric motors are provided for running all the machinery, although the three 40 horse power motors for running the three large presses are held in reserve and only used in case of emergency. On account of the absolute necessity of putting the operation of these presses beyond accident three independent sources of power are provided. They are run ordinarily by steam power, but in case of any accident to that the electric motors can be connected and run from the house plant, and as a third resource the motors can be switched on to the street system independent of any power in the building. These motors are of the Mather type, as is also a 15 horse power one which is used to run a color press.

The Detroit Company are represented by two 10 horse power motors used in the stereotype room and two 5 horse power motors in the matrix room. These are used to run the machines which first take an impression on a specially prepared paper from the type after being set and which is then used as a mould in which the type metal is cast, producing cylindrical plates from which the paper is printed.

The photo-engraving department uses one 10 h. p. motor for running a circular saw and drills, and two 5 h. p. motors are used to run five linotype machines, by means of which an operator sets type by manipulating a keyboard similar to that of an ordinary typewriter.

A 10 h. p. Waddell-Entz machine is used to run a paper wetting machine through which the paper passes before going to the press.

All the above machines are used specially in connection with the work of getting out an edition of the paper, but besides these a number of other electric motors are in use for various purposes.

The passenger elevator and three Otis lifts for handling the large rolls of paper are run by electricity.

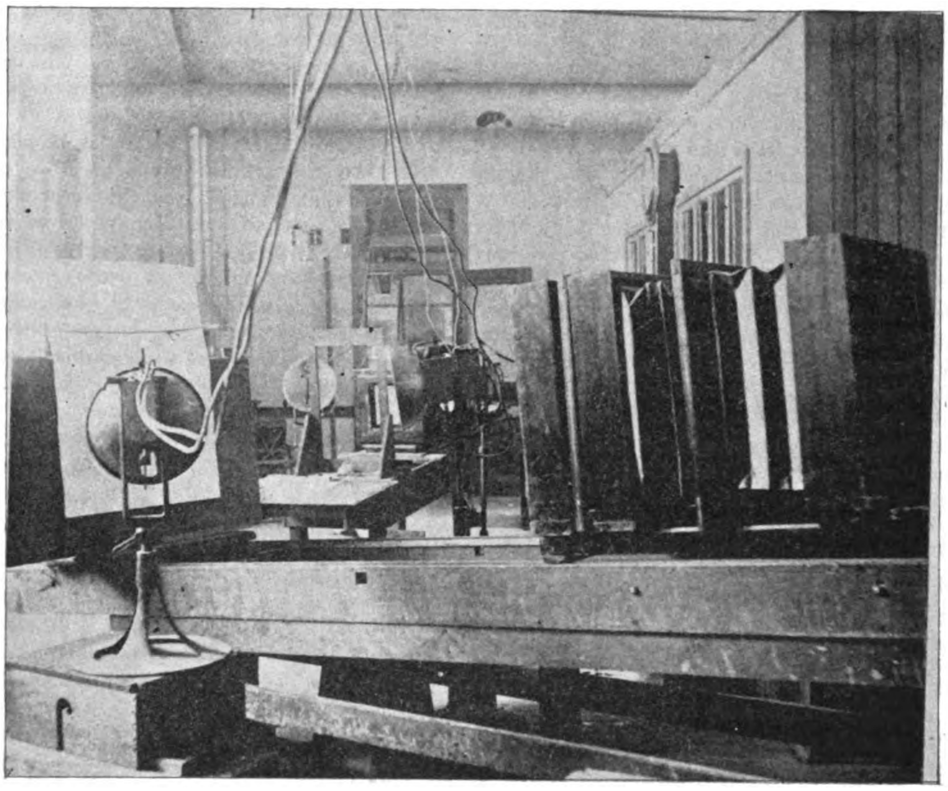

FIG. 3.

The ventilating plant is a system of exhaust pipes run with three 10 h. p. C. & C. exhaust fans and motors, and there are besides three Crocker-Wheeler motors and a Lundell motor in service.

The entire electrical equipment was installed by Hatzel & Buehler, of New York.

Altogether the motors installed aggregate 275 horse power in capacity, which is evidence of the important part that electricity plays in the mechanical work of producing a great newspaper.

Some years ago an attempt was made under the auspices of the Duc de Feltre and M. L. Vigreux to drive the dynamos at the Pointe de la Hève Lighthouse by wind power. The wind, however, as is its custom, blew when and where it listed, and ended one fine, or rather one stormy, day by overthrowing the ungainly apparatus installed on the exposed headland. M. Max de Nansouty, in alluding to this attempt to "harness" the wind, suggests that next time a similar attempt is made it would be as well to try the effect of surrounding the "atmospheric turbines" by strong towers, and directing the wind on to the vanes by nozzles in much the same way as the water is directed on to the buckets of a Pelton wheel. This idea of "canalizing" air currents is, it is said, actually engaging the attention of windmill experts.

Some of the Causes of Interruption to Telegraph Circuits.

BY F. C. ROBERTSON.*

A telegraph system, with its lines stretching over country in different directions, connecting cities, towns and villages, is to some extent at the mercy of the elements; with its batteries, instruments and wires, it is constantly subject to disturbance from various causes. The substance of this paper is a brief description of some of the common forms of interruption (usually called "troubles") which are experienced on telegraph circuits.

The troubles met with in the operation of telegraph circuits are of three kinds, and are known as "the break" (or open), "the ground," and "the cross." The circuit is said to be "open" when its continuity is broken and the current prevented from circulating, "grounded" when there is an abnormal electrical connection between the ground and the earth, and "crossed" when the line is in connection with another line upon which there is a current of electricity.

A circuit may be opened in various ways—for instance, by the breaking of the line, breaking of the magnet wire of a relay outside of bobbin, a loose connection at a binding post, displacement of plugs in switchboard, or by a key being accidentally left open. A break in the line wire generally occurs during very cold weather when the wire is contracted by the low temperature, causing a greater strain in it, and is often found at a point where the wire had been kinked, or at a joint which in making had been twisted so tightly as to cause the wire to be partially severed. Breaks are frequently caused by a tree falling on the line, which usually takes place during a violent wind storm, although sometimes through carelessness of woodmen in felling trees. Sleet storms are very destructive to the lines, owing to the excessive weight due to the ice adhering to the wires, which frequently causes them to break, or the alignment to become distorted. Poles carrying a large number of wires have frequently been known to break down under the extraordinary weight due to ice on the wires. Sleet storms general over a large area of country, of such severity as to damage lines, are fortunately of rare occurrence. The circuit is sometimes found to be open in an office, and might be traced to a broken connecting wire, broken relay wire, loose binding screw, but more frequently to an open key, or a plug out of position in switchboard. The circuit is sometimes found to be open in the battery due to a jar breaking and allowing its solution to escape, a zinc falling from its hanger to the bottom of the jar, or the wire connected to the copper element becoming detached. There is a kind of trouble which takes the form of an extraordinary and variable resistance in circuit, which is sometimes met with on old lines, the source of which is usually in a rusted joint, or a joint on a portion of the line in which there is no tensile strain. During dry weather these joints cause the resistance of the wire to be much increased, but during a rain the joints become wet, improving their conductivity.

Grounds on the wires are of more frequent occurrence than breaks or crosses. All ground faults contain more or less resistance; when the resistance of a fault is very small, the connection of the line with the earth caused thereby is comparatively perfect, practically dividing the line at that point into two circuits and preventing the current from the battery at either end of the line from passing further than the fault, but when the fault contains considerable resistance, the connection with the earth caused thereby is not sufficient to prevent a portion of the current from either battery from passing the point of fault, the working margin of current being that which finds its way past the point of fault. The circuit in such case is not totally interrupted, and signals may be exchanged between terminal offices on the circuit by properly adjusting the receiving instruments. Such a fault is called a "partial ground," or more commonly termed an "escape."

Although "single" (or simplex) circuits may be worked fairly well with a considerable and varying escape on the line (as the adjustment of receiving instruments can quickly be changed by the operator to correspond with the variations of the current), quadruplex circuits cannot be worked successfully under the same conditions; the varying escape causes the balance of the instruments to become disturbed, producing a mutilation of the signals on the receiving instruments.

A large percentage of the number of grounds which occur is found either on the lines in the towns through which they pass, or in the offices, only a small proportion being found on the lines in the country. The wire coming in contact with a foreign wire, such as a telephone, call bell, or guy wire, is a very frequent source of the trouble, though the circuit is very often grounded at the switchboard during a thunderstorm by lightning fusing the metal at the air-gap of the lightning arrester in passing over to ground. Partial grounds, or escapes, are often due to the wire touching the branches of trees, and are more susceptible during wet than dry weather, the effect of the moisture being to magnify the escape. Highway lines are more subject to escapes of this kind than lines located on the right of way of a railroad owing to the numerous shade trees which they encounter and the difficulty experienced in keeping them trimmed to clear the wires; owners of the trees as a rule object to any extensive cutting of limbs which would tend to disfigure the appearance of the trees, consequently to maintain a clearance the branches have to be frequently pruned. If this operation were neglected for a long time the effect would be manifested by the insulation of the line deteriorating. In cases where trimming cannot be done, in order to clear the line it becomes necessary either to replace the poles by higher ones, so that the wires will pass above the tops of the trees, or to divert the line by setting the poles out.

(*To be continued.*)

---

* Read at the Convention of the Canadian Electrical Association.

The British Association.

[FROM OUR LONDON CORRESPONDENT.]

The British Association, which began its sittings at Nottingham on September 13, was attended by very few prominent electrical men; consequently few papers on electrical subjects were read. Their absence is partly accounted for by the Congress at Chicago, at which some of those who usually take part in the British Association meetings were present.

In Section "A" the president, Mr. R. T. Glazebrook, in delivering his address referred at some length to the "mechanical theory of light" and the "electro-magnetic field." Lord Kelvin read two papers, one on the "Piezo-Electric Property of Quartz" and the other on "A Piezo-Electric Pile." Mr. Gisbert Kapp read one on the "Relative Cost of Conductors with Different Systems," and Mr. Albion T. Snell also read one on the "Utilization of Waste Water Power by Electricity."

In Section "G" Mr. W. B. Sayers read a paper on "Self-Exciting Armatures for Continuous Current Dynamo-Electric Machines and Compensators for the Loss of Pressure in Feeders of Electric Supply Systems." In the same section Mr. W. Worby Beaumont, M. I. C. E., delivered one on a "New Form of Variable Power-Gear for Electric Railways and Tramways."

Relative Cost of Conductors with Different Systems of Electric Power Transmission.

BY GISBERT KAPP.

(*Read before Section G, September* 18.)

It is just twenty years ago that the reversibility of the dynamo-electric machine was discovered, and with it the transmission of electrical power. The machines then and until recently employed were of the continuous current type, but within the last few years transmission of power by some form of alternating current apparatus has come into use, chiefly because it enables us to carry power to a greater distance with a moderate rate, and therefore moderate cost of conductors. The reason for this enonomy lies in the fact that owing to the scheme of commutators, and the facility and certainty with which alternating current transformers can be insulated, the effective pressure at which the current is transmitted is much greater with alternating than with continuous currents. To put it in another way, with continuous current plant the voltage is limited by the difficulty of insulating the generating and receiving machinery. With alternating current plant there is no necessity of high insulation of generators or motors, but only of the step-up and step-down transformers, and since this type of apparatus can, by the use of oil or other means, be insulated to any desired extent, it is the difficulty of insulating the line rather than the machinery which limits the voltage that can be safely employed. In comparing the various systems of transmission as regards economy of material we must put all on the same basis, by so designing the plant that there shall be in each case the same stress on the insulation, or in other words, that the difference of potential between any two points in the circuit, or between any point and earth, shall not exceed the predetermined limit. The systems of transmission which have as yet been practically employed, and which alone even claim our attention here, are the following: single-phase alternating current transmitted by two wires; double-phase alternating current transmitted by four wires; double-phase transmitted by three wires; three-phase alternating current transmitted by three wires; continuous current transmitted by two wires. The last case, although practically impossible for extra high pressures, is here included because it gives us a financial standard of comparison for the other four methods of transmission. It is well known that in every circuit the different parts of which are equally well or equally badly insulated the electrical centre of gravity remains always at zero potential, and it follows from these reasons that if the circuit carry an alternating current, the absolute potential of any point undergoes cyclical change, bringing it in turn above and below the potential of the earth by an equal amount. Thus in a circuit carrying 10,000 effective volts, the greatest potential difference between two points will be 14,000 volts, and the greatest possible value of the absolute potential will be 7,000 volts, positive or negative. The insulation to earth will, therefore, be put under a stress not exceeding 7,000 volts; if, however, one point on the line were earthed, the stress at every point would immediately rise to 14,000 volts. We can now compare the continuous and single-phase alternating current as regards weight of copper required for the line, assuming in both cases the same total power and the same efficiency of transmission. Let us fix the greatest permissible stress at 7,000 volts from the earth, then it will be immediately clear that the effective voltage of transmission in the case of the alternating current is 10,000 volts and in the case of continuous current 14,000 volts, and since the weight of copper for equal efficiency conditions varies inversely as the square of the pressure, it follows that the transmission of power with alternating current requires twice as much copper as continuous. With two-phase currents and completely duplicated circuits, i. e., four wires in a line, the same holds good, as will be obvious on considering that each circuit half the power, but how does the case stand if we bunch two of the wires? In this case we have half the current in each of the external wires and about 70 per cent. of the current in the middle wires, resulting apparently in a saving of copper, but this is a fallacy; not only is there no saving of copper, but we require actually more copper than with a single-phase system, or the four-wire double-phase system; the reason being that if we tie two of the terminals together we forcibly displace the electrical centre of gravity of each circuit, causing the potential of the other terminals to vary between wide limits. To keep the stress on the insulation down to the given limit, we must therefore lower the voltage of each circuit, and this means that we must use more copper in the line. Similar investigations made for the three-phase system show that the effective voltage in each circuit must be lower than with a continuous current, but may be higher than with a single-phase alternating current. I shall not occupy time by giving the mathematical investigations of the various cases previously mentioned, but will simply state the practical result. If we put all the systems on the same footing as regards efficiency of insulation we find the following: If for the transmission of a certain power over a given distance by continuous current 100 tons of copper are required for the line, then the single-phase alternating and the two-phase four-wire system will require 200 tons, the two-phase three-wire system will require 290 tons, and the three-phase three-wire system only 150 tons. As far as the line is concerned there is thus a distinct advantage in the employment of the three-phase system.

On a Piezo-Electric Pile.

BY LORD KELVIN.

(*Communicated to Section A, September* 15, 1893.)

The application of pressure to a voltaic pile, dry or wet, has been suggested as an illustration of the piezo-electric properties of crystals, but no very satisfactory results have hitherto been obtained, whether by experiment or by theoretical considerations, so far as I know. Whatever effects of pressure have been observed have depended upon complex actions on the moist or semi-moist substances between the metals and electrolytic or semi-electrolytic and semi-metallic conductances of the substances. Clearing away everything but air from between the opposed metallic surfaces of different quality, I have made the piezo-electric pile which accompanies this communication. It consists of twenty-four double plates, each 8 centimetres square, of zinc and copper soldered together, zinc on one side and copper on the other. Half a square centimetre is cut from each corner of each zinc plate, so that the copper square is left uncovered by the zinc at each of its four corners. Thus each plate presents on one side an uninterrupted copper surface, and on the other side a zinc surface, except the four uncovered half square centimetres of copper. A pile of these plates is made, resting one over the other on four small pieces of indiarubber at the four copper corners. The air-space between the opposed zinc and copper surfaces may be of any thickness from half a millimetre to 3 or 4 millimetres. Care must be taken that there are no minute shreds of fibre or dust bridging the air space. In this respect so small an air-space as half a millimetre gives trouble, but with 3 or 4 millimetres no trouble is found.

The lowest and uppermost plates are connected by fine wires to the two pairs of quadrants of my quadrant electrometer, and it is generally convenient to allow the lowest to lie uninsulated on an ordinary table and to connect it metallically with the outer case of the electrometer.

To make an experiment (1) connect the two fine wires metallically, and let the electrometer needle settle to its metallic zero.

(2). Break the connection between the two fine wires, and let a weight of a few decigrammes or kilogrammes fall from a height of a few millimetres above the upper plate and rest on this plate. A startlingly great deflection of the electrometer needle is produced. The insulation of the indiarubber supports and of the quadrants in the electrometer ought to be so good as to allow the needle to come to rest, and the steady deflection to be observed, before there is any considerable loss. If, for example, the plates are placed with their zinc faces up, the application of the weight causes positive electricity to come from the lower face of the uppermost plate, and to deposit itself over the upper surface of plate and weight and on the electrode and pair of quadrants connected with it.

On a New Form of Variable Power-Gear for Electric Railways and Tramways.

BY W. WORBY BEAUMONT, M.I.C.E.

It is a matter of great importance on electrical railways and tramways that the maximum steam-engine power at work in the generating station should be as little above the mean load as possible.

It is found on electrical railways now at work that there is a great waste of power, and therefore of fuel, in consequence of the large consumption of current in getting the trains into motion by motors attached directly to the axles. On the South London Railway it is found that the power employed electrically in overcoming the inertia of the train is from 25 to 50 and 60 per cent. greater than that required to keep the train going.

Mr. J. H. Greathead, M.I.C.E., the engineer of this railway, has shown that if this could be avoided from 20 to 30 per cent of the engine power which must under present conditions be kept running might be shut down. The author shows this by diagrams representing the variation in the consumption of power in the working of this railway, as given by Mr. Greathead.

For several reasons the employment of geared locomotives is undesirable on railways, although single-reduction gearing is most generally adopted for tramways, and probably will remain best for that purpose. The noise made by high-speed gearing and the wear are both objectionable, otherwise a geared locomotive offers the means of overcoming to some extent the losses referred to.

In the paper the author shows how an intermediate course can be adopted which will entirely remove the loss of power at the generating station. The electric motor is placed directly on the driving axle, but is reduced in size and power to more nearly that of the mean horse-power required on the road. This for the greater part of the journey of a train from station to station drives the axle upon which it is placed at its own speed, just as those do which are now upon the South London Railway. The motor is, however, on a hollow spindle, which drives the axle, when starting a train, through the medium of a compact double clutch containing one pair of epicycloidal reducing wheels. The clutches are operated by electro-magnets or by fluid pressure.

The train or locomotive may by this means be started at from one-fourth to one-seventh of the speed of the motor. After a few seconds, the inertia of the train having been overcome, the motor, the clutch-gear, and the driving-axle are solidly coupled, and all move as one piece, the gearing only working during the starting of the train.

The motor may thus run idle upon the axle, or may drive the latter at one-seventh of its speed, or at its own speed. A breakdown leaves the locomotive in the condition of a gearless engine.

For tramcars similar apparatus is described in the paper, which will drive the car by a direct motor with starting ratio of gear of about six to one, or by single reduction gearing will drive the car either at the usual gear ratio of about four to one, or, for starting, at a ratio of about twenty-four to one.

Honorable Mention.

At a recent meeting of the directors of the Electric Gas Lighting Company, Boston, the following resolutions were adopted :

Whereas Louis W. Burnham, Vice-President and General Manager of the Electric Gas Lighting Company, departed this life August 9th, after a brief illness; and

Whereas the Board of Directors of the company desire to put on record their high appreciation of their deceased associate and deep sense of the great loss which the Board and the company has sustained; therefore,

Resolved, That in the decease of one who has been so constant, so able and so indefatigable in developing and advancing its interests this corporation has lost an officer whose strength, energy and integrity of character were invaluable; and the Board has lost a member for whose manly character his associates entertained a high personal regard, and upon whose aid in their common duties they have long and confidently relied.

Resolved, That the Directors hereby tender to the family of their late associate their heartfelt sympathy in their sudden bereavement.

Resolved, That these resolutions be extended upon the records of the corporation, and a copy of the same be sent to the family of the deceased.

His innumerable friends throughout the country will readily appreciate the appropriateness of this tribute to the memory of Col. Burnham, who stood deservedly high in the esteem of all who had been at any time,brought into personal contact with him, or were numbered among his acquaintances.

Materials for Wire Standards of Electrical Resistance.

BY DR. STEPHAN LINDECK.*

More than thirty years ago Werner von Siemens proposed to fix the practical unit of electrical resistance by such a definition that by referring back to the units of length and mass, and by the use of mercury, an element chemically and physically so well defined, the unit could always be reproduced with exact accuracy.

This proposition at the time was greatly opposed, but its correctness in the course of years has been proved more and more, and is demonstrated in the most striking manner by the fact that this proposition is suggested for International approval at the present Congress as a further development of the resolutions passed at the Congresses in Paris in 1881 and 1884.

The accurate reproduction of mercury resistances, as is well known, requires great care, and the use of the same is therefore limited to a few well arranged laboratories. The question still remains, which material according to modern experience is most suited for secondary wire standards, which are nearly exclusively used for practical measurements. This question was first considered by the Electrical Standards Committee of the British Association in the beginning of the sixties. The committee resolved to make copies of a German silver resistance, which has been absolutely determined out of various alloys, and to adjust therefrom ten unit coils, whereof two respectively consisted of platinum-silver, gold-silver, platinum-iridium, commercially pure platinum and mercury. It was expected by the choice of so many different materials to be assured that the result of the absolute determination could not be lost.

For the material used for the copies, which were distributed by the committee, the platinum-silver alloy was chosen. Dr. Matthiessen, to whom this work was entrusted, recommended the material on the strength of the investigation of several years, and it has been greatly used since for standard resistances in England and in this country; nevertheless it is not possible to rely absolutely upon the constancy of a resistance standard made of this material.

Entirely independent observations have proved that the value of a resistance made out of platinum-silver has constantly diminished in a period of two and one-half years. The changes remain, it is true, between the hundredths of one per cent., nevertheless they exceed the limits allowed for standards.

The question as to the most suitable material for wire standards was again taken up at the Congresses in Paris of 1881 and 1884. Dumas called attention to the alloy of platinum and iridium, of which material the standards of the meter and the kilogramme also consist.

In how far this alloy is appropriate for wire standards of resistance has been investigated by Dr. Klemenoii in an interesting paper published in 1888, which at the same time embraced the study of several other alloys, as German silver, nickelin and platinum-silver.

Of special interest are his researches on the influence of mechanical stress on the resistance of a wire. It is a known fact among the manufacturers of electrical resistances that during the winding up of the coil and in the time subsequent to the winding considerable changes occur which diminish but can be observed even after some years; that material, of course, will be most suitable of which the specific resistance is altered in the least degree. The following conclusions are arrived at by Dr. Klemenoii on the basis of his extensive researches, which cover the specific resistance, coefficient of temperature, thermo-electromotive force against copper, and the influence of mechanical deformation of the different alloys, namely, platinum-iridium, platinum-silver, nickelin and German silver. The first two are the most appropriate. The platinum-silver, however, must be preferred on account of its small coefficient of temperature (0.12 per cent. against 0.027 per cent). The next best would be nickelin. (It is to be regretted that chemical analysis of these materials has not been made). However, it is a matter of fact that the thermo-electromotive force of nickelin against copper is greatly higher than that of the other materials. Standards are always made of copper, and this is of great importance; for the connecting wires in resistance German silver is the least preferable, the alloy which has been almost exclusively used for standard resistances on the Continent; in England an alloy called platinoid is in common use, which does not differ much from German silver. For all alloys time variations were found, which consisted in an increase of resistance for German silver and in a decrease for platinum-silver and platinum-iridium.

Klemenoii further made the important observation that the rate of time variation is influenced in a high degree if the wire is heated to a temperature of 40 to 50 centigrade, in order to determine its coefficient of temperature. He says: Perhaps it would be preferable to expose a newly made standard resistance to a moderate rise of temperature during a longer time in order to terminate more quickly the variations of resistance produced by mechanical stress. Klemenoii did not, however, continue his work in this direction.

One of the duties of the Electro-Technical Laboratory of the Physikalisch-Technische Reichsanstalt, which was founded in 1887, principally by the liberal donation of Werner von Siemens, is to examine the correctness of electrical measuring apparatus, and to make such investigations as tend to improve them.

As to electrical resistances, the determinations of the absolute value of the ohm made some years ago by Kohlrausch and Himstedt have shown to what degree wire resistances can change in the course of time.

It is a matter of fact that Kohlrausch has observed for two German silver standards an increase almost equal in both to the amount of more than one-tenth per cent. in one and three-quarters of a year.

It was up to the present time very tedious to manufacture accurate standard resistances. It was necessary to take wire which had been made a long time before; to wind at the same time a large number of coils which were not to be disturbed for several months; then periodically the value of the resistance was determined and those were chosen for standards which proved to change in the least degree; nevertheless such resistances are not constant at all. During many years changes can be observed, as for instance Mr. Carpenter has shown; this was also proved with a carefully constructed resistance furnished by Carpenter to the Reichsanstalt. Such a resistance must be considered to be in an unstable state; a somewhat larger change of the outer temperature may effect considerable changes, as we have seen it before with a platinum-silver resistance.

Electric traction is being steadily developed in Germany, and is likely, within the next year or two, to make a good showing. There are roads running in Bremen, Halle, Gera, Breslau, Hanover, Dresden and Remscheid, besides the two old Siemens roads at Lichterfelde and Frankfort-Offenbach; and there are roads in course of construction or under contract in Breslau, Chemnitz, Dortmund, Essen, Lubeck, Nuremburg, Plauen, Hamburg, Gotha, Erfurt and Bochum.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:

6 Park Place - New York

CHICAGO:
J. F. CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 75, 120 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

Grounded Railway Circuits.

The return circuits on electric railways, which according to the general practice are grounded circuits of which the tracks are a part, have been the cause of considerable trouble in a number of places because of the electrolytic action of the current on underground pipes, which have frequently been entirely destroyed in this way. In a number of cities this trouble has proved a matter of serious expense, especially where large currents are employed, and it has been seized upon by the deprecators of the "deadly trolley" for the most potent of their arguments.

This difficulty has heretofore been the most valid objection which has ever been raised against electric railway systems, and it cannot be denied that these complaints were in many cases well founded, but at present, thanks to the experience of a number of pioneer roads, this matter is better understood, and the means of providing against any destructive electrolytic action upon the rails or adjacent pipes is easily attained, though not without considerable expense.

The early roads using a rail return were at fault in depending upon the earth to a considerable extent for the return circuit. The error in this assumption is shown by the fact that to-day the ground circuit is not included in the calculations of the capacity of the return circuits. The ground has proved a very uncertain and a very variable quantity in this work as much depends on the character of the soil and the amount of moisture it contains, the latter being a large factor in the electrolytic action on pipes, etc. It appears to be well established that the return should contain sufficient metal to carry the necessary current without depending on the ground, and with a resistance not in excess of that on the overhead system. One of the first essentials in procuring a continuous circuit from the track to the generator is the bonding of the rails. A large number of patterns of rail-bonds have been placed on the market from time to time, but very few of these fully answer the purpose for which they were designed. The average rail on a well built electric road will run from sixty to ninety lbs. in weight, and where many cars are used the entire section of iron in a double-track road is insufficient to carry the current without supplementary ground wires. In such a case the bonding becomes a matter of the utmost importance, and it is evident that a single No. 4 iron wire bond connecting the track joints is entirely inadequate for the purpose. Neglecting the ground, which is not to be depended upon, this construction, which is to be found in a large number of roads, increases the resistance of the return to a very large extent, and is largely accountable for the electrolytic action of which there has been so much complaint. Besides the harm done to other underground systems, the high resistance of the track circuit is felt at the power house, and imposes a proportional additional load on the machinery which in time will largely overbalance the saving in material due to this cheap construction.

In reporting on this subject to the New York Street Railway Convention, Mr. McTighe sums up the requirements for a railway return circuit as follows:

1. Intrinsic resistance low enough to need no help from earth.
2. Utilization, to the utmost practical extent, of the rails as the return conductors.
3. Rail bonds of the heaviest practicable size.
4. Rail bonds of the shortest possible length consistent with due allowance for expansion and vibration.
5. Rail bonds made of a single piece of wire with integral rivets.
6. Rail bonds tightly riveted to the rails through holes freshly reamed immediately before bonding.
7. Rail bonds so placed as to permit convenient inspection.
8. Rail bonds protected against corrosion.
9. A very liberal use of heavy cross bonds from rail to rail direct, and in double track extra heavy cross bonds connecting the two inside rails.
10. An underground main or trunk return from power house to track, and there connected to each line of rails, and low enough in resistance to carry the maximum current with but a nominal drop in potential.

By fulfilling these conditions there is no doubt but that the saving at the power house would be more than sufficient to compensate for the extra cost of track work, and in addition the trouble from electrolysis would be avoided.

In some cases where the difference of potential on underground pipes has been measured, as much as forty or fifty volts difference has been found, and the electrolytic effect of such a current would obviously take but a short time to completely destroy the pipe. The remedy of supplying a larger metallic conductor for the return, and connecting the pipes with the station so as to avoid this action where the current leaves the pipes, has been found to obviate the trouble entirely.

It is therefore well settled that with proper care in construction of the grounded return there would be no foundation for the complaints which are now frequently heard.

……o……

"Electricity" Is Ready.

The present condition of the General Electric Company would excite pity rather than animosity if there should be forthcoming from the Board of Directors an announcement of new executive officers to carry out a radically new policy. Few expressions of pity, however, will be heard until it is an assured fact that the company is to be conducted on new lines, by men who who will confine their attention to the business of the company and allow competitors the same privilege.

For something more than a year ELECTRICITY has waged relentless warfare. We began when the stock was selling above 115, and when a superficial view disclosed nothing of trouble ahead for the General Electric Company; when its officers possessed the esteem of their business associates, and when a word of criticism was looked upon as suicide for any electrical paper.

We had information even at that time upon which we believed a severe attack justifiable, and we have never wavered. The world was then against us; and it is now with us. But ELECTRICITY was just as surely right twelve months ago as it is to-day, when the rottenness and dishonesty of General Electric methods are common gossip and Charles A. Coffin is a discredited man among those who know him best.

Electricity's purpose has been fully accomplished. We have shown the General Electric Company under the mismanagement of Mr. Charles Ausgespielt Coffin to the trade in its true light. We have no animosity towards the company as an abstract thing, nor against the army of men who until recently earned an honest living in the service of the company. Our attack has been aimed at a proposed monopoly, and at corrupt and disgraceful business methods, and against the man who was chiefly responsible for their introduction into this trade.

As to monopoly, or anything approaching it, it is forever passed discussion in the electrical business. But as to the corrupt methods which have indelibly marked the present management of the General Electric Company we have no assurance that they are to be discarded. When we have such assurance, from men in whom the trade has confidence, and when Mr. C. A. Coffin's name is wiped out from all official connection with the company, Electricity will retire from the warpath, and will do all in its power to assist the reorganized company, to restore harmony and good feeling in the trade.

We will cease fighting when the occasion for fighting has been removed.

......o......

Some very poorly informed person has written to ask us, "Who the deuce is Mr. Laf. Heidell, whose portrait you printed this week?" It is safe to say that our questioner has never travelled, does not know of Powers' Block, or even of the city of Rochester. He might as well ask, Who is Tom Ochiltree, or who is Abe Slupsky?

......o......

About six pages of the *Electrical World* last week were devoted to a report of the legal troubles of Messrs. Martin and Wetzler and W. J. Johnston. The matter was undoubtedly of interest to these three gentlemen, but to no one else. Few, however, are surprised to see the pioneer electrical journal prostitute itself by forcing upon its readers this expression of petty personal spite.

......o......

Every day that Mr. C. A. Coffin is allowed to retain his position in the General Electric Company is an extension of time in his preparation for a future career of brigandage in the electrical trade. He should be forced to stand on his own bottom at once.

......o......

The General Electric Company has been killed by the enemies it has made. Those enemies will not be friends under the present management and policy of the company.

......o......

Mr. Joseph P. Ord, Controller of the General Electric Company, is in Chicago. We understand he has gone to pay his respects to Mr. Sunny.

......o......

It is pleasant to call attention to the advertisement in this issue for sixty wiremen, etc. At least one job is going forward.

Monopolies Do Not Monopolize.

Savannah Will Have a Municipal Plant.

Owing to the recent combination of the commercial lighting companies, the city of Savannah, Ga., intends to erect a city plant. A bill will be introduced in the Legislature to secure the necessary authority. Mayor McDonough says:

"If the People's Electric Light Company had remained an independent institution, as it promised, the city would not have found it necessary to enter into the electricity business, because with two companies competing prices for lighting would have been so reasonable that it would have been a useless expenditure to erect another plant. But when the combination with the Brush Company was effected it was seen at once that competition had been throttled."

Electricity has already made sufficient comment on local combines. They can only be successful where they are in perfect harmony with the public and with the city. The cost of lighting should be decreased instead of increased; and any combination that proceeds on a different theory is sure to come to grief.

THOSE HAPPY DAYS.

"So Sad, so Fresh, the Days that Are no More."

(*Not written for "Electricity."*)

Oh! those were happy days, boys, just back in '91,
Before the Thomson-Houston and Edison were one,
Before the lion and the lamb each swallowed up their pride
And laid down in peace together, the lamb on the inside.

The grass upon the Common seemed softer then to all,
God knows that now it's pelted down and hardly grows at all!
And the boys upon the corner would on each Friday night
Blow in their stuff at Ames's—they're over that all right.

Each student had a typewriter, a draughtsman and a pull;
They took their damsels to the dance and after that got full.
Cigarettes were then the thing, and wine was never freer;
They're smoking T. D. pipes now, and drinking Uno beer.

Oh! those were happy days, you bet—when Saturday came round
'Twas off upon the bicycle or to the baseball ground,
And in the eve the Point of Pines would catch them by the thou';
They still go to the Point of Pines—they go to dig clams now.

Common stock was 96, preferred was rather more,
Until the General Electric took possession of the floor.
Stockholders, who were building high, each one as rich as mud,
Have felt their feet slip out from under with a dull and sickening thud.

Oh! those were happy days for clubs; prosperity was high,
And tennis, cricket and baseball, they all were flying high.
And now we're in the consomme, we haven't got a cent,
And even the Scientific Club can hardly pay its rent.

The pay came all in bills then, the envelopes were fat;
It comes in dimes and nickels now, and hard to get at that;
'Twas "quarter ante" in those days, and every man would stay,
Now every man is playing close to keep the wolf away.

Indeed, it's rather rocky now; we hardly get enough
To keep our board bills evened up and make a decent bluff.
Oh! will they ever come again, those happy days of yore?
Those bully days, those flush old days, those days that are no more.

Lynn, Sept. 1, 1893. F. S. H.

A Return to Old Tactics.

The following is a copy of a notice which is being distributed to the patrons of a local lighting company that is controlled from No. 44 Broad street, which needs no comment:

It has come to our notice that some of our *current* customers are using an inferior grade of incandescent lamps requiring a fraction over 5 watts per candle.

This company recommends only the Edison or Thomson-Houston incandescent lamps, which have an efficiency of 3.1 watts per candle. The difference in amount of energy required to operate lamps other than the Edison, or T.-H., is to us a costly and serious matter.

There are reasons of another nature that should cause prudent and careful patrons to discontinue using lamps not licensed by the General Electric Company, owners of the Edison lamp patent, No. 223,898, the United States Circuit Court of Appeals having confirmed the decision of Judge Wallace declaring Mr. Edison the sole inventor of the incandescent lamp. The Edison patent does not expire until January 27, 1897, and the owners are vigorously insisting on their legal and equitable rights in all portions of the country.

Restraining orders were recently issued against the Holland House and Hotel Imperial, New York City. As the owners of the Edison patent insist on an accounting for damages, we believe the wisest course is to discontinue the use of infringing lamps, and purchase none but those marked "Edison" or "Thomson-Houston," which fortunately are the best made. These lamps can be procured at our office, corner of Main and Field streets, at usual price. . . .

Legal Notes.

The Adams Electric Railroad Company's suit against the Lindell Railway Company at St. Louis is about ready for trial. It involves the right to use the propelling mechanism on every electric railroad car in the country. Evidence in the case, which has been accumulating for two years, already fills more than 1,000 printed pages.

The jury in the suit of Kahman Kosrael, of New York, against the New Jersey Traction Company, for $10,000, on account of the killing of his son Harry, at the corner of Springfield avenue and Bedford street, Newark, on May 9, brought in a verdict for the defendant.

Judge Lacombe, of the United States Circuit Court, has appointed Charles Batchelor receiver of the Electrical Development Company of New York. The company was organized in 1890 for the purpose of constructing street railways. It is understood to have practically gone out of business as a construction company. Its assets, consisting of stocks in other companies, have depreciated in value owing to the great shrinkage of values, and its inability to provide money to pay its debts necessitated a receivership.

In the United States Circuit Court, New York, on the 19th ult., Judge Lacombe granted a preliminary injunction restraining the Mount Morris Electric Light Company and the United Electric Light, Heat and Power Company from the further use of the incandescent lights now employed by the two companies in this city. The injunction was granted on the application of the Edison Company. The order is to go into effect after reasonable time has been given the defendants to adapt their fixtures to the use of other lamps which are not open to the objection. The case will be appealed to the Circuit Court of Appeals.

A bill of complaint asking for a receiver for the Citizens' Electric Light and Power Company of Manistee, Mich., has been filed. The complaint alleges that the company has never paid more than running expenses, and is wholly unable to meet its obligations.

The Falls Rivet and Machine Company has filed a mechanics' lien against the Toledo Electric Company for $1,735.

Suit has been begun against the new lighting company in York, Pa., using Westinghouse apparatus, to restrain them from using infringing lamp.

The Cleveland Electrical Manufacturing Company has filed a motion asking the court to order the discontinuance of the business of the Graves Electrical Company, claiming it is being conducted at a loss.

World's Fair Awards.

Following is the list of awards announced up to date. Some of the tests, viz., of wires, storage batteries, incandescent lamps, transformers and a few others, have not yet been completed :

Albert & J. M. Anderson, Boston, Mass.—1. Trolleys. 2. Railway insulators.

Brush Electric Co., Cleveland, Ohio—1. Direct current dynamos for series arc lighting. 2. Direct current dynamos for series arc lighting, coupled to engine, 125-2,000 C. P. lamps. 3. Alternating current dynamos, constant potential, 36-150 K.W. 4. Arc circuit switchboard. 5. Direct current dynamos, constant potential, 20-100 K.W. 6. Arc lamps, all types.

Bryant Electric Co., Bridgeport, Conn.—Snap switches.

W. R. Brixey, New York—Underground, aeria and submarine telegraph and telephone cables.

J. H. Bunnell & Co., New York—1. Standard dry batteries. 2. Telegraphic apparatus.

C. & C. Electric Motor Co., New York—1. Direct current motors, constant potential, 3-50 H. P. 2. Electric motor, fan and blower combination.

Cutter Mfg. Co., Philadelphia, Pa.—Pushsw es for electric lights.

Commercial Cable Co., New York—1. Ocean telegraphic apparatus operating through Muirhead's artificial resistances. 2. Cuttriss improved cable telegraph apparatus.

Crane Electric Co., Chicago, Ill. — Electric passenger elevator complete.

Carpenter Enamel Rheostat Co., Bridgeport, Conn.—Rheostats.

Copenhagen Fire Alarm Co., Chicago—Automatic fire alarm.

George Cutter, Chicago, Ill.—Lamp supporting pulley.

Electrical Forging Co., Boston, Mass.—Electric heating and welding apparatus.

Electric Heat Alarm Co., Boston, Mass.—Thermostat for automatic fire, hot journal and hot grain alarms.

Electrical Conduit Co., New York—Underground conduit for electrical wires.

Electric Launch and Navigation Co., New York —Electric launches.

Eddy Electric Mfg. Co., Windsor, Conn.—Direct current motors, constant potential.

Excelsior Electric Co., New York—1. Arc lamps series circuits. 2. Direct current dynamos for series arc lighting.

Elektron Mfg. Co., Springfield, Mass—1. Direct current motors, const't potential, multipolar, slow speed. 2. Automatic motor starter.

Electric Selector and Signal Co., New York—Electrical system for locking and unlocking.

Edison Mfg. Co., New York—Edison-LaLande primary battery.

Eureka Tempered Copper Co., North East, Pa.—Tempered copper for use in electrical construction.

Fort Wayne Electric Co., Fort Wayne, Ind.—1. Direct current "Wood" dynamo for series arc lighting. 2. Alternating current "Wood" dynamo, constant potential, compound wound, 150 K. W. 3. Arc lamp for constant current.

I. P. Frink, New York—Screen reflectors for incandescent lamps.

General Electric Co., New York—1. Electric locomotives for factory and switch service. 2. Electric elevated railway system. 3. Long distance power transmission, plant in operation, tri-phase. 4. Arc lamps for direct current series circuits. 5. Searchlights and focusing lamps. 6. Transformers 250-125,000 watts. 7. Engine dynamos. 8. Automatic overload switch. 9. Electrically illuminated fountains. 10. Thomson eccentric coil ammeters and voltmeters for alternating currents. 11. Pumping machinery driven by electric motor. 12. Electrically driven rock working machinery. 13. Mine locomotive. 14. Haskins astatic ammeter. 15. Arc lamps for constant potential circuits direct and alternating (Knowles). 16. Jaw switches, fuses, sockets and branch blocks. 17. Direct current dynamos for series arc lighting. 18. Alternating current dynamos for series arc lighting. Alternating current dynamos, constant potential, 30-300 K. W. 19. System of street railway service. 20. Direct current dynamos, constant potential (direct connected excepted), and direct current shunt wound motors, constant potential. 21. Edison feeder system for distribution of electricity. 22. Slate switchboard for arc light circuits. 23. Ventilating set, portable, Government standard. 24. Historical apparatus. 25. Edison three-wire system for distribution of electrical energy. 26. Exhibit of incandescent lamps all styles, ½ to 250 C. P. 27. Underground system complete in all details. 28. Hoisting apparatus driven by electric motors. 29. Integrating wattmeter.

The E. S. Greeley & Co., New York—1. Testing instruments. 2. Extra dry battery. 3. Telegraph apparatus.

Gamewell Fire Alarm Telegraph Co., New York—Automatic fire alarm telegraph system.

General Incandescent Arc Lamp Co., New York —Arc lamps for constant potential circuits.

Hart & Hegeman Mfg. Co., Hartford, Conn.—Snap switches.

Helios Electric Co., Philadelphia, Pa. — Arc lamps for alternating current.

The Hanson Battery Co., Washington, D. C.—Primary batteries.

Interior Conduit and Insulation Co., New York—1. System of interior insulating conduits. 2. Snap switches.

Jenny Electric Motor Co., Indianapolis, Ind.—Direct current dynamos and motors, constant potential.

H. W. Johns Mfg. Co., New York—Vulcabeston and molded mica insulating material worked into all kinds of insulations.

LeClanche Battery Co., New York—LeClanche batteries, especially the "Vole" and "Cylinder" cells.

Mather Electric Co., Manchester, Conn.—Direct current dynamo, constant potential, 500 volts.

McIntosh Battery and Optical Co., Chicago, Ill. —Electro-medical, dental and surgical apparatus.

National Carbon Co., Cleveland, Ohio—Carbons for arc lamps.

Nutting Electric Mfg. Co., Chicago—Nutting arc lamps.

Otis Bros., New York—1. Electric pump. 2. Electric motor and controlling devices for elevator and hoisting service.

H. T. Paiste, Philadelphia, Pa.—Snap switches.

Police and Signal Co., Chicago—System of police patrol telegraph.

Phœnix Glass Co., Chicago—Electric and glass globes and shades cut, etched and colored.

Queen & Co., Philadelphia, Pa.—1. Electrometer (Ryan). 2. Galvanometers. 3. Testing sets and resistances. 4. Portable medical induction apparatus for physicians' use. 5. Commercial ammeters and voltmeters.

J. A. Roebling's Sons Co., Trenton, N. J.—Bare copper and trolley wire.

F. A. Ringler & Co., New York—Half tone photo-electro type, steel faced.

Standard Electric Co., Chicago—1. Arc lamps for direct current series circuits. 2. Direct current dynamos for series arc lighting.

Stevenson-Hoggson Electric Co., St. Louis, Mo. —Automatic electric time stamp.

Sperry Electric Railway Co., Cleveland, Ohio—Electric railway system.

Short Electric Railway Co., Cleveland, Ohio—Short electric railway system.

Self-Winding Clock Co., New York—Special application of an iron-clad solenoid magnet.

Thomson Electric Welding Co., Boston, Mass.—Apparatus for electric welding and forging.

Union Electric Works, Chicago—Primary battery.

J. C. Vetter & Co., New York—1. Incandescent current adapter. 2. Dry LeClanche battery.

Western Electric Co., Chicago—1. Columbian street lamp post. 2. Telegraph apparatus. 3. Telephone cables, Paterson. 4. Annunciators and signalling apparatus. 5. Multiple switchboard for telephone service. 6. Direct current dynamos for series arc lighting. 7. Application of electric lights for the production of scenic effects in theatres and for the decoration of rooms, etc. 8. Arc lamps various styles for series circuits. 9. Arc lamps for constant potential circuits. 10. Direct current dynamos and motors, constant potential.

Waite & Bartlett Mfg. Co., New York—1. Holtz induction machines in air-tight case with 6 40 inch revolving plates. 2. Special faradic apparatus for varying the tension and strength of current (Engleman'apparatus).

Washington Carbon Co., Pittsburg, Pa.—Carbons for arc lamps, batteries and dynamos, and motor brushes.

Wm. Wallace, Ansonia, Conn.—Historical electric light exhibit.

Walworth Mfg. Co.—Poles for trolleys and arc lamps.

S. S. White Dental Mfg. Co., Philadelphia, Pa. —Acid gravity batteries, "Partz."

Westinghouse Electric and Mfg. Co., Pittsburg, Pa.—1. Engine dynamos. 2. Transformers, 250-12,500 K. W. 3. Direct current dynamos and motors, constant potential, bipolar and multipolar (except direct connected dynamos). 4. Alternating current dynamos, constant potential, 750 K. W. 5. Electric street railway system. 6. Alternating current dynamos for series arc lighting. 7. Long distance power transmission, plant in operation. 8. Two-phase alternating current motors (Tesla). 9. Incandescent system of street lighting. 10. Switches. 11. Complete switchboard for controlling 17 dynamos and 40 currents. 12. Lightning arresters.

Weston Electrical Instrument Company, Newark, N. J.—1. Alternating current instruments, including wattmeters. 2. Standard resistance and bridges. 3. Electrical measuring instruments for physicians' use. 4. Switchboard instruments. 5. Direct current ammeters and voltmeters, standard and portable.

Western Union Telegraph Co., New York—Instruments used in quadruplex telegraph, latest design.

Zucker & Leavett Chemical Co., New York—Collection of chemicals and appliances] for electroplating.

GERMAN.

Prof. Aron, Berlin—Electric meters.

J. Berliner, Hanover—Universal transmitter, long distance.

Geo. Carette & Co., Nuremburg—Optical, physical and mechanical instruments and toys.

Dr. Edelmann, Munich—Electro-medical apparatus

Felton & Guilleaume, Muhlhausen on Rhine—1. Electric cables with special armor. 2. Electric cables.

Gehmelzen, Nuremburg—Carbons for arc light.

Hartmann & Braun, Frankfort—1. Differential arc lamps. 2. Galvanometers. 3. Electrical measuring instruments, including instruments of precision. 4. Photometer, large universal. 5. Apparatus for testing iron and steel with respect to magnetic permeability. 6. Reading telescopes, mirrors and scales. 7. Portable measuring apparatus used in laying cable.

W. A. Hirshman, Berlin—Electro-medical apparatus.

Imperial German Postal Telegraph Dept., Berlin—1. Maps and drawings showing system of Government telegraph lines using armored underground cables. 2. Telegraphic apparatus of the German telegraph service.

Korting & Matthissen, Leipsig—Arc lamps for constant potential circuits.

H. Schomburg & Sons, Berlin—1. Insulators and insulating material. 2. Dry batteries.

Schuckert & Co., Nuremburg—1. Searchlights with parabolic glass mirrors. 2. Annunciators for vessels. 3. Arc lamps for constant potential circuits.

Siemens & Halske, Berlin, 1. Arc lamps for constant potential circuits. 2. Direct current dynamos, constant potential, 750 K. W. 3. Historical apparatus.

Schmidt & Haench, Berlin—Lummer-Brodham photometer with accessories.

J. Zacharias, Berlin—Dry batteries.

TURKEY.

Imperial Ottoman Government—Telegraphic apparatus.

GREAT BRITAIN.

British Government Postal Telegraph Dept.—1. Modern telegraph apparatus in operation. 2. Historical telegraph apparatus.

Corporation of Birmingham—Original Woolwich dynamo.

General Electric Co., Ltd., London—H. I. switches and other incandescent house fittings.

James White, Glasgow—Electro-magnetic balances, Kelvin.

AUSTRIA.

F. Hardtmuth & Co., Vienna—Carbons for arc lamps, etc.

RUSSIA.

Imperial Russian State Paper Manufactory, St. Petersburg—Collection of electrotypes.

Imperial Artillery Arsenal, St. Petersburg—Electrical registering attachment for testing machine (Prince Gagarian.)

ITALY.

Prof. Galileo Ferraris, Turin—Historical alternating current motors.

JAPAN.

Imperial University, Tokio—1. Seismographs and accessory apparatus. 2. Model of an earthquake.
Department of Engineering, Imperial University, Tokio—Automatic electric current recorder.

BRAZIL.

Directoria General dos Telegraphos, Rio de Janeiro—Telegraphic apparatus.

Bids Wanted.

Proposals will be received at the office of the village clerk, Plain City, Ohio, for the construction of a complete system of water-works and electric light plants. Specifications may be obtained from the engineer, Frank Snyder, Columbus, Ohio.

The Eddy Electrical and Manufacturing Company, at Windsor, Conn., which was working on reduced time in August, has been running full time for the past two weeks, and with a full complement of hands.

General News.

What is Going on in the Electrical World.

Baltimore.—The Lombard street division of the City and Suburban Railway is now operated by electricity.

Waterbury, Conn.—The Traction Company has received permission from the council to use electricity as a motive power on its lines.

McKeesport, Pa. — East McKeesport will shortly be lighted from the Wilmerding Light Company's plant. The wires are already in place.

Brooklyn, N. Y.—The State Railroad Commissioners have granted the Brooklyn City Railway permission to change from horse power to electricity.

Westchester, N. Y.—The Bronx Company of West Farms is about to put in a plant for the lighting of this town for which that company has a contract.

Hoboken, N. J.—The North Hudson County Railway Company have petitioned the Hoboken Council for permission to equip all their city lines with the trolley.

Smyrna, Del.—Charles E. White, of Philadelphia, has been awarded the contract for the erection of a complete electric light plant in this town to cost $9,430.

Windsor Locks, Conn.—The Electric Lighting Company of this town is about to put in a 150 horse power engine. The capacity of the dynamos will be increased from 750 to 1,200 lights each.

Detroit, Mich.—The manager of the Commercial Electric Company states that the chattel mortgage on the company's stock, recently effected, will not result in a suspension of the business.

Oakland, Cal.—W. E. and H. W. Meek and others have asked for permission to construct and operate a street railroad on the county road leading from Oakland to San Leandro, the motive power to be electricity.

Cincinnati.—The diminution of the smoke nuisance in this city is attributed in a large measure to the use of the new smokeless coal and the substitution of electricity for steam power in many small manufactories.

Leavenworth, Kan.—Newman Erb, receiver for the Leavenworth Electric Railway Company, intends, it is stated, as soon as the affairs of the electric company are settled, to equip the dummy and horse cars lines here with electricity.

Belair, Md.—An electric road between this place and Havre de Grace is under consideration, and the Hughes & Rigby Company, of Baltimore, who have the contract for lighting Belair, are making investigations in regard to the project.

Washington. — Telephone communication from the shore to vessels near shore by means of a cable has been demonstrated by the Light House Board to be practicable, and this new method will be put into operation as soon as funds are available for the purpose.

Middletown, N. Y.—The Eureka Electrical Company of New York has secured the contract for putting additional wire in the State Hospital and its new buildings, together with the cottages and barns. An electric cooking range is also to be added to the kitchen.

San Francisco.—The San Francisco and San Mateo Electric Railroad has arranged to carry funerals to the cemeteries in San Mateo County. On the 17th of September the first funeral was satisfactorily conducted over the road. The train was made up of the funeral car and two coaches for the mourners.

Buffalo, N. Y.—Work on the Buffalo, North Tonawanda and Sanborn Electric Railroad is expected to begin this week. The officers of the company are : L. F. W. Arend, president; Lewis T. Paine, of Tonawanda, vice-president; Lee R. Sanborn, secretary; Edward G. Reisterer, of Tonawanda, treasurer.

Albany, N. Y.—Electrical freight cars are about to be put on the line between this city and Troy. The cars are about the size of the ordinary passenger cars and resemble the baggage cars of steam railroads. Three of these cars already received here were built by the J. Y. Brill Car Company of Philadelphia.

Kingston, Ont.—A few days ago the electric railway on Princess street was opened for traffic to the delight of the citizens, who, as the first car was put in motion, ran up and down the streets cheering. A young lady christened the road by breaking a bottle of champagne over the dashboard of the car as it began to move.

Youngstown, Ohio. —The city commissioners and others of the committee appointed to consider the applications of the Youngstown Park and Falls Company and the Youngstown and Canfield Electric Railway Company for franchises have decided, after consultation, to advertise for proposals for electric railways over the routes.

Beverly, Mass.—The Beverly selectmen have granted the Lynn and Boston Street Railway Company an extension of the time allowed to equip their line from Gloucester crossing to the Wenham line with electricity from October 1. 1893. to July 1, 1894. The Danvers and Beverly line will also be equipped in the spring so as to be put to use next summer.

Kingston, N.Y.--The residents of Shanhaken, Lexington and Westkill are considering the advisability of building an electric road from Shanhaken through the Westkill Valley to Lexington, fourteen miles. The question has not yet been decided but there are a number of men in the three places who have signified their willingness to take stock in the proposed road.

Alton, Ill.—The proposed electric line to North Alton is being pushed by the new electric company, of which J. F. Porter is vice-president. Mr. Porter has advertised for sale seventy $1,000 six per cent. interest bearing bonds of the proposed road, with the St. Louis Trust Company as surety and trustee. The stock is presented to the citizens of Alton as an excellent investment.

Charlotte, N. C.—The *Observer* of a recent date says : "Mr. Cutler, of the General Electric Company of Boston, is in the city, and it is supposed that he is still considering the transmission of power from the Catawba River to Charlotte. It would be a big thing for the city if five to ten thousand horse-power could be transmitted here for sale in the shape of electric current or power."

Butte City, Mont.—The annual statement of the Northwest General Electric Company, whose Montana headquarters are at Helena, shows that the capital stock September 1 was $1,500.000, of which $856,500 had been paid in money and $643,500 in franchises, merchandise and accounts. The assets of the company are $3,234,227.53, in which is included the capital stock of $1,500,000 and a surplus and undivided profits amounting to $197,171.11.

Adrian, Mich.—The company that proposes to construct and operate an electric railway between here and Ypsilanti has purchased the electric line in this city and also controls the line connecting Ypsilanti and Ann Arbor, two important links in the proposed line, which is to connect Adrian, Tecumseh, Clinton, Macon, Saline, Ann Arbor and Ypsilanti, and cover sixty-two miles in length. To complete the line it will be necessary to build forty-two miles of new track. Samuel D. Nesmith, of Adrian, is the principal promoter of the proposed road.

Toledo, Ohio.—A number of Eastern capitalists are understood to have put up the money to secure the right of way for the projected electric railway between Toledo and Detroit. Toledo and Detroit capitalists are also taking an active part in the scheme, which seems now in a fair way to be carried out successfully. A stock company is to be organized with a capital of $1,000,000, one-fourth of which is to be paid in cash. The equipment of the line will be of the most approved kind, the motors to be of 100 horse power and the speed not less than thirty miles an hour. Passengers, express matter, and light freight will be carried on the trains. The local men interested in the enterprise are L. K. Parks, J. H. Ainsworth, Ellery Eaton and J. H. Dawson. H. J. Warner, of New York City, represents the Eastern capitalists.

Philadelphia. — "Rapid progress," says the *Ledger*, "is being made in many parts of the city in the construction of the new trolley roads. The work attracts a large amount of attention, especially in the centre of the city, where in many places the workmen are busy night and day laying conduits and putting down the heavy girder rails which are necessary to carry the electric cars. No expense is being spared by either of the two great companies, the Traction and the People's Traction, and each boasts and expects to have the finest electric railway plant in the world when the work is completed. As the Traction Company's lines are being erected on the Westinghouse system and the People's lines on that of the General Electric Company, the two great rivals in electric construction, the outcome is regarded with great interest by all who are conversant with electrical matters."

New Orleans.—The articles of agreement between the New Orleans Traction Company, limited, and the New Orleans City and Lake Railroad Company have been printed. Among other stipulations the Traction Company agrees to furnish the City and Lake Railroad Company at all times during the continuance of the contract an electric current of proper and sufficient electromotive force to supply light and motor power for the propulsion of all of their cars at the maximum rate of speed allowed, and at all times to keep the motors, cars and electrical and lighting apparatus in the said cars and connected with the operation of the said trolley system in good order and condition, and to make all renewals and repairs thereto made necessary by accident of wear and tear, and to keep said cars and electrical apparatus at all times in an efficient condition.

Boston Notes.

Though it is less than two years since the New England Telephone and Telegraph Company equipped and began to use their extensive exchange in the Bell Telephone Building, Milk street, the growth of the business has been such that it has become necessary to establish another Exchange in the western part of the city. This will be known as the "Haymarket" district. A block of property on Chardon street was secured some time ago and plans for the new Exchange have been completed. The building will be of four stories, with high basement. In the basement will be a workshop, linemen's room and heating apparatus. The first floor will contain a distributing department and store rooms. On the second floor will be a parlor in front, wardrobes, toilet and bath rooms in the rear. On the third and fourth floors will be the operating rooms for the new district.

For the month ending September 20 the total output of instruments by the Bell Telephone Company showed a net decrease of 11,932.

The Boston Electric Light Company, which does the city lighting, has declared a quarterly dividend of 2 per cent. payable October 14.

The citizens of Melrose, Mass., complain that they are being charged exorbitant rates for electricity by the Malden Electric Light Company which supplies current to its neighbors. These complaints have been embodied in a petition to the State Board of Gas and Electric Commissioners, who will give a public hearing on the subject in Melrose, October 12, when a lively discussion is expected.

October 9 is the date appointed for hearing the case of the Mather Electric Company vs. the Thomson-Houston Electric Company. This dispute arose out of what was considered by the plaintiff company to be unwarrantable interference with their business by the defendant when the matter of awarding the contract for lighting the State House Extension Building was under discussion. It is expected that this trial will settle the question as to the legality or illegality of the General Electric Company as a Trust. Should the General Electric Company be in existence at the above date, the trial is likely to prove, if anything, of even greater National importance than the now famous Beacon lamp case, which was tried last February.

Supplementary to our item in last week's issue, pertaining to the Thomson Scientific Club at Lynn, we may state that an adjourned meeting of members was held last Tuesday evening, to take steps for either winding up its affairs or continuing its existence on a more proscribed scale. After a long discussion, there was consensus of feeling that an effort should be made to continue under more economical management. It is sincerely to be hoped that an institution which has proved of inestimable social and intellectual value to its members may not have to be abandoned finally, for such institutions are none too plentiful, and it would be a distinct loss to the enterprising and talented young men identified with the General Electric Company. Our word to the executive board of the club is one of encouragement in their effort to preserve the institution intact until "the good time coming" gets here, as we feel sure it must ere long.

A CORNER IN THE SHOW ROOM OF THE HORN, BRANNEN & FORSYTH COMPANY.

Citizens residing in certain parts of Somerville are petitioning the West End Railway Company to extend its electric system in certain directions at once, so as to have additional cars running by January 1, 1894. They are also trying to secure a 5 cent transfer check on the different routes in the city.

Beginning with Monday a general reduction of wages will take place among the employees of the General Electric Company. About 300 men at the Lynn factories will be affected by the change. The salaries amounting to from $3,000 to $5,000 per annum will be reduced 10 per cent., and those of from $1.000 to $3.000 per annum will be reduced 5 per cent. No reduction will be made in the salaries of clerks and others who receive less than $1.000 per annum. These reductions will apply to men employed at Schenectady and all other works of the company.

The American Railway Improvement Company of this city has begun work on the electric road that is to connect Randolph and Braintree, Mass. This section will form the connecting link between the Brockton and Quincy systems, and unite the shoe city with Boston. They are twenty-two miles apart; the full length of the new section with branches will be fourteen miles.

Reports have been rife the past week as to what really is to be the outcome of the rapidly accumulating financial and managerial troubles that the General Electric Company is suffering from. Almost daily encouraging reports appear in some of the morning or evening newspapers as to the growing improvement in the company's affairs; but of late so much "bluff" of this kind has been thus retailed that no one believes these oft appearing paragraphs, and it were well that the fertile brain from which they emanate should appreciate this fact and act on the old but trite saying that "silence is golden." Public confidence, if there is a spark of it left, which is doubtful, might then in time be to some extent restored. Even the latest movement inaugurated for "raising the wind" wherewith to ward off the impending crash, under the title of the Electric Traction and Illuminating Company, which for the trifling bonus of $4,500,000 undertook to take care of $9,000,000 of assets, is now being discredited. Notwithstanding that the report has been published that 40 per cent. of the entire amount subscribed for has been actually received, financial circles are doubtful if that be so. The latest report is that this syndicate is willing to assume entire management of the company's affairs in the hope of being able to straighten them out. Should events prove the truth of that report, a pertinent question that will arise will be, how will the thousands of small stockholders fare at the hands of this syndicate of millionaires. The sudden death of Mr. F. L. Ames has without doubt raised a formidable obstacle in the way of perfecting a deal which many have regarded as "a consummation devoutly to be wished" in view of the tottering aspect of General Electric Company's affairs.

Where Electroliers are Made.

The Factory of the Horn, Brannen & Forsyth Company.

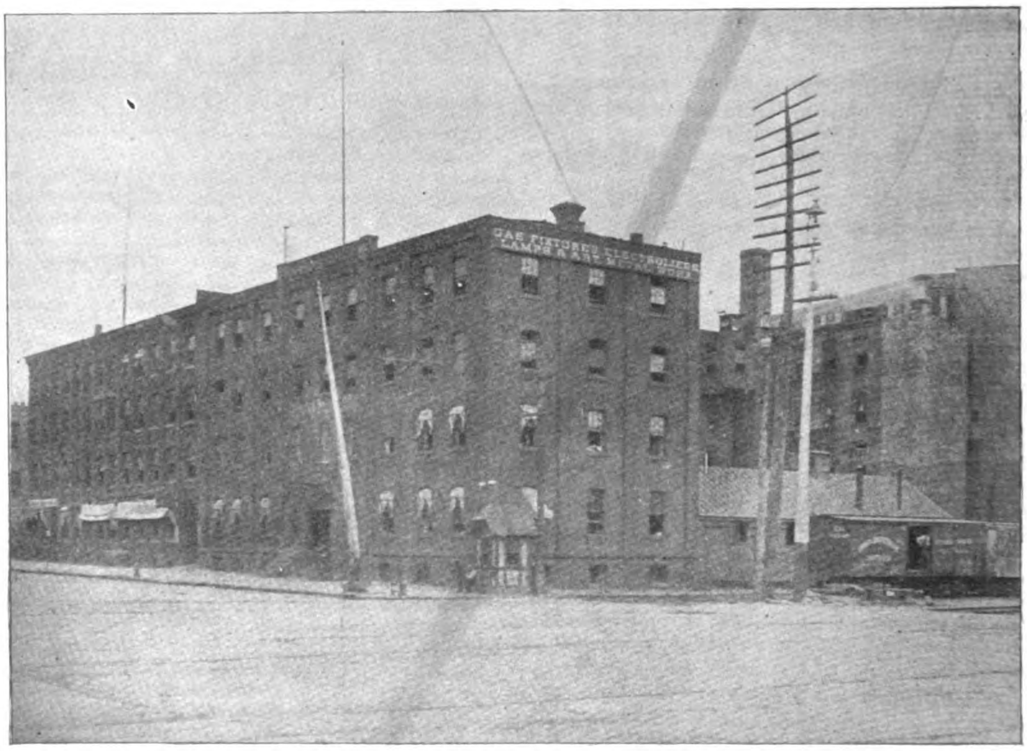
The city of Philadelphia contains one of the largest companies engaged in the manufacture of electric light fixtures, whose factory, situated on the corner of Broad street and Pennsylvania avenue, is illustrated below. In this building every operation in the manufacture of electric light and gas fixtures, from the foundry work to finishing and polishing, is carried on.

The building is a spacious one of four stories and occupies a ground space of 148 feet front by 90 feet. The first floor is occupied by the general offices of the company and the show rooms, a corner of which is illustrated herewith, and the remainder of the ground floor is devoted to a foundry in which all the brass castings used in the works are turned out.

The second story is used for some of the most interesting parts of the work and is divided into a number of different shops. Here the modeling and designing of the fixtures is carried on, as well as the dipping, plating, buffing and finishing of the fancy brass, bronze and other ornamental metal parts.

The third floor of the factory is devoted to laquering, fitting and finishing rooms and a general stock room; the upper floor contains the machine shops, where spinning and turning are done, and on this floor another department of this company's business, clock making, is also carried on. These shops, when working full, operate about 250 hands, but at present, being the usual dull season for this work, only 175 employees are required.

The class of goods manufactured here present too bewildering an assortment of sizes, shapes and patterns to fall within the scope of a brief description, but the elegance of the designs and finish of these fixtures has been increased year by year until to-day many of them are well entitled to rank as works of art.



FACTORY OF THE HORN, BRANNEN & FORSYTH COMPANY.

Coney Island Conduit Road Tests.

The following figures are given by Mr. E. W. Stevenson as the result of a test made by him on the electrical conduit road at Coney Island, which was described in a former issue of ELECTRICITY:

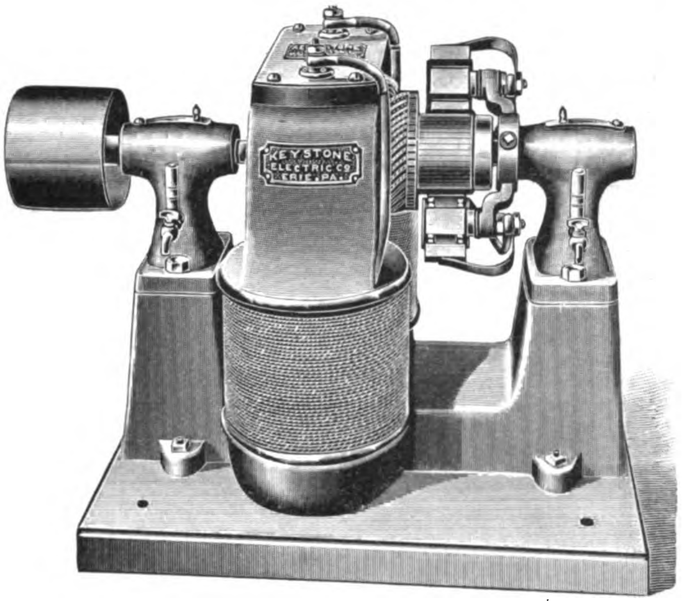
The insulation resistance of the whole line when the car is not in circuit equals 61,500 ohms.

The insulation resistance of line, with shoe of car and adjacent switch-boxes in contact with shoe submerged in water, equals 380 ohms.

E. M. F. of power circuit equals 353 volts; 353–380 equals .926 amp. loss.

Seventy-five feet of conduit was pumped up full of water previous to test.

With Weston ammeter the reading was hardly discernible.



KEYSTONE ELECTRIC CO ERIE, PA.

THE KEYSTONE DYNAMO.

The loss on boxes tested by Weston voltmeter showed nothing.

The resistance test was made with a Thomson tripod galvanometer and by comparison with standard resistances.

From the above figures the following result is arrived at:

As seventy-five feet of the conduit was submerged, this would include twelve boxes. Therefore it is safe to assume that the loss was only on those boxes. Several of the dry boxes showed no leakage.

Then, as the loss on the circuit, with boxes all open—that is, electrically—was .0058 ampere, equaling .0027 H. P., the loss on each box equals 1-12, which amounts to .000483 ampere, and which equals .000223 H. P. It therefore would take 4,484 boxes entirely submerged to give a loss of 2.113 amperes or 1 H. P., and as the boxes are six feet apart this equals 5.092 miles.

The car standing with the shoe entirely submerged and the two adjacent boxes with switches turned on showed a loss of .926 ampere, equaling .438 H. P. And as the car takes about 12 amperes, equal to 5.68 H. P. on ordinary track, this shows that it loses 7.69 per cent of its power when so placed; or, expressed differently, thirteen cars placed in the same condition would lose about the same amount of power which it takes to drive one car.

A progressive brick manufacturer in Auburn, Me., has arranged an electric motor to do the work of horses in grinding. In all yards where horses are used it is an established fact that one of the greatest troubles experienced in the windlass and treadmill is the rapid decline of the horses, as the strain upon their shoulders is so great that they succumb in a very short time. Other New England manufacturers are adopting the use of electricity in their plants, and with such excellent results as to premise the opinion that it will soon become universal.

Keystone Dynamos and Motors.

The general design of the dynamos of the Keystone Electric Company is shown in the accompanying illustration. They are built both for lighting and power, and are either shunt or compound wound, as the case requires. The Standard Constant Potential Dynamos are wound for 110, 220 and 500 volts. They also build machines of special voltage to order. A special winding is used where close regulation is required under great variations of load. Shunt dynamos are provided with hand regulator to adjust great changes of load. A substantial switch is used to open main circuit, also the field and armature connections, all of which are substantially made and in convenient position to operate. The commutator is of hard copper, made in a most substantial manner, insulated with mica, and will last for years with ordinary care. A high insulation test is made on all machines before leaving the factory, also a working test under full load. These are kept on file.

The mechanical construction is of the best throughout. skilled mechanics being employed, with the most improved machine tools, and the work is under the supervision of competent mechanical and electrical engineers. The armatures of these dynamos are wound to carry a greater volume of current than the nominal capacity of machines require, making them safe for the given load. Both dynamos and motors of this make have high efficiency. great solidity and strength and perfect regulation.

KEYSTONE ELEVATOR MOTOR.

Those who are paying for power to operate elevators, whether water or steam, would do well to look into the merits of the Keystone elevator motor.

With hydraulic elevators, where water is taken by measure, even at the lowest prices given, the system is expensive, as it requires the same number of gallons to raise 100 pounds as it would to raise a full load, while with the electric motor the amount of energy consumed is in proportion to the load to be raised, and where current can be paid for by measure through meter the cost of operating an elevator is much less than by water.

The Keystone Motor is a reversing motor which will run in either direction to raise or lower platform, and stops when elevator stops. This reduces the cost of power to the actual working time of elevator platform, and is in most cases 50 per cent. less than by either water or steam.

The company are furnishing these motors for passenger service where speed of platform is as high as 300 feet per minute. They have made a special study of this service, and are prepared to furnish, under a satisfactory guarantee, elevator motors.

A New Apparatus for Projection.

BY OSCAR KNIPE.

Although the advantages of screen projection for illustration of lectures and scientific experiments have been generally admitted, and the projector has been introduced in very many class rooms, the full extent of its usefulness for scientific projection could not until recently be realized, partly because the oxy-hydrogen light is not powerful enough, and the electric arc lamps were not perfect enough to obtain a steady light and satisfactory results. Within the last two years, however, a new style of electric arc lamp has appeared, and one of its principal recommendations is that it is adapted to a low potential [that is, the incandescent current], insuring perfect immunity from electric shock and an absolutely steady and continuous light. Every expert will be delighted to learn that he can let his electric light take care of itself so that he may devote all his attention to his lecture or experiments, as the case may be.

The object of this paper is to describe a new apparatus, the Paragon, Fig. 1, which the writer has employed for nearly two years in projection with the microscope, the polariscope, etc., with unparalleled success, so that professors in some of the foremost colleges highly commended the exhibition and declared it superior to anything seen by them.

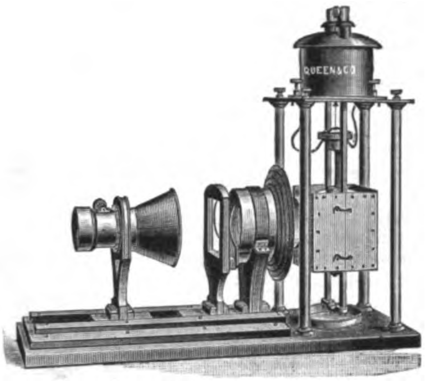


FIG. 1.

This new projector differs essentially from all former apparatus in construction. Advantage has been taken of the style of arc lamp to completely separate the optical system from the light. Here we have a complete slide base with a number of carriers disposed upon it similar to an optical bench, and by this arrangement the various lenses or other accessories can be located as desired and the whole set can be set at the proper distance from the light without interfering with its adjustment. A set of three differential condensing lenses. mounted in cells separately, enable the operator to select the most suitable for any special experiment to obtain the best results in illumination as well as in definition; this is not possible with the old style combined double or triple condenser fixed in the lantern.

For the projection of scenes and diagrams the Paragon is furnished with a special achromatic objective, supplemented with the patent multifocal lens; this lens placed behind the objective diminishes its magnifying power without interfering with its definition, so that the distance from the screen can be doubled and yet produce a picture of half the size that the objective alone would give.

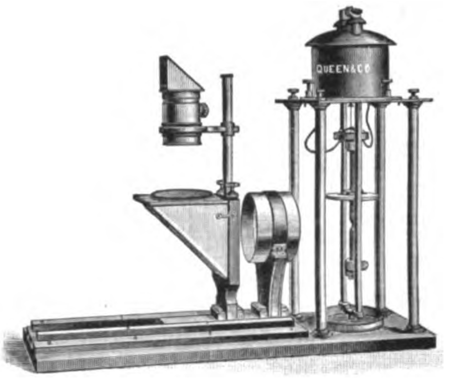

FIG. 2.

This constitutes the Paragon Projector for illustrating lectures on history, geography, etc., by views and diagrams; but its principal distinction consists in the accessories, and here we discover at once the advantages of the optical bench.

1. The vertical prism [Fig. 2] either attached or separate from the lantern has always been troublesome for proper adjustment, but no difficulty nor delay is experienced with the Paragon; here it is perfectly central and a correct performance can be effected in a moment. For the display of magnetic curves by iron filings, cohesion figures in the horizontal tank, etc., this apparatus is indispensable.

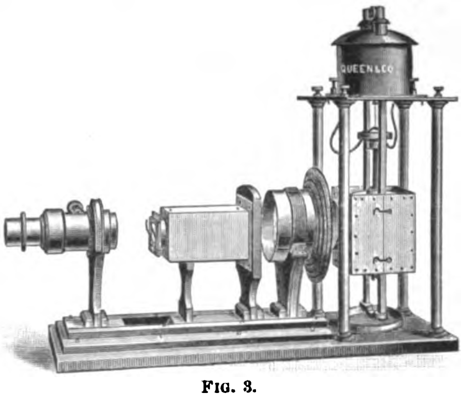

FIG. 3.

2. The polariscope [Fig. 3] is composed of a pile of thin

glass plates for polarizer mounted on a slide stand and provided with an object-holder which can be rotated. It is easily adjusted to the light, so that the refracted ray enters the analyzer and crosses at its centre. If desired, a silvered mirror can be attached over the pile to intercept the reflected ray, which may then be projected simultaneously with the refracted one and thus produce two images.

The analyzer is a 20 m. Nicol prism mounted on a rotating cell which is fitted in the objective. A complete disc of polarized light can be projected, alternating light and dark with the rotary motion of the analyzer. Among the objects suitable for this instrument may be named the following: Geometrical designs of mica and calcite, chilled glass shapes [verre trempe], chemical preparations, crystallization of acids while in progress.

3. The polariscope is also supplemented by a combination of converging and disperging lenses for the purpose of exhibiting the colored rings and crosses in crystals in general; for special scientific investigation in crystallography, the necessary graduated circles and verniers, goniometer, etc., can easily be added to complete it.

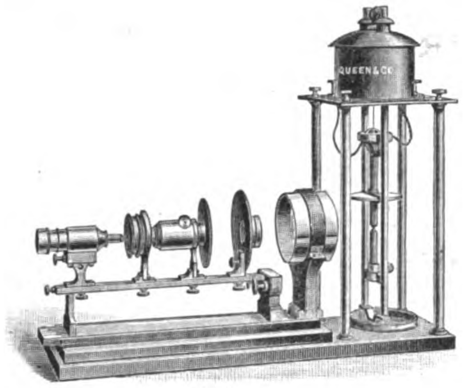

FIG. 4.

4. The projection microscope [Fig. 4]. The distinguishing feature of this is found in the application of an achromatic negative lens to convert the converging rays coming through the condensing lens into a cylinder passing to the secondary condenser; these are provided with rack and pinion, so that the illumination of the object can be adjusted with great nicety. Not only is the silvery whiteness of the arc light a great advantage, but as the radiant is comparatively a point the definition given by a good objective is superb. Abundant light is at hand to obtain a power of 1,000 to 3,000 diameters with perfect definition; a flea may be enlarged to 15 feet in length.

The Cutler-Hammer Manufacturing Company.

Messrs. Cutler & Hammer, of 313 South Canal street, Chicago, the well known dealers in superior electrical apparatus, in order to supply the demand for their high-grade specialties and electrical contract work have found it necessary to greatly increase their facilities and have purchased the factory of the Chicago Electric Manufacturing Company, 241 and 247 South Jefferson street, which they will operate as the Cutler-Hammer Manufacturing Company. Their present facilities are therefore unequalled by any factory in Chicago, while their long experience and the skilled workmen they employ enable them to produce the highest grade of special electrical apparatus, thereby sustaining their well-earned reputation for first-class and intelligent electrical work.

The firm will continue to carry a complete stock of their popular C. & H. Snap Knife Switch and Automatic Motor Starter, and are prepared to furnish on short notice any apparatus in their line.

Any inquiry made of them in reference to these goods will receive prompt and cheerful attention.

COMMERCIAL PARAGRAPHS.

The Electro-Chemical and Specialty Company of New York have lately placed on the market a Battery Compound which is worthy of investigation. It is said to be both cheaper and better than sal ammoniac.

The Keystone Electric Company of Erie are now comfortably installed in their new factory at Twelfth and Cranbury streets. The building is a fine two-story structure, 50 by 100.

The General Incandescent Arc Light Company have issued Circular No. 5, setting forth the advantages of their many styles both of direct and alternating current lamps. Prices and full information as to sending orders are given.

The Columbia Lamp Company of St. Louis report increasing sales and the most prosperous of all business in the history of the company.

Queen & Company, Incorporated, Philadelphia, have a new projection lantern, called the "Paragon," with which they claim to produce a perfectly steady white light, far superior to the oxy-hydrogen jet, and at the same time very much more convenient to operate. Already a number have been supplied to prominent schools where such apparatus is absolutely essential in the proper illustration of scientific lectures. The lamp is adapted for direct or alternating currents as desired.

Over 2,000,000 feet of tubing for inside wires of the well known and popular type made by the Interior Conduit and Insulation Company have been sold since January 1 of the present year by the Eastern Agents, the Pettingell-Andrews Company of Boston. Such a sale by one firm alone in the time above stated is evidence enough of the value of this conduit, which is in use everywhere, and still sells as actively as ever.

The Pettingell-Andrews Company of Boston, the largest electrical supply house in New England, report splendid results from a unique method of bringing special lines before the fraternity. Every month they mail a postal card addressed to each of their customers and the trade generally. On the obverse side their attention is called to some specialty in very few words. A fresh specialty is thus announced every month. These postals bring back quite a steady flow of good orders, for users are reminded of their needs by the announcement on the postal.

Hutchins, Longford & Hutchins, is the full title of a firm established recently in Providence, R. I., for the sale of every kind of gas and electric fixtures and for the execution of electrical contracts. The partners in this firm are all young, enterprising and competent men, who have had a varied experience in the business, and are in a position to undertake any and all kinds of electrical construction work. They carry a full line of supplies, are well known in Providence and surrounding towns and commence business under very encouraging auspices.

Albert and J. M. Anderson, the well-known manufacturers of Ætna Railway Insulators, Anderson Line Material, Ajax Switches and Switchboards, Pivotal Boston Trolleys and other useful electrical devices, have found it necessary to vacate their factory in Hamilton street, Boston, and have leased a much more extensive one, being Nos. 289 to 293 A street, Boston. The business done by this firm has increased so phenomenally, owing to the high grade character of all their goods, that a bigger factory became imperative, and the outlook for a yet still greater growth is most promising.

Riehle Bros.' Testing Machine Company, Philadelphia, are pleased to report indications of an improvement in business, and consider permanent prosperity near at hand—as soon as legislation at Washington reaches some definite policy. Among recent orders they report the following: 20,000 lb. Horizontal Testing Machine, 10,000 lb. Vertical Screw Power Testing Machine, Canvas Testing Machine for the U. S. Government, Warehouse and Railroad Trucks for export, 3,000 lb. Transverse Testing Machine, 1,000 lb. Cement Testing Machine with worm gear, "Star" Cement Testing Machine, 40,000 lb. Screw Power Testing Machine, two 1,000 lb. Cement Testing Machines, 100,000 lb. Testing Machine, six 20 ton Riehle-Roble Protected Ball Bearing Screw Jacks.

INCORPORATIONS.

The Progressive Power Company, Jersey City, N. J.—to manufacture engines, boilers, etc., and appliances, chemicals, etc., for the production of light, heat and power. Capital stock, $300,000. Promoters: Julius H. Batt, Montclair, N. J.; W. K. Lothrop, F. G. Wheeler, E. F. Leeds, Jas. P. Lowrey, New York City.

The Aurora Electric Light and Power Company, Aurora, Mo.—to furnish electricity for lighting streets, houses and running all kinds of machinery. Capital stock, $20,000. Promoters: E. L. Foster, Independence, Kan.; M. T. Davis, W. F. Branham, J. J. Rehm, Aurora.

Metropolitan Electric Company, at Chicago. Capital stock, $300,000. Incorporators: Edwards Elliott, John E. Campbell and Henry A. Ritter.

West Chicago Light and Power Company, at Chicago. Capital stock, $60,000. Incorporators: F. T. Barber, Grove E. Walter, Charles J. Bushy.

Chicago Electrorama Company, at Chicago. Capital stock, $25,000. Incorporators: William P. Sibley, Charles H. Hamill and William J. Louderbeck.

The E. Walley Jones & Son Company, Seattle, Wash.—to operate and maintain electric light and power plants, etc. Capital stock, $30,000. Promoters: E. Walley Jones, E. J. McKittrick, C. Winkley and others.

The Domestic Electric Power and Light Company, Baltimore, Md.—to manufacture the Hanson primary battery and carry on a general electric business. Capital stock, $50,000. Incorporators: Samuel Kimberly, of Norfolk, Va; John H. T. Jarome, Allen B. Howard, Jr., John C. Powell, George H. Dobson and Bruno R. Koering.

The Marlborough Electric Light Company, Marlborough Ulster County, N. Y.—to furnish electric light and power Directors: O. B. Whitney, Moses McMullen, E.E. McNamee A. A. Sudderly, E. Dayton, G. A. Bodner and W. A. Paltz.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED SEPTEMBER 12, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

504,734. Trolley-Head. Joshua P. Maddox, Westbrook, Me. Filed Oct. 7, 1892.

504,847. Conduit Electric Railway. Henry D. Oler, Paterson, N. J. Filed Aug. 23, 1892.

504,977. Supply System for Electric Railways. George F. Green, Kalamazoo, Mich., assignor of one-half to Oliver S. Kelly, Springfield, Ohio; Martha L. Green executrix of said George F. Green, deceased. Filed Feb. 13, 1892.

505,081. Conduit Electric Railway. Charles O. Ehlert, New York, N. Y. Filed Aug. 23, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

504,743. Socket for Incandescent Electric Lamps. Charles G. Perkins, Hartford, Conn. Filed July 10, 1891.

504,751. Electrical Testing Apparatus. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Jan. 14, 1888.

504,753. Electrical Testing Apparatus. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Feb. 8, 1889.

504,760. Electric-Arc Lamp. Charles F. Snedekor, Worcester, Mass., assignor to the Washburn & Moen Manufacturing Company, same place. Filed March 20, 1893.

504,815. Carbon for Electric Arc Lamps. Robert McManus, Brooklyn, N. Y. Filed Oct. 27, 1892.

504,845. Carbon for Electric-Arc Lamps. Robert McManus, New York, assignor to William A. Powell, Brooklyn, N. Y. Filed July 8, 1892.

504,866. Electric-Light Fixture. Frank W. Davenport, Providence, R. I. Filed July 22, 1893.

505,051. Electric-Arc Lamp. William B. Luce, Brookline, Mass., assignor of one-third to Edward S. Ritchie & Sons, same place. Filed Dec. 5, 1892.

505,060. Portable Electric-Lamp Support. Norman T. Mills, Boston, Mass. Filed Oct. 15, 1892.

DYNAMOS, MOTORS, ETC.

504,740. Portable Static Electric Machine. Theodorus H. Patee, Chicago, Ill. Filed Dec. 9, 1892.

504,904. Multiphase Motor. Louis Bell, Boston, Mass., assignor to the General Electric Company of New York. Filed Nov. 4, 1892.

504,914. Dynamo-Electric Machine. Rolfe Eldridge, New York, N. Y. Filed May 13, 1891. Renewed June 3, 1892. Again renewed June 1, 1893.

505,063. Switch for Governing Electric Motors. Edgar F. Ramlen, Milwaukee, Wis., assignor, by direct and mesne assignments, to Horace Hobbs, Augustus W. Friese, and Henry W. Ramlen, same place. Filed April 8, 1893.

505,064. Switch for Controlling Electric Motors. Harry Sawyer, Muskegon, Mich., assignor to the Shaw Electric Crane Company, same place. Filed Feb. 20, 1893.

BATTERIES.

504,746. Galvanic Dry Battery. John von der Poppenburg, Charlottenburg, assignor to Carl Christian Lesenberg, Rostock, Germany. Filed Oct. 11, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

504,732. Printing-Telegraph. Samuel R. Linville, Philadelphia, Pa., and Louis F. Hettmansperger, Camden, N. J., assignors to the United States Printing Telegraph Company, Philadelphia, Pa. Filed Dec. 16, 1892.

504,797. Restoring System for Annunciators. Louis A. Berthon, Paris, France, assignor to the Societe-Generale des Telephones [Reseaux Telephoniques et Constructions Electriques]. Filed May 17, 1893.

504,801. Telephone-Transmitter. James A. Brown, Moline, Ill. Filed April 25, 1893.

505,070. Telephone-Switch. Josef Steiner, Brooklyn, N.Y., assignor to the Western Electric Company, Chicago, Ill. Filed Oct. 19, 1891.

SIGNALS AND SIGNALING APPARATUS.

504,745. Electric Signal Device. Charles R. Figgins, Racine, Wis. Filed April 4, 1893.

504,752. Electric Signal Device. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Dec. 10, 1888.

MISCELLANEOUS.

504,703. Electrolytic Diaphragm. August Breuer, Iserlohn, Germany. Filed Jan. 4, 1892.

504,738. Electric Switchboard. Frederick W. Mount, St. John, Canada. Filed April 5, 1893.

504,741. Electric Door Register for Watchmen. William R. Patterson, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Jan. 31, 1889.

504,754. Electric Measuring Apparatus. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Oct. 19, 1891.

504,774. Electrolytic Cell. Thomas Craney, Bay City, Mich. Filed Feb. 13, 1893.

504,827. Electro-Mechanical Gong. Franklin M. Dunn, Baltimore, Md. Filed June 23, 1892. Renewed June 9, 1893.

504,901. Commutator Brush Holder. Robert N. Bayles, New York, N. Y. Filed March 30, 1893.

504,938. Electric Cut-Out. Herbert N. Prentice, Stowmarket, England. Filed May 31, 1893.

504,980. Electrical Alarm System. Charles K. Hall and William B. Lillard, New Orleans, La. Filed Nov. 2, 1892.

505,025. Magnetic Clutch or Coupling. George A. Brown, Muskegon, Mich. Filed Feb. 11, 1893.

505,032. Automatic Safety Joint for Electric Conductors. James H. Curry, Wilkinsburg, Pa., assignor of eighty-three-one-hundred-and-twenty-eighths to Frank B. Tomb, same place, and Samuel J. Graham, A. H. Childs and Robert A. Gillespie, Pittsburg, Pa. Filed Nov. 18, 1892.

505,062. Electric Time Recorder. Charles E. Ongley, New York, N. Y., assignor, by direct and mesne assignments, to the Ongley Electric Company, same place. Filed Jan. 24, 1891. Renewed Nov. 16, 1892.

505,065. Hoisting Machinery. Alton J. Shaw, Muskegon, Mich., assignor to the Shaw Electric Crane Company, same place. Filed Nov. 15, 1892.

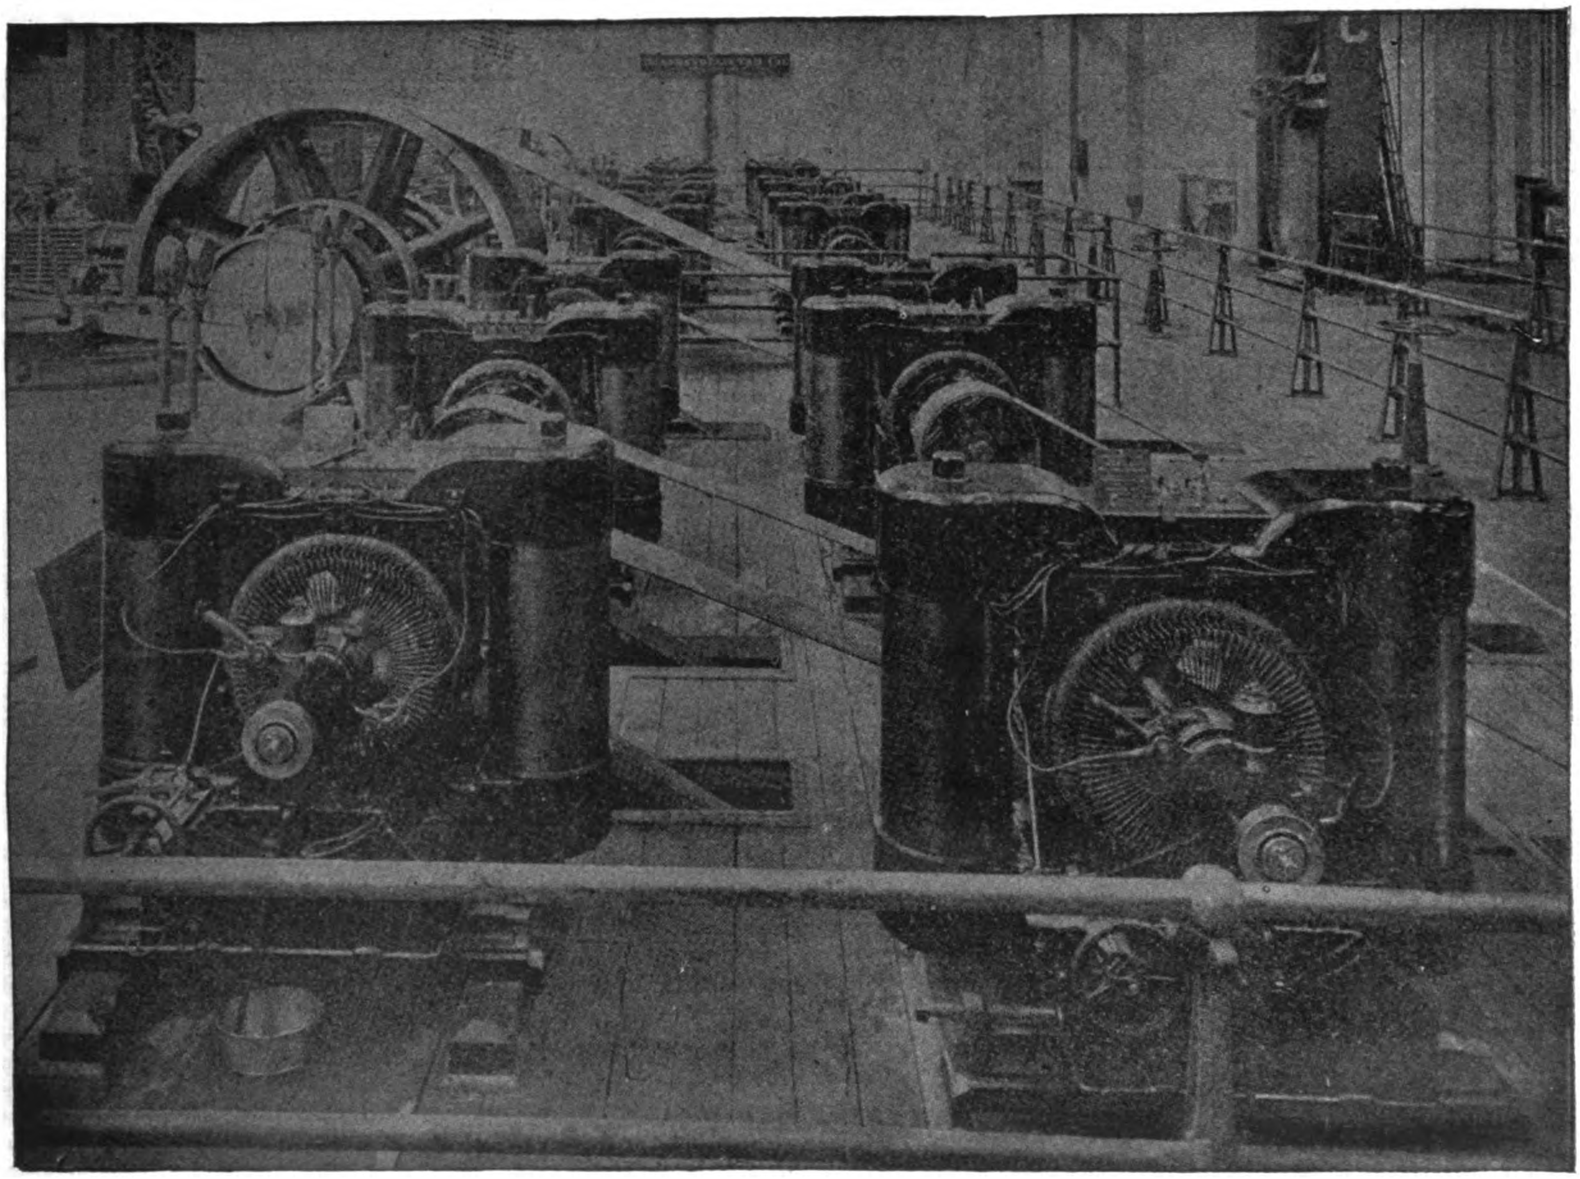
505,066. Hoisting Machinery. Alton J. Shaw, Muskegon, Mich., assignor to the Shaw Electric Crane Company, same place. Filed Feb. 11, 1893.

505,067. Hoisting Machinery. Alton J. Shaw, Muskegon, Mich., assignor to the Shaw Electric Crane Company, same place. Filed Feb. 17, 1893.

505,068. Hoisting Machinery. Alton J. Shaw, Muskegon, Mich., assignor to the Shaw Electric Crane Company, same place. Filed March 6, 1893.

ELECTRICITY.

VOL. V. NEW YORK. OCTOBER 11, 1893. CHICAGO. No. 13



STANDARD ELECTRIC COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 150.)

The Standard Electric Company.

One of the largest arc lighting plants at the World's Fair is that of the Standard Electric Company, which is located in Section S, Machinery Hall. The plant contains 20 dynamos, each having a capacity of fifty 2,000 candle power lamps, besides two other machines, one of 50 and the other of 60 lights capacity in another part of the building. In all, these machines are capable of running over 1,100 arc lamps.

The two rows of dynamos, shown in the Frontispiece, are driven by three engines. The four further ones are directly belted to a 200 H. P. single cylinder Erie City engine. The next four are driven by a 210 H. P. Russel compound engine and the remainder by a double tandem compound Russel engine of 500 H. P. The latter engine runs a line shaft beneath the floor to which the dynamos are belted.

The lights from this plant are distributed through several buildings and about various parts of the Fair grounds. All the lamps run from this plant are of the Standard Company's make.

The dynamos in this plant are divided into blocks and a special switchboard is arranged so that any two circuits can be switched from one block to another in case of accident. These machines are of the Manchester type with cast iron pole pieces and wrought iron spool cores. The bearings are self-oiling and self-adjusting for alignment and their operation has been specially remarked by visitors on account of its smoothness and freedom from sparking.

A feature of the machine which also commends itself is the ease with which repairs may be made. The parts are easily separated and replaced and the bolts, screws, etc., are made of the standard commercial sizes.

Prof. von Helmholtz at Columbia College.

Prof. von Helmholtz Thursday afternoon delivered an address to the students of Columbia College in the lecture-room of the Law School building.

In addition to the students there were present Prof. Bell, Dr. Knapp, President Low, Profs. Van Amrinde, Rood, Ware, Butler, Rees, Keener and Jackson. President Low introduced Prof. von Helmholtz, who said that as his audience was composed of students from all the schools of the university he would deal with an abstract subject, "The Nature of Science and the Part that it Plays in Human Affairs." He said that the recognized method of scientific work now was collection of knowledge, retention of that knowledge and its communication to mankind. There has been more accomplished by science during the last two centuries than during 2,000 years previously.

Careful observation makes the artist and makes the brilliant scientist; trace the connection between events and the laws that govern that connection until doing so becomes intuitional. Train the mind so that the strongest impressions will be made by the most important events until this also becomes intuitional. Follow the advice of scientists of the last two centuries and go on by careful, accurate, complete observations to great discoveries and great successes.

Mr. Hurluf Petersen, of Milwaukee, has just patented a kind of electric railway which will do away with the overhead wires in the running of electric railway cars and make use of underground conductors by means of an opening between the rails similar to a cable line. Mr. Petersen is sanguine of the success of the invention. He says it is automatically and scientifically as nearly perfect as it can be made, and that it only needs a trial to prove its utility.

Direct Currents by Mathematical Methods.

BY LIEUT. F. JARVIS PATTEN.

The sometimes jocular vein of the editorial columns of the London *Electrician* threaten to make the inside pages of that sheet as bright as their lurid vermilion cover. Here is the latest, from the issue of September 1, which I reproduce for the benefit of this nation of inventors:

> Now and again we hear of the efforts of some inventor to produce a continuous current, such as may be used for charging storage cell from a simple periodic current. Various rectifying commutators have been tried, but these can only produce a humpy sort of current, the sole merit of which is that it is always in one direction; a current which must be clipped up into useful and useless portions before storage cells can be charged by it. Fourier's theorem, the refuge and strong tower of alternate current mathematicians, tells us, of course, that a certain combination of simple periodic currents *will* give an absolutely steady current; but, theoretically, at any rate, the desired result can be obtained in a much simpler manner. All that is necessary is to be able to produce a current which shall vary as the *square* of the sine of the time, instead of, as now, as the first power. Two such currents having equal periods, but superposed in quadrature, would give a perfectly steady current such as would make a battery man's mouth water. When we were at school we were taught that the sum of the squares of the sine and cosine of an angle was constant and equal to unity. Is there no one who can invent a transformer which will utilize this simple trigonometrical fact?

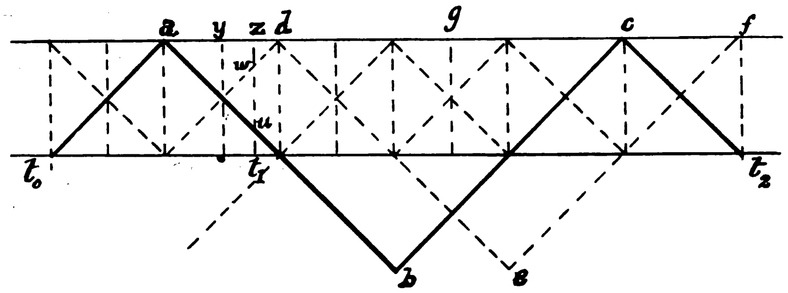


FIG. 1.

I am ever on the lookout for such great opportunities, for I have been trying for years to make steady currents out of unsteady currents but could not. Now, thanks to this kind hint thrown broadcast to the world, I think I can, but not on the plan suggested, for I was never aware that time, pure, simple, easy going time, had a sine much less a squared sine.

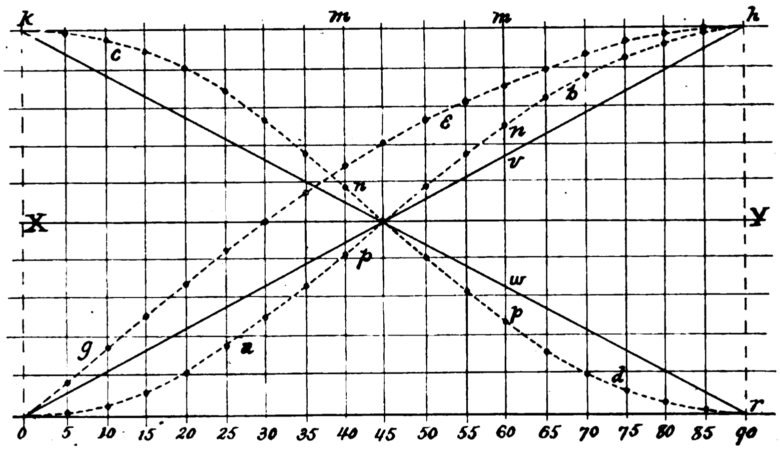

FIG. 2.

Passing this by, however, as a mere slip of the quill, devoid of any intent to mislead, let me get at that steady current that has no hummocky humps, and if I don't find something that varies as the square of the sine of the time I'll get something at any rate that "beats that twice over," and without using Fourier's theorem or the towering mathematics of the coexistence and superposition of greater and lesser harmonics, for I like a "bee line" even if it does wobble round like a Virginia rail fence, with only its corner points planted in the mud. Besides, the square of the sine method is elusive and unsatisfactory; all the negative sines come out with positive squares, and so do the plus sines also, making a one sided old-fashioned direct current that is now altogether out of date.

I am weary of those everlasting sines and cosines, and for a change let's go off on a tangent. A tangent has the faculty of being straight, and we may be able to do something with it; and I find the equation of a straight line in space when referred to a system of rectangular co-ordinates is

$$y = m \tan. x$$

and for another line $y_1 = - m \tan. x + a$

whence we have $y + y_1 = a = $ a constant,

which leaves us to infer that if varying currents expressed by ordinates that vary directly as the time, and not as the sine, of a variable function (the angle of rotation) itself varies directly as the time, then two such currents may be so superposed that the sum of their values (the ordinates) at all times will be a constant.

The condition is that these currents must vary directly as the time between the same positive and negative limiting values, and that the time of maximum value of one current, positive or negative, must correspond to the zero value of the other. The geometrical construction of this great truth seems too self-evident to have escaped the notice of all the searchers for smooth, uniform, direct currents without any "bumps." All that is required are two equal and similarly varying currents, a b c and d e f, Fig. 1. Such currents vary directly as the time, and not as the sine of the angle regarded as a function of the time, as we have been accustomed to make them, or heretofore regarded them as being made—quite a fallacy on the whole, for many alternators come nearer to making the zigzag rail fence curve bounded by two straight lines than the sine curve so much figured on. The assumption of this zigzag rail fence curve as a true expression of the varying current values from instant to instant will do away with much of the complexity incident to the analysis of sine functions. As, for instance, two such currents superposed in quadrature, i. e., maximum of one corresponding in time to the zero value of the other, give as a result an absolutely uniform direct current, a y d g c f, because at any instant as t_1 the small part t_1 u is equal to w z for any and all positions of the ordinate y.

This shows that if you can make an alternating current that will vary directly as the time between equal, positive and negative maxima, then two such currents superposed in quadrature and rectified, i. e., all negative impulses reversed, will give a uniform direct current that will be free from fluctuations, and such a current does not require, as generally supposed, the superposition of many currents of different phase, which in turn are rectified; but any two currents will answer the sum of whose ordinates remain constant.

This we see is a more general law, and if we construct a curve that varies as the square of the sine, as suggested by our English friend, it will fulfil the condition required as well. Thus in Fig. 2 the diagonals g h and k r represent quarter periods of such straight line currents—where o w is always equal to v m; and the sum of the ordinates is always a constant.

Now, g e h is a quarter period of a sine curve, the ordinates being sine values of angles from 0° to 90° and the curve a, p, u, b is one the ordinates of which are proportional to the square of the ordinates of the sine curve. In other words, the two curves, x, c, w, r and a, b, h, are quarter periods of curves that vary as the square of the sine, and being in quadrature with each other, they are also symmetrical with respect to x, y, which is the condition which must be met in order that the sum of the ordinates shall be a constant as required. Any two curves or lines that are symmetrically disposed about the line x y will then fill the required condition.

Evidently any of these curves are easily obtained. Kapp, in his recent little work on alternating currents, pages 65 to 69, shows how the zigzag current is produced by well-known forms of alternators, and the sine square curve, which it is seen differs but little from the sine curve itself, can be easily obtained were it desirable to do so, by slightly modifying the shape of the pole pieces, and properly spacing them.

From all this we may infer that two windings on an ordinary alternator so arranged as to give currents in quadrature, and following any curves or lines that are symmetrical with the line x, y, will, if rectified by separate commutating devices and superposed after rectification, give a uniform direct current without the objectionable "humps."

Unfortunately, we have to rectify, for the dynamo hasn't yet been taught algebra, and don't seem to know how to get a plus or positive quantity by multiplying together two negative ones, which it ought to be taught to do at an early day, and that is what our English friend in fact suggests.

The following experiment for making visible lines of electric force is described by Herr Bruno Kolbe: Into a flat cylindrical vessel pour purified anhydrous oil of turpentine to a depth of about two centimeters, and some sulphate of quinine. To the rim of the vessel attach two wire springs, adjusted so that the two small metallic balls at their ends dip into the turpentine. Stir the quinine with a glass rod so as to distribute it evenly, and place the vessel on a black cardboard. Join the two wires to the terminals of an influence machine, and turn very slowly. At once the white crystals group themselves so as to form beautiful curves, representing the "lines of electric force." The form of these curves recalls that of the brush discharge of the influence machine. Prof. Weiler, of Esslingen, gives the following experiment: Prepare a milky mixture, stirring up finely divided quinine in oil of turpentine. On sending a series of discharges through it, a clearance is produced at the positive pole, and the particles cluster round the negative pole, arranging themselves in streamers directed along the lines of force.

On an Improved Form of Instrument for the Measurement of Magnetic Reluctance.

BY A. E. KENNELLY.[*]

Of the methods that have been adopted for the measurement of magnetic permeance or reluctance of iron, the Faraday ring test with ballistic galvanometer is generally admitted to be the most accurate and reliable. It is, however, essentially a laboratory measurement, requiring considerable time in preparation, execution and computation. For workshop measurements and comparisons, tractive and magnetometric methods have been employed with a convenience and facility usually obtained at some sacrifice in accuracy. Recently, instruments have been used with success in which the reluctance of a sample bar of iron is compared with that of standard bars of soft Norway iron, notably the magnetic bridge of Mr. Thomas A. Edison exhibited at the Paris Exhibition of 1889, and the differential magnetometer of Mr. R. Eickemeyer.[†] It is proposed to here describe a new instrument of this class, for which certain advantages may perhaps be claimed.

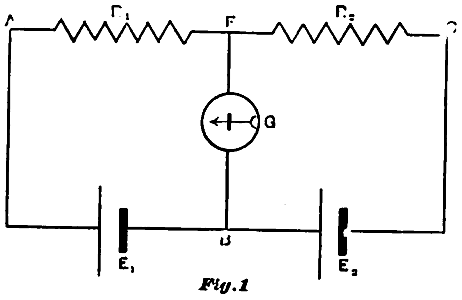

Fig. 1

Fig. 1 represents the well-known galvanic arrangement of circuits in which two resistances R_1 R_2 can be compared by a null method. E_1 and E_2 are two equal and constant E. E. forces, inserted in the conducting paths A B and B C of equal resistance. The galvanometer G connecting the junction F of resistances with the junction B of electromotive forces will indicate no current when R_1 and R_2 are equal. The conductor F B corresponds to the neutral wire of a three wire system of electrical distribution.

Fig. 2 represents the corresponding condition of magnetic circuits. A B C is a stout vertical frame of annealed Norway iron with two coils M_1 M_2 wound with the same number of turns of wire, connected in series so as to develop, with regulated constant current strengths, equal definite M. M. forces. The upright G corresponds to the galvanometer arm in Fig. 1, while the bars A F and F C are test pieces of iron having a cross-section considerably smaller than that in the remainder of the circuit. One, A F suppose, is a standard section made up of one or more bars of soft iron whose quality is known, while the other, F C, is the bar whose reluctance is required.

If the two reluctances R_1 R_2 are equal, the magnetic potentials at F and B will be equal, and the bar G will remain unmagnetized when the coils M_1 M_2 are excited. On the other hand, if R_1 and R_2 slightly differ, the potentials at F and B will not coincide, and magnetic flux will traverse the bar G. Since the magnetic circuits are all closed, the leakage through the surrounding air will be symmetrical and usually negligible, so that calling Φ the flux through the main circuit, and that through G, φ

$$\varphi = \Phi \frac{R_1 - R_2}{R_1 + 2\,G}.$$

In order to ascertain whether flux did traverse the bar G, we might, according to established principles,[‡] cut in imagination an indefinitely narrow gap or crevice through G in a horizontal plane, and insert therein a magnet pole with apparatus to measure the tractive force to which it would be subjected. As the nearest practical approach to this plan, we can cut a gap across G $\frac{1}{16}''$ (0.16 cm.) wide, and swing in the crevice a flat disk armature, carrying a steady feeble current, and with an attached pointer or index close to a fixed scale. We then obtain in all essential features the instrument here to be described.

Fig. 3 represents to scale in front and side elevation the actual instrument. D is the disk armature wound with 100 radial wires from center to circumference. Half of this disk is always covered by the pole pieces above and below it. The unifilar suspension attached to the points P and Q supply a current of about ten milliamperes to this disk. A sensibly constant tension upon the suspension is obtained by means of a spiral spring within the lower slide tube, and it can be readily shown by experiment or computation that small variations in the tension of such suspensions have a very small influence upon the torsional moment.

The modus operandi is as follows:

A sample strip or flat bar of the iron to be tested is laid across the gap F, C, the breadth of the bar being conveniently one inch (2.54 cms) and the height $\frac{1}{2}''$ (1.27 cms.) Strips of soft iron to match this are laid across the gap A F in parallel, each being say $1'' \times \frac{1}{8}''$ (2.54 × 0.318 cms.) If the disk circuit is then closed, and if there is no appreciable residual magnetism in the apparatus, the disk will remain uninfluenced and its index at zero. The field magnets are now excited in series with a suitable and measured current. The disk and pointer will now move to one side or the other about the axis of suspension according to the preponderance of reluctance between the two sides, and soft iron strips have to be added or removed across A F until balance is restored. Generally balance will be found between two adjustments of cross section at A F, and the proper amount can then be computed by proportional parts.

Steinmetz has shown[*] that from a series of such adjustments to equalize between standard and sample bars at various excitations, the complete hysteresis curve of the sample can be deduced through the known valuations of the standard, but since a linear relation is found to exist between the reluctivity and magnetizing force in iron above the critical intensity, two such observations are theoretically sufficient to determine the reluctivity of the sample for supracritical magnetizing forces.

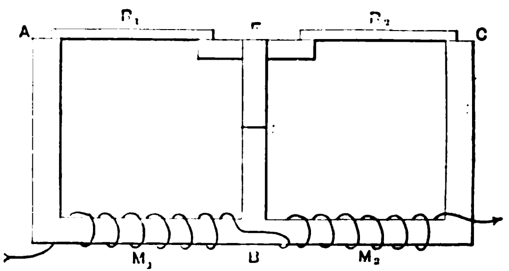

Fig. 2

The instrument can also be employed to readily indicate the retentiveness of sample bars of hard iron or steel. If after a balance has been obtained at a noted excitation the excitation be withdrawn by interrupting the circuit of the coils M M, and the standard bar is removed, the residual flux from the rest piece will, disregarding some slight loss by leakage, pass entirely through the air gap and disk at D. If the constant of the disk has been determined independently, the deflection of the pointer for the observed current through the disk will supply the amount of this flux.

---

[*] Read before the International Electrical Congress, Chicago.

[†] The *Electrical Engineer*, March 25, 1891.

[‡] Clerk-Maxwell. "Electricity and Magnetism," Vol. II, par. 396.

[*] Transactions of the American Institute of Electrical Engineers, Vol. IX, p. 33. Jan., 1892.

If N denotes the number of turns in each spool,

I the current strength exciting the spools (amperes),

l the length of the test bar (cms.),

g the reluctance of the air gap at the disk (C. G. S. U.),

H_1 the magnetizing force in the bar during excitation,

H_2 the magnetizing force in the bar with excitation,

Then the M. M. F. of excitation is $\frac{4\pi}{10}$ NI in each coil; and since the intensity in the test bar is considerably greater than in the field frame, the magnetizing force brought to bear upon the test bar is nearly $\frac{4\pi}{10} \frac{NI}{l}$.

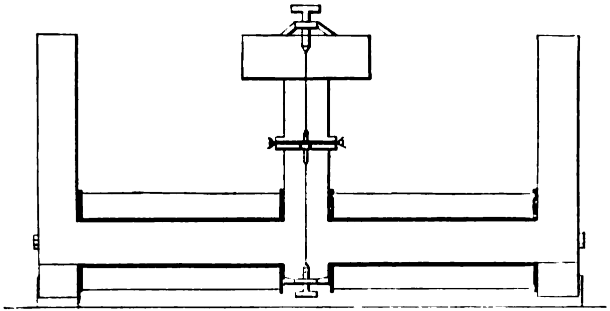

Fig.3. Sectional Elevation.

After removing the excitation and standard bar, the observed residual flux encounters at the air gap a reluctance g, so that neglecting the comparatively small hysteresis of the soft iron field frame, the counter M. M. F. at the gap is $-\Phi g$, representing an average demagnetizing force in the bar of $-H_2 = \Phi g / l$, so that the relative values of residual flux density are readily found with different sample bars for any selected value of H, or more closely, for any consequent ranges of $H_1 - H_2$.

By mounting two opposed parallel plane iron plates between the uprights A and F, in such a manner that the length of air gap between them can be adjusted by a screw, it becomes possible to measure the reluctance of a bar placed between F and C by direct comparison with the reluctance of air. Trial has shown, however, that the additional contact surfaces involved, the dissymmetry introduced into the two sides of the circuit, and the uncertain leakage error with large air gaps, probably more than offset the advantage to be derived.

The errors attending the use of the instrument are:

1. The variability of reluctance in the field frame.

2. Errors in estimating the reluctance of the contact surfaces, and the effective length of the test bar.

The first source of error depends upon the hysteresis in the iron of the field frame. It can be reduced to small limits by keeping the cross section of the test bar a sufficiently small fraction of the cross section in the frame, thus bringing nearly all the reluctance of the circuit into the test bar. A correction can also be made for the outstanding frame reluctance.

The second source of error is common to all forms of permeameters in which straight test bars are employed in closed magnetic circuits. There will be a certain range of reluctance in the contact surfaces that can be kept in subjection by giving to those surfaces adequate area. There is also the more complex error due to misestimation of the effective bar length, for the reluctance of the bar will not only be encountered in the distance between the supports F and C, but also by some portion of the length resting on the supports. The virtual length of bar included in the circuit will thus be a function of the intensity within it and will not generally be the same for the test and standard bars.

The advantages of the instrument are:

1. Absence of hysteresis in the moving and indicating parts which contain no iron.

2. Great sensitiveness and control.

3. Small reluctance in the narrow air gap or path of differential magnetization.

4. Convenience in comparing retentive powers in steel.

The writer desires to acknowledge his indebtedness to Mr. Thomas A. Edison, in whose laboratory this instrument was constructed.

A New Method for the Control of Electric Energy.

BY D. MCFARLAN MOORE.[*]

The rapid growth of electrical science, and the almost daily unprecedented addition to it of new inventions, have caused those well versed in the present state of the art to greet new theories with a certain amount of doubt, owing to the large number of false alarms that have been sounded to tell the world that all present theories and methods will, in the future, be history; and that a new and revolutionizing principle has been discovered.

Be that as it may, there is reason to believe that this paper treats largely of a heretofore uninvestigated branch of electrical science and phenomena which may be of great value to the commercial world, and of even greater interest to the scientific world.

The key to this branch of science may be expressed in a few words, viz.:—a varying-in-pressure contact in a vacuum, produced by a variable magnetic field.

The present means for the control of electric currents—ohmic resistance—is crude at its best, as in any form it is an uneconomical device. All existing forms of rheostats, regulators, resistance boxes, controllers, etc., are bulky, clumsy means for accomplishing a desired object. This is conspicuously illustrated in the case of stage regulators, which often occupy valuable floor space and consist of a tremendous weight and length of wire. That the design of apparatus for controlling current is a matter of great importance and is essential to all electrical installations, is exhibited in the fact that over half of the catalogues issued by electric manufacturing companies are given up to this class of electrical goods. Many problems in electrical engineering are considered impracticable, simply because of the weight and space required for resistance to enable the control of the current as desired.

When one takes into consideration the multitude of switches of every conceivable shape, construction and design, but all having one aim in view—which none perfectly accomplish—viz., to break a current without deleterious sparking, it seems that, as all are designed on the same principle, a new principle should be employed which would perfectly accomplish the object desired; that is, break the current with practically no sparking. It would also be a very convenient feature if each switch would control the brilliancy of all lights on the circuit which it controls.

The regulation of intensity of the incandescence of an electric filament has been a problem, the solution of which has been sought after by electricians in general the world over, and partial success has been attained by the use of the only known means, "dead resistance"; but this method can never be commercially successful, on account of very objectionable bulk, weight and heating of the resistance.

The public in general demands the control of electric lamps and the great convenience gained thereby.

The massive regulators of dynamos and starting boxes of motors should be supplanted by devices occupying but a few cubic inches of space. This is especially the case where the motor is not stationary, as in electric railway work.

There is room for a cheap ampere meter, and still more room for a cheap mechanism to be used as an electric gauge; that is, an instrument which can be adjusted or set so that a current that has passed through it will have any desired quantity or quality. This device could be substituted in place of fusible cutouts and the multitude of appliances of a similar nature. It would be of great value in telegraphy. The application of electricity in medicine should also be improved. Lastly, the reducing of phosphorescent lighting to a commercial basis is desirable.

It is hoped that a solution of these and many other problems lies in the principle stated at the beginning of this paper, i. e., a varying-in-pressure contact in a vacuum produced by a variable magnetic field; and it is doubly valuable in that it can be applied both to the alternating and the direct current. One of the simplest forms of apparatus designed for meeting these conditions is shown in Fig. 1. The varying-in-pressure contact is shown at A, caused by the variable magnetic field due to the movement of the magnet B by thumbscrew C. The evacuated bulb F contains the armature E, supported by spring E, permitting it to vibrate rapidly, producing pulsations or interruptions of the current. The rate or degree of these interruptions depends on the strength of the magnetic field surrounding the armature (in this case acting through the glass), which in turn depends on the distance of the magnet from it, varying inversely as the square of the distance. Varying the magnetic field, and therefore the pressure on the contacts, changes the amperes and volts of the current passing through the device. With properly designed apparatus the movement of the armature is so slight that to all appearances one would think it at rest. In the discussion of this method of current control, let us select that form of translating device known as the incandescent electric lamp. Fig. 2 is a diagram showing the action of a vibrator in series with a lamp without the contacts in a vacuum.

Its action is as follows:—Contact made at A; current flows through magnet and armature is attracted, breaking the circuit; magnet loses its power and spring S again closes the circuit.

Fig. 3 shows the device as applied to each individual lamp, and it will be noted that in this case the vacuum of the lamp is utilized for the vacuum of the contacts as well. The size of the armature is made as light and small as possible not only on account of the general law of all mechanical construction, viz., make moving parts as light as compatible with strength so that the position of the lamp will have no effect on the incandescence of the filament, but to minimize the amount of residual gas in the metal composing the armature, as any foreign gas will be detrimental to the filament.

---

[*] Read at the seventy-ninth meeting of the American Institute of Electrical Engineers, New York, September 20, 1893.

In Fig. 4 a socket of ordinary dimensions is shown constructed on the same principle. A socket of this kind can be adjusted to regulate a lamp of almost any C. P. within limits.

In both of these instances the movement of the magnet produces the regulation, but it is evident that results would be the same by either the movement of the vacuum or the core of the magnet. The filament emits continuous light with an illuminating power corresponding to the rate of vibration of the armature. When the armature is not within the inductive distances of the magnet it is at rest, and the filament being in circuit the light is at its maximum. An attachment to the means for adjusting the magnet is used to break the circuit when it is desired to extinguish the light. Tests show that the volts and amperes vary directly with the light. This is apparent from the following table, a 16 C. P. lamp being used :

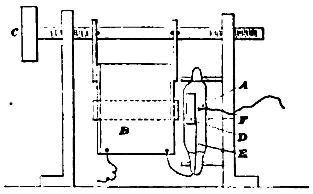

FIG. 1.

Amperes.	Voltmeter No. 2. (See Fig. 2).	Voltmeter No. 1.
.42 full C. P.	115	0
.30	84	31
.17	52	63
.11	35	80
.07	20	95
.04	15	100
.03	10	105
.02 just visible.	5	110

Still lower readings were taken, but below .02 ampere the heating of the filament was not discernible by the eye.

As shown by the readings of voltmeter No. 1, the more rapid the vibrations, the more E. M. F. is required by the contact breaker. Inasmuch as the contacts are in a high vacuum they will remain bright and effective, and the light is regulated without the use of bulk resistance. Again, with this arrangement the current is not thrown on or off the filament suddenly, thus increasing its longevity owing to more gentle treatment. The slight sparking in lamps individually regulated will use up the residual oxygen in the evacuated bulb of the lamp, thus making it more perfect and lengthening the life of the lamp.

It was curious to note that practically as well as theoretically an armature suspended, as shown in Fig. 2, is never perfectly at rest. When a photometrical test would probably decide that the lamp was burning at full C. P., and the screw A pressing the armature B as tightly as the construction of the apparatus would allow against the core of the magnet, if a sounding board is brought into requisition the vibrations of the armature are plainly discernible.

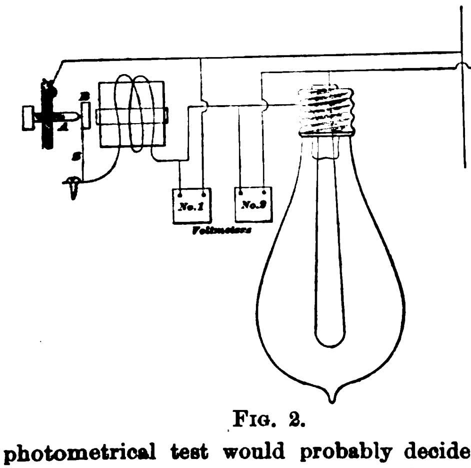

FIG. 2.

An automatic make-and-break, or varying-in-pressure contact, or what has commonly been called, and what has long been sought after, a scientifically formed "poor or imperfect contact," can be used in one sense as a transformer. It will be interesting to note the effect of a large number of lamps of this description working at one time from one dynamo, because if they should accidentally become synchronous the load on the dynamo would be very varying. But such a result is probably impracticable if not impossible.

Now let us again refer to Fig. 2 and note the changes as the lines of force acting at the armature vary.

The vibrator is in series with the lamp, because if in shunt the action is reversed and the liability to short-circuit makes it impracticable.

(1). A and B separated, lamp out.

(2). A and B in contact, lamp full, because B is not in magnetic field of magnet.

(3). Continue to advance A, B enters field, rapid vibrations commence and lamp suddenly becomes dim.

(4). Continue to advance A, lamp gradually brightens until full C. P. is reached.

Fig. 5 shows these periods reproduced diametrically. It will be noted that there are two periods where the lamp can be regulated. Period 2—3 is of too short duration for practical application, however, and by the proper adjustment of the spring can be done away with entirely. Period 3-4 covers the greatest range in C. P. and should be used. The delicacy of the spring supporting the armature determines somewhat the position of point 3; that is, the minimum in C. P. of the filament.

The voltaic arc appears between the terminals of a source of electricity. In the case of the arc lamp, it consists mainly of volatilized carbon. The electrodes are therefore consumed, first by actual combination with the oxygen of the air, second by volatilization. The ohmic resistance of the arc increases with its length and decreases with its area of cross-section. Polarization sets up C. E. M. F., and the extra current produced by self-induction retards magnetic action and causes more sparking. With metallic electrodes the color of the arc is characteristic of the metal, and is of greater length for the same current than that formed between carbon electrodes. To cause electrical vibratory motion, the current must either be greatly weakened or broken. This will cause sparking, which when the life of the contacts is taken into consideration (even though they be in vacuo) should be reduced as much as possible. However, further experimenting may prove the possibility of current regulation by varying the length of the arc in vacuo by means of an exterior magnetic field. Also the construction of a truly incandescent arc lamp on this principle.

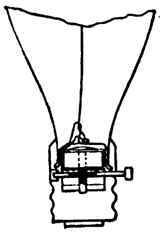

FIG. 3.

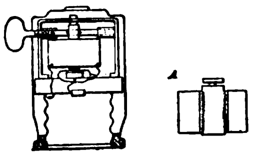

FIG. 4.

Sparking can be relieved in many ways :

(1) Sub-divide the current as much as practicable.

(2) The more rapid the vibrations the more rapid the make-and-break, and consequently the less the spark. To cause rapid vibrations, the point of application of power should be as close to the point of oscillation as possible, or the point of contact should be as far from the point of oscillation as possible.

Magnetic blast, condensers, non-sparking metals, unlike electrodes, high resistance, sheath of copper around bobbin of magnet, metal foil between layers of magnet, separate coils, etc., are all familiar methods.

It is the C. E. M. F., or automatic "choking effect," of the alternating current that permits of its beautiful control without loss, such as is sustained by controlling the direct current entirely with ohmic resistance.

With the method under consideration, the C. E. M. F.'s of the pulsating or intermittent direct current are taken advantage of. That is, both those in the arc and in the magnet.

Besides, when controlling current entirely with ohmic resistances (which can never be completely annihilated), it is constantly in circuit, whereas with the method proposed for lamp control, the only ohmic resistance, that of the arc (that of the magnet being insignificant), is in circuit but one-half of a unit of time, and if there be any foundation for the theory of the persistency of the vision of the human eye, then the filament of the lamp is also dissipating heat but one half the time. Some energy, however, is expended in the continual magnetization of the armature; in fact, this is another reason why the glow of the lamp filament is diminished and why there is a C.E.M.F. in the magnet. The greater the magnet capacity, the less the self-induction and impedance.

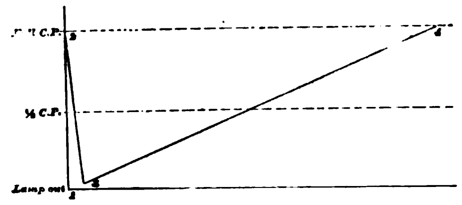

FIG. 5.

(To be continued.)

Mr. McDonald as a Financier.

How the Madison Square Bank was Wrecked.

Talk of the consolidation of the Madison Square Bank (now in the hands of receivers) with the Sherman Bank has brought out the fact that the loans made by the bank to its own officers on insufficient collateral are very large. Mr. Blaut, the president, owes it $80,000, and Mr. R. T. McDonald, one of the directors and largest stockholders, owes the bank about $150,000, directly or contingently as security for the Fort Wayne Electric Company.

What is Necessary.

(From the Commercial Advertiser.)

The duty of stockholders in this concern is perfectly plain. The first thing that they have to demand is an explanation of the methods by which the company has been brought into notoriety. The next thing is to demand an exact statement of the company's financial position at the present moment, especially as regards its notes payable and its contract liabilities, and furthermore, they have to set to work and clear out of the management the parties mainly responsible for the unbusinesslike methods, both commercial and financial, that have brought down the stock from 114 in January of this year to 40. When this is done the General Electric Company will cease to be the scandal and the menace that it has been for the greater part of this year.

The new electric clock of Herr Von Hefner Alteneck may be placed in a circuit like an ordinary incandescent lamp, and is claimed to solve the problem of providing an inexpensive yet effective system of electric control of clocks. The current keeps the clock wound at an annual cost not exceeding that of one 16-candle lamp burning for ten hours—perhaps 8 or 10 cents. Should the circuit be broken, the clock will run without the current about twelve hours. The regulation can be performed by hand from the dynamo room or automatically from an observatory, and consists of a momentary lowering of the circuit potential by 6 to 10 volts at 5 A.M., the effect being to set all the clocks in the circuit at 5. The lamps are not appreciably affected.

ELECTRICITY

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY,
And their Agencies in all Principal Cities.

"Electricity," under its present ownership, has never solicited the advertising patronage of the General Electric Company.

A. I. E. E. Branches. The scheme to establish local branches of the American Institute of Electrical Engineers, which has been proposed for various cities, has been the subject of several editorial criticisms, some of which clearly prove that the proposition has been misunderstood.

The suggestion which is now being considered is simply to have the same papers read at the different local branches of the Institute and discussed by those bodies. These papers under this arrangement would stand upon the same basis as the ones read in former years, and the only practical difference would be the addition of the discussions at the various meetings to the Transactions.

Such a plan seems not only entirely feasible, but it is growing to be an absolute necessity in order to maintain the interest of the distant members of the Institute in its work. The only benefit which such members receive now is the printed Transactions, and something more than this is necessary to extend the influence and add to the membership of the Institute outside the immediate vicinity of New York.

Notwithstanding the plan of establishing local branches grew out of the demands of distant members, a Western contemporary criticises it as follows:

> "It is evident that the committee does not contemplate the organization of a body on an equal footing with the New York association, but merely the establishment of a local branch, a dependency under the control of the Eastern members, taking its orders from the older body, discussing such papers as may be sent out for that purpose; and if perchance an ambitious member of the branch have the temerity to prepare a paper it must be submitted to the parent organization, trimmed and 'edited' to meet the views of the gentlemen who are conferring these privileges upon the Chicago fraternity before it can be read or published in the Transactions."

Whatever the object of such criticism, it is plainly both misleading and unjust, and further, it entirely misrepresents the members of that locality at whose suggestion the present plan was considered. Independent local societies have been tried time and again and proved failures invariably, so that the branches proposed are not likely to interfere with other organizations.

Even our disgruntled contemporary could hardly propose an entirely independent organization parading under the name of the older body, and the talk about "dependencies" at the favor of the New York body is simply a piece of Chicago "bluff," as every branch, including that in New York, would be governed by the officers elected by the whole body of members.

……o……

WE HAVE done the American Institute of Electrical Engineers an injustice by referring to Dr. Adams's paper on the through-by-lightning scheme as having been read before that body in 1892. The paper was read before the Electric Club, which therefore has one more sin to answer for.

……o……

A THOROUGH reorganization of the Sham Electric Trust is demanded.

Central Station Practice. One of the most notable changes in electrical engineering practice from former years is the tendency towards special machinery designed to meet the requirements of special cases, and nowhere is this practice more noticeable than in the equipment of several of our electric lighting stations of recent construction. This fact is true not only in regard to the electrical machinery, but of the steam plants as well, and it is to be noticed further that many of these changes are in line with the practice adopted by European engineers some time before they were attempted in this country.

In the size of units for central station work the change has been most apparent, and we find one machine now replacing five or six of the smaller ones with which stations built a few years ago were invariably equipped. In a number of very large stations the division of the power has been made only sufficient to provide for possible accidents, and in a few others the entire load is ordinarily carried by one machine with a similar one held in reserve for emergencies.

Multipolar fields have also superseded bipolar types for large powers almost completely, and the consequent reduction in speed due to this modification in the design of dynamos has caused a corresponding change in the steam engines used in this class of work. Electric lighting has been credited, and very justly so, with the development of the modern high speed engine, which the demands of central station work have certainly brought to a remarkable state of perfection, but in spite of the nice adjustment and careful balancing of the moving parts, the depreciation of these very high speed machines has been found considerable, and their operation requires the most careful and constant attention.

The avoidance of all countershafting appears to have been the chief motive in the arrangement of a good many plants, and to attain this object a speed of sometimes 275 revolutions per minute and upward was frequently required at the engines so as to belt direct to the generators. The idea of meeting this condition by reducing the dynamo speeds is of very recent date, but the advantages to be gained by this are so obvious that the high speed engine is already disappearing.

The competition in the lighting business has called for the closest economy in the operation of this class of machinery, and the slightest gain in efficiency at any point is not to be neglected. This has been so carefully studied in some of the newest stations that they fairly represent the most advanced ideas in the business. In most of these it is found that the units are as large as possible consistent with the character of the load line, and slow speed multipolar machines are almost the rule. Direct connected dynamos and engines have been found of great advantage for large powers.

Where the size of the station warrants it, the use of automatic appliances to replace attendants as far as possible has proved an economy, not only in the difference in the cost of labor, but in the regularity with which such operations are carried on.

While stations built on these lines mean a large expense for equipment, all of them so far have shown a saving in operating expenses which will eventually prove their economy.

……o……

A Diagnosis of the Situation. The interest which attaches to the condition of the General Electric Company and to its probable future movements is different in degree and in kind from that of a year ago. Then anxious curiosity was expressed as to how high the balloon might soar before it fell to earth; now it has fallen flat, and the trade are all passively waiting for an official and trustworthy statement as to the extent of the damages, the creditors want to know what chance there is of getting their money, and the hundreds of discharged employees how long it will be before they will be put to work again.

ELECTRICITY has little sympathy with the stockholders of the company, who ought to have known better, and hence only a passing interest in the finances. Nevertheless, we are here to give the news, and it seems to us that the chances of the stockholders are not improved. Notwithstanding official denials, the syndicate plan has met with many obstacles, and the cash is not forthcoming as rapidly as was hoped. At least three of the company's creditors have threatened attachments recently in order to collect accounts long past due.

The selling machinery of the company is in even worse condition than it was a month ago. The affairs of the district offices at Syracuse, Cincinnati, Washington and Atlanta are being wound up as rapidly as possible, and the offices will be closed. This and many other changes were no doubt necessary, but a serious blunder seems to have been made in not providing at once, in lieu of the old plan, a single executive head, who might pass on the few orders which are being received. As the case now stands, there is no executive head, for be it remembered Mr. Coffin is shorn of all his powers; the only reason for his retaining the title of President appears to be the reluctance of the Board to kick him out, and his own evident determination to draw his salary as long as possible.

Instead of the former plan, there is now an attempt to run the company by committees—goods are bought by committee and sold by committee, and men are fired by committee. As far as the relations of the company with the trade are concerned this is no improvement on the old plan. The Selling Committee meets Tuesdays and Fridays, and Mr. S. D. Greene is one of the shining lights. It has frequently happened that while this committee has been staring at the ceiling and deliberating, the customer has gone elsewhere to make his purchase. This selling committee contains in its make-up no man who has ever sold goods successfully. There is also a Manufacturing Committee, which contains the best talent in the company, conspicuously Messrs. Upton, Kreusi and Rice, and to which there can be but one objection, which, however, is a vital one. The sessions of this committee take these men away from their posts of duty at their respective factories, where their continuous presence is essential.

Drexel, Morgan & Co. are in absolute and unquestioned control of the company, and Messrs. Coster and Twombly are struggling with the problem of its proper management. We are charitable enough to suppose that the present arrangements are only temporary, and that these gentlemen have a well defined and sensible plan which will be carried out in the near future.

The logic of the situation points to Edward H. Johnson as the only man who can bring order out of chaos, harmony out of bitter strife, and a respected and decently managed company out of the wreck which Mr. Coffin leaves behind.

The logic of the situation also points, with both hands, to the squeezing out of all the water which was injected at the time of the consolidation.

……o……

A Swindler's View of Himself. We have during the past few months received several inquiries from brokers and others as to the merits of the various schemes of Mr. G. B. Pennock. These we have answered privately, as we took it for granted the vast majority of our readers needed no instruction on this point. When such inquiries reach us in the future we shall merely enclose to the seeker after knowledge a printed copy of the following, which was recently sent to the *Electrical Engineer* over Pennock's signature:

> BRIDGEPORT, CONN., Sept. 21, 1893.
>
> I have just read the "roast" your "fake" sheet of the 20th gives me.
>
> I wish you would give my compliments to the so-called Electrical Engineer who claims that he had a "long talk" with me and tell him that he is either a dam' liar or a dam' fool. The man who wrote the article for your "rot" is a dam' dirty thief.
>
> Send your "Gang" up and you'll meet a few honest men who will take great pleasure in "knocking out" a few of the damnest rotten thieves—Dynamo Editors and Dynamo Sharps—who ever scuttled ship or cut a woman's throat.
>
> I am Sir, Your Superior,
> GEO. B. PENNOCK,
> Electrical Engineer and Inventor of the Pennock System.

……o……

They Will Bear Watching. The withdrawal of the Fort Wayne Company from the General Electric Company is not believed by well posted men to be all that has been claimed.

Unless we are misinformed, it is the intention to make the Fort Wayne plant the cornerstone for a new combination. Inasmuch as this company already has three millions of water in its capitalization, it will not prove a very solid foundation.

Whether Mr. C. A. Coffin and Mr. R. T. McDonald win in the sly game they are now playing or not remains to be seen.

ELECTRICITY is looking at them.

……o……

THE WONDER of it is, not that the General Electric Company has ceased paying dividends, but that it ever paid any dividends at all. It has never *earned* a dividend, and if we remember correctly, the payment of any dividend which impairs the capital stock of a corporation is a misdemeanor in this State.

The Telephone Patents. We have been in receipt of a number of inquiries as to the date of the expiration of the Bell telephone patents, which seem to show a desire in a good many cases to take advantage of the liberty to manufacture these instruments as soon as free from the patent.

The patent on the Blake transmitter, it is generally known, expired some time ago, and the patent on the Bell receiver expires on January 30, 1894. After that date anyone can make and use telephones covered by these patents, and there is evidence that a good many will do so, as there have already been several companies organized who are preparing to start business in this field.

The Bell Company owns a number of other patents which are very similar in construction to that of the Bell patent. The Berliner patent, for example, was granted quite recently after being kept in dispute in the Patent Office by the Bell Company, who owned it, but who took this method of extending the time of its usefulness. It will be remembered that this Berliner patent is now undergoing suit for annulment, brought by the United States Attorney-General.

Just what ground the Bell Company may take in regard to those other patents no one outside the company itself can say, but the fact that the Bell receiver and the Blake transmitter will be free after January 30, 1894, is sufficient to warrant the undertaking of their manufacture and use by the public. As to the interference with other more recent patents, that is a question that can only be settled by the Supreme Court.

……o……

THE *Electrical World* has sent out a circular recently, claiming to show that it had lost fewer advertisements than any of its contemporaries during the depression. The statement is not an honest one. If our contemporary would leave out of its calculations the dead advertisements, those of firms who never have paid and never can pay for their space, and the bogus advertisements sent in by its Chicago agent, it would make a less favorable surface showing but one more to its credit. It is not fair to those advertisers who are paying good money for their space for any journal to give the same space away to concerns that are only leeches in the trade.

……o……

THE *Brooklyn Eagle*, which has done more to make the World's Fair a success than any other of the great dailies of the East, has added to its achievements in this line by sending two trainloads of Brooklynites to Chicago on a well-planned "*Eagle* Excursion." Brooklyn is justly proud of the *Eagle*. It furnishes about 360 examples yearly of just what the modern newspaper man thinks a newspaper ought to be. It has not yet attained perfection; but perfection has been reached by only a few of us who read it.

……o……

THE NEXT presidency which Mr. Coffin will hold will doubtless be that of the West End Road. We believe the arrangements are practically completed.

Direct Connected Dynamos with Steam Engines.

BY JOHN LANGTON.[*]

Dynamos directly connected to steam engines have been not uncommonly used in Europe from the first introduction of electric lighting; so much so that the custom has been noted as a distinguishing characteristic of European practice compared with the almost exclusive use of belt driven machines in America.

The early direct connected dynamos were, however, generally uneconomical in material and were in fact high speed dynamos run below their most efficient speed, with a corresponding reduction of output in proportion to their cost. The advances made in the design of multipolar dynamos brought the efficient speeds of this type down to the point where the revolutions per minute compared with the speeds that can be efficiently obtained by modern steam engines, and so made direct connection a general commercial question. The credit for this is very largely due to German engineers and builders, who at the time of the Paris Exhibition in 1889 had brought the type to a high degree of perfection, and had built direct connected dynamos as large as 300 K. W. The general introduction of similar machines into the United States dates from the Paris Exhibition, and since then the rapid increase in their use has been a marked feature in the history of electrical progress on this side of the Atlantic. And although the principal use of machines of this class has been in large sized units, suitable only for large power and lighting stations, the practice has been gradually extended to machines of small power. Under these circumstances the subject would seem a fitting one for consideration by the Canadian Electrical Association, and the object of this paper is to bring the matter before the Association by briefly attempting to discuss in what manner the essential peculiarities of direct connection as compared with belt connection affect the main items which go to make up the cost of producing electrical energy.

The high speed automatic steam engines which are now generally used, belted to dynamos without intermediate shafting, are all suited to direct connection. They thus afford means for an immediate comparison between direct and belt connection which will apply to the majority of cases, and which is divested of all considerations of steam economy by the use of identical engines in both cases. Any conclusions drawn from this comparison, to which the present paper is devoted, may then be taken into account in conjunction with the totally distinct question of steam economy with different types of engines. This is so even for the case of slow speed engines, which in general are not suited to direct connection. The cost of production with high speed belt connected engines may be compared on the one hand with high speed direct driving engines, and on the other with slow speed engines belt driven through intermediate shafting. The question of steam economy has been recently exhaustively treated in a most valuable paper on "The Cost of Steam Power Produced with Engines of Different Types," read before the American Institute of Electrical Engineers by no less an authority on steam engineering than Dr. Charles E. Emery, whose paper gives the items of cost analyzed and tabulated so that special corrections for special cases may be readily applied. (Dr. Emery's paper was republished in the *Canadian Electrical News* of May and June, 1893.)

The subject for present consideration is then narrowed down to the general cases of identical or equally good dynamos, in the one case belt connected and in the other direct connected, to identical or equally good steam engines, used in plants which do not present any special conditions of location or operation. The items of cost to be looked at are:

In the first cost of plant—Cost of generating machinery complete ready for operation. Cost of real estate and buildings to contain generating machinery.

In the operating cost of plant—Repairs and small supplies. Attendance. Fuel.

Notwithstanding some saving in labor and material due to the use of a combined bed plate, the saving of two pulleys, of the whole cost of the belts, and (in situations where they would otherwise be used) of dynamo foundations, it does not seem probable that the first cost of direct connected dynamos and engines erected ready for operation will ever be less than or even as low as belt connected combinations. Any saving of material will be fully counterbalanced by the increased cost of testing the combined machines, whether the engine be brought to the electrical works for this purpose or whether the combined test be made where the plant is erected. Boilers, engines, steam piping, pumps, condensers and electrical apparatus outside the dynamo itself, are all unaffected; but for the dynamo connected to the engine the advantage in first cost is at present with the belt connected machine, an advantage it will probably continue to retain.

The principal difference between the two classes affecting first cost is in the engine room space required. This is most marked, and is in all its bearings the most important characteristic of direct connection. Dynamos belted to engines on the same floor occupy from two to three times the floor space of direct connected combinations, giving the latter a considerable advantage in the first cost of land and buildings required. Where the engines are on the ground floor belted to dynamos on the floor above, the total floor space is about twice that required for direct connection. In this case the real estate covered is the same for both, but the building cost is increased, not only by the extra cost of the second story, but also by the much more substantial character of the work necessary to support the weight and prevent injurious vibration. The double story arrangement of station also presents special difficulties of its own with the belts and bearings, even where dynamos not larger than 100 horse power are used. Where the individual machines are of comparatively small power, as in an arc lighting station, the double story arrangement seems to give satisfaction. By completely separating the engines from the dynamos it also probably somewhat increases the cost of attendance. In every case the saving in first cost of land and buildings has a definite assignable value and can always be taken accurately into account to determine whether it is worth saving. It becomes a matter of fact and not a matter of opinion—a fortunate circumstance in an item which presents greater variations in value than any other single one of those which must be taken into account, varying between such extreme cases as the business portions of New York, where the annual rental of floor space is $5 per square foot, and the small town, where building lots can be bought outright for 5 cents a square foot.

It is surprising what can be done by direct connection in the way of concentrating power. In one plant the writer examined, 20 feet in length of an engine-room 18 feet wide and 8 feet high contained four 75 horse-power engines direct connected to four 50 K. W. dynamos and the switchboard for the whole plant, leaving comfortable room for the attendant to move about the machines and get at and remove any part of them.

Turning next to operating expenses. On our present assumption that equally good machinery is used in both cases, there seems no ground for any difference in the cost of repairs and small supplies, except such repairs as may be required to the belting itself.

In the cost of attendance, whatever difference there may be should be in favor of direct connection, owing to the greater compactness of the engine room plant obtainable by this method.

The weight of the rotating parts of dynamo and engine, the strain of the belt connecting them, and the thrust on the crank pin, will determine the resultant pressures and the consequent friction in the main bearings of a belt connected combination. With direct connection the weights are reduced by the absence of the armature pulley and the driving pulley on the engine; there is no belt strain, and the friction is that due to the reduced weight and the thrust on the crank pin, making the direct connected more efficient than the belt connected combination. What saving in fuel this means is a very interesting and important point which could be definitely determined only by an actual fuel test. But there is a most regrettable scarcity of any published engineering data on the subject, and the writer has been unable to find any records of tests which would determine this point. In the absence of such records we may attempt to form some idea of the possible fuel economy by calculation, but for a general consideration of the subject it helps us but little. In the engine the weights and the total belt strain are constant, and act each constantly in one direction at all loads, but the pressure due to the thrust on the crank pin changes its direction each revolution, varies with the load, and not only varies at different points of the stroke, but varies differently for different loads. Without indicator diagrams and without accurate dimensions and weights of the reciprocating parts of the engine, calculation becomes so approximate as to be of little use. Without these we must leave on one side the friction of the belt connected engine, and with it the whole friction of the direct connected dynamo and engine, which at most cannot be greater than for the belt connected engine alone, since the crank pin thrust is the same for both, the belt strain is absent in direct connection, and the weight of the rotating parts of the engine is but slightly increased by substituting the direct connected armature for the driving pulley on the engine shaft. A rough comparison of weights shows an increase of weight on engine bearings for direct connection, averaging 10 per cent for 8 sizes from 25 to 225 horse power, and 5 per cent. for 5 sizes from 40 to 125 horse power.

We may then take the friction of the belt connected dynamo as the minimum amount saved by direct connection. Now, this is the same actual power whatever the load on the dynamo may be. It depends on the weight and the total belt strain, which are the same at all loads; as the load increases, one side of the belt slackens just exactly as much as the other side tightens. Consequently the per cent. loss in the bearings increases as the load diminishes. If the saving by direct connection is at full load 2½ per cent. of the output of dynamo, it is at half load 5 per cent of the output of dynamo, and at quarter load 10 per cent. of the output of dynamo. Hence the total saving during a run depends, amongst other things, very much upon the average load on the dynamos during the run.

Reference has been already made to the dearth of published records of the performance of direct connected dynamos or of data concerning them. This is a matter for surprise in view of the early use and subsequent development of the type in Europe. But it is still more surprising that such a large amount of capital should have been invested in them in the United States during the last three years, with so little public notice of the reasons leading to their adoption, or the advantages expected to be gained by their use, and a complete absence of information as to what results have been actually realized.

Some of the Causes of Interruption to Telegraph Circuits.—II.

BY F. C. ROBERTSON.*

Crosses are not of such frequent occurrence as grounds, and in many cases occur through some material defect in the condition of the lines. Wires become crossed usually during the prevalence of a wind storm, which causes them to sway; at long stretches, especially where the wires happen to be slack, they more easily cross. Frequently crosses occur in consequence of a pin or tie wire breaking at an angle in the line, an insulator working loose and raising, or a pin being pulled out of cross-arm at a depression, allowing the wire to depart from its parallel position relative to the other wires. Crosses caused by a piece of small wire or other metallic object being thrown amongst the wires often occur, and on account of its obscurity the cross is with difficulty found by the lineman. I know of several instances where wires were found to be purposely connected with a piece of fine wire (evidently by persons bent on mischief) in such a manner that the fine wire could not be seen from the ground. Eventually in each case a galvanometer test was made and the cross approximately located; the lineman sent out to the supposed locality of the trouble was obliged to climb a number of poles before finding it.

When the nature of an interruption is such that the trouble does not remain on the wire constantly, but comes in and disappears again at intervals, it is called a "swing," and when the intervals are long and the length of time the trouble remains is short, the interruption, though of not so much consequence as regards impeding the working of the line, is more difficult and slow to locate than if the interruption were constant.

When two or more wires are crossed one of them can be cleared by opening the others at stations on each side of the cross. In case a through and a way wire are crossed it is customary to clear the through wire by opening the way wire at the stations between which the cross occurs in such a manner that said stations may have communication on the way with their respective terminals and intermediate offices. Such an arrangement is accomplished in the following manner: Suppose two wires, number 1 and 2, running west from terminal station A to terminal station D, are crossed between way stations B and C, of which B is east and C west of the cross. It is required to clear No. 2 (the through wire) and ground No. 1 (the way wire), so that B can work with A, and C with D, respectively. B opens the west end of No. 1 wire at the switchboard and grounds the east end with instrument in circuit east of the ground, C opens the east end of No. 1 at his switchboard and grounds the west end with instruments in circuit west of the ground; thus that part of No. 1 between stations B and C will be "dead," causing no interference with the working of No. 2. At the same time the circuit in the portions of No. 1 between A and B and between C and D will be closed by means of the ground connections.

Lightning coursing the wires during a thunderstorm has a strong tendency to do damage to the instruments, and were it not for the presence of that valuable arrangement called the "lightning arrester" (which forms an adjunct to modern cutouts and switchboards), many relays would be burned out. Before the lightning arrester was invented the custom was to cut out the instruments during a thunderstorm, but now it is considered quite safe to leave the instruments cut in, regardless of the storm, where the switchboard is provided with this protection, and it rarely happens that a relay is found to be damaged by lightning. The tendency of lightning to do damage is not confined to the instruments alone, poles on the line in the country being shattered and cross-arms splintered. In this connection it may be apropos to remark that the custom of modern line builders to provide the poles at intervals along the line with ground wires may be regarded as commendable; the arrangement appears to give good results in the capacity of lightning-rod protection to the poles.

Office main wires, especially if insulated with paraffined cotton covering, where allowed to rest in contact with a gas pipe or grounded object, are liable to become grounded by lightning penetrating the insulation and carbonizing it in its path, producing a conducting medium and creating a permanent connection between the main wire and grounded object.

During the brilliant display of luminous streamers exhibited in the heavens occasionally, and known as the Aurora Borealis, the telegraph circuits throughout the continent are more or less affected by earth currents, which become so severe at times as to entirely interrupt communication. These earth currents constantly vary both in intensity and polarity, making it impossible to keep the instruments adjusted on circuits having an earth return. It may be of interest to mention that some tests were made by Mr. William Finn, of the Western Union Telegraph Company, on a No. 6 gauge iron wire 213 miles long, extending from New York to Boston, during the magnetic storm of July 16, 1892, which showed that the abnormal current in the wire reached the strength of 133 milliamperes, and the maximum difference of potential of the earth at New York and Boston was 492 volts. Such a high voltage had not been observed during any previous storm. A wire can be worked during a magnetic storm by disconnecting the ground at each end and substituting a wire return instead, thus forming a metallic circuit. I beg here to state that a quadruple circuit arranged with a metallic return was successfully worked by the Canadian Pacific Telegraph Company between Toronto and Montreal during the magnetic storms of last year.

The foregoing mentions only a small portion of the troubles to which telegraph circuits are subject; to enumerate all would occupy much more space and time.

In conclusion I beg to mention a few conditions which, when complied with, have a tendency to prevent trouble to a great extent. The line should be constructed in a substantial manner, only first-class material being used. Poles should be sufficiently stout in proportion to their height, set well in the ground, placed close enough together to render the spans not too long, so as to well support the wires and to prevent them from crossing. At corners the stretchers should be much shorter, the poles well braced or guyed, double cross-armed and straight grained pins used. The wires should be stretched tight and the joints soldered. At crossings of other lines it is best to go above them, but if this cannot be conveniently done, the wires in passing underneath should have a good clearance and be protected by guard wires to prevent other wires from falling on them. At a low point in the line where there is an upward strain the pins should be nailed in, and loops or hooks secured to cross arm over each wire so as to catch it in case it should raise through an insulator coming off pin or a tie wire breaking.

All limbs of trees liable to come in contact with the wires should be removed. Special attention should be given to the wires in cities and towns to guard against crosses with electric light or railway circuits. Office cutouts and switchboards should be provided with lightning arresters, and the wires where they enter terminal offices be supplied with automatic line openers to act in case a cross with an electric or trolley wire occurs. For inside wiring it is preferable to use waterproof insulated wire, but if paraffined cotton covered wire be used it should not be laid in grooved boards, but secured by cleats and placed where it will be free from moisture, and where the insulated covering cannot become abraided. The batteries should be placed in a dry place, easy of access for frequent examination. Binding screws should be examined occasionally to see that they do not work loose. A vigilant and industrious lineman will prevent the occurrence of much trouble by frequent and careful examination of the lines in his charge, making repairs promptly when required and keeping the lines generally in such shape that the apparent liability of their becoming interrupted is reduced to the minimum.

(Concluded.)

* Read at the Convention of the Canadian Electrical Association.

Long Distance Telephony.

The American Telephone and Telegraph Company gave an exhibition of their long distance telephone lines on Thursday afternoon last to small party of guests who assembled at the Telephone Building in Cortlandt street at 5 o'clock.

Among those assembled to witness the exhibition were Dr. Von Helmholtz, Prof. Alexander Graham Bell, Dr. Herman Knapp, Miss Knapp Prof. Seth Low, Prof. Ogden N. Rood, Prof. Geo. E. Deschweinitz, and Mr. Edward J. Hall, Mr. Melville Egleston and Mr. F. A. Pickernell of the Telephone Company, besides some representatives of the electrical press.

A number of receivers were arranged so as to give each of the party a connection to the line. Connection was made with Boston, Chicago and Washington in turn, and conversations were held with the offices at those points. A cornet was also played which was heard through 500 miles of wire as distinctly as though it were in an adjoining room. The conversation with the headquarters of the Telephone Company at the World's Fair was held with perfect ease, speaking in an ordinary tone of voice. The exhibition proved of the greatest interest to the guests.

A railway based on the Greathead system of tunnels in London is now proposed for Brussels. It is to be worked by electricity and to run fifty feet below the surface. The first portion is to consist of a complete circle about four miles long, with double track, having eleven stations, and a future extension of a second circle of about two miles in length, with four stations; the two tunnels for the different sections will be quite distinct from each other; they run almost entirely below the public streets. The total cost of the first circle is estimated at $3,500,000, a less rate than the City and South London line, which cost $1,000,000 per mile. The elevators are to be operated by hydraulic power and will hold forty people.

A new form of trolley wheel designed for the purpose of keeping the wire free from ice and sleet during winter storms has been devised by John W. Clark, of Menands, N. Y. The spokes of the wheel are formed by radial openings cut through the flanges and also through part of the periphery of the hub, across which they extend and form a series of ice-breaking ridges at the bottom of the groove. This groove is of a size to fit the wire rather snugly, and between it and the flaring flanges of the wheel each spoke is provided with a sharp shoulder which aids in breaking part of the ice before the wire has actually made connection with the wheel, which may be made in two sections joined together.

Current Items.

It is estimated that the plant capacity of all the central electric lighting stations of London, England, reaches an aggregate of 850,000 eight-candle-power lamps.

Cape Town, South Africa, has an electric lighting station supplying 6,000 lamps, 400 of which are of the incandescent type. The water power of Tessina Brook, on Table Mountain, which has a fall of 1,350 feet, furnishes water to turbine wheels at the central station, a distance of four and a half miles. The plant has twenty-two miles of underground lines and fifty-six miles on iron poles.

An electric dredger is in successful operation in New Zealand, and has been found more efficient and more economical than steam dredgers. The use of the new dredger has enabled several changes of great benefit to be made in the ordinary system of dredging, and now operations can be carried on with ponderous machinery to a depth of sixty feet without trouble.

Electricity has either in imagination or in fact been pressed into many strange services, but we doubt whether it has performed anything more curious than it does in the case of the "tromometer," which is an instrument devised by a M. Quintard, of Angers, France, to determine the degree of shakiness or steadiness of the human hand. The "tromometer" consists of a knitting needle and a sheet of metal pierced with a series of gradually diminishing holes. One pole of a battery is connected to the knitting needle, the other to the draw plate, an electric bell being also in circuit. The "subject" has then to insert the needle through the holes in succession, beginning at the largest, until the amplitude of his "shakes" is such that he ends by touching the sides of the hole, a result which is announced to the world at large by the ringing of the electric bell. It is suggested that a "tromometer" would be a useful adjunct to the equipment of a competing rifleman; unfortunately for this idea, steadiness of hand and accurate shooting do not by any means go together, so that the indications of a "tromometer" would, as likely as not, be a cause of unnecessary discouragement.

The *Mail and Express* inclines to the belief that electric roads will prove highly beneficial to the farmer, and suggests possibilities in the matter of electric lighting, heating, etc., for country homes, which may yet be realized and relieve farm life of much of its dreariness and discomfort. That paper, in an editorial, says: "The tendency of country people to flock to the cities, and of inhabitants of the latter to live in the suburbs, proves that while mankind does not take kindly to the lack of social advantages in country life, there is a disposition to live where trees and grass grow, birds sing and flowers bloom, provided that this can can be done without a maximum of discomfort. We have before spoken of the popularity which country life will have when electric railroads run along the principal highways. That such roads will be constructed within a few years admits of no doubt. Already the trolley car connects cities and villages and gives traveling facilities to rural districts that until a year or two ago were far out of easy reach. As electric railroad building is perfected invention will still further cheapen its cost. When the farmer can reach a city or village in a few moments by electric car, and send his produce to market also by ready and rapid transit, much of the discomfort and loneliness of farm life will disappear. It is not impossible that the farmer may choose to live in a village and go to his daily employment on the farm as the New York banker or merchant goes to his counting room every morning. But the electric car is not alone to be the friend of the isolated and to give joy to the solitary. Many farms have running brooks within their limits. The electric power that can be obtained from these may be used to heat and light farm houses and to cook food and run farm machinery. Then country life would become delightful and we would cease to hear tales of the dwindling population of rural localities."

BOOK REVIEWS.

ARITHMETIC OF MAGNETISM AND ELECTRICITY. BY MORROW & REID. BUBIER PUBLISHING COMPANY, Lynn, Mass.

The above is the title of a useful little book which contains a great deal of practical formulæ and mathematical data on the subjects of magnetism and electricity. The book is eminently a practical one, its object being to present in concrete form such information as is specially useful in the commercial applications of electricity which constantly present themselves to the electrical engineer.

Following the general laws of the electric circuit are some chapters on the design of magneto-electric machinery of both the direct and alternating types, for which a number of rules are given not to be found collectively in any other work.

ELECTRICITY UP TO DATE. BY JOHN B. VERITY. F. WARNE & COMPANY, New York. Price 75 cents.

This is a popular treatise on the modern uses of electricity which makes no pretensions to technical merit, but contains a very readable account of the general applications of electricity in a style that will appeal to the general reader.

The general principles of the dynamo, storage battery, electric illumination, transmission of power and other subjects are explained in simple style, and a perusal of this work would dispel much of the mystery which is commonly imputed to the use of electricity by the public.

Legal Notes.

Two mortgages have been filed by the Jenney Electric Motor Company of Indianapolis. A mortgage for $9,984.18, to the Indiana National Bank, covers all the machinery, tools, etc., at present used in the plant. It is given to secure various notes. A second mortgage, given to the Capital National Bank, covers the same property, and is given to secure the payment of $4,000, in five notes of $800 each.

The appeal of the United States Electric Lighting Company in its case against the Edison Lamp Company for alleged infringement on a patented improvement in the process of manufacturing carbon conductors for incandescent electric lamps, was argued before Judges Dallas and Butler, in Philadelphia, on the 3d inst. Decision was reserved. The appeal was from the dismissal by Judge Acheson in the Circuit Court at Pittsburg.

Judgment for $6.732 has been entered against the Daft Electric Light Company in favor of Robert L. Belknap for money lent previous to July 24, 1891. Mr. Belknap was formerly president of the company, which was merged into the United Electric Traction Company three years ago.

A final decree, has been entered by Judge Grosscup, at Chicago, in each of the suits brought by the Edison Electric Light Company against the Illinois Electric Lamp Company and the Sunbeam Incandescent Lamp Company for an injunction and accounting. The decree in each case establishes the validity of the patent granted Thomas A. Edison in January, 1880, for the improvement of electric lamps. It further gives the complainant nominal damages and a perpetual injunction. The settlement is an amicable one, counsel for the several litigants agreeing to the form of the order of court.

The Short Electric Railway Company of Cleveland, through William S. Gummere, the counsel, has filed the bill in the suit against the Trenton Passenger Railway of Trenton, N. J., and asks for a restraining order to prevent them selling $1,000,000 worth of bonds, because they have not complied with an agreement made with the Short Electric Company. This latter corporation had $100,000 worth of notes discounted and sold the plant of the company, taking notes for the same, and they were to receive as collateral $600,000 of the bonds to be issued. They suspect that the bonds are sold or are about to be sold, and they want the company enjoined from disposing of them or any part of them until they give to the Short Electric Company the securities promised.

Judge Acheson, in the United States Circuit Court at Philadelphia, has granted a preliminary injunction pending the litigation in the suit brought by the Edison Electric Light Company and others against the Westinghouse Light, Heat and Power Company, John W. Mehargue and others. for alleged infringement on incandescent lights. The injunction is on the second claim of the plaintiffs' patent. The operation of the injunction, however, was suspended for twenty days.

Boston Notes.

The Haverhill and Queensbury and Gloucester Street Railways have withdrawn from the New England Street Railway Company, and are to receive back their own stock. No reason is assigned for this move, but it is believed that it is the outcome of a growing feeling against the consolidation project. People are beginning to appreciate that monopolies or movements tending in that direction are not always unmixed blessings.

As work becomes a little more abundant at the factories of the General Electric Company in Lynn, some of the old help are taken back at wages upon which a 10 per cent. reduction has been made.

Mayor Matthews is spoken of in Boston business circles as likely to become the successor of Mr. H. M. Whitney as president of the West End Railway. Mr. Matthews is an enterprising business man, who during his mayoralty has had many opportunities of learning a great deal about the needs of the traveling public in and around the city, and there are far less competent men than he who might be thought of for so responsible a position.

The electrical fountain erected on the Common at Lynn, as a bequest from a recently deceased public spirited citizen, was submitted to final tests on Friday evening, in the presence of something like 20,000 persons, and proved to be all that the contract called for. The city council then accepted the fountain as a gift to the city, the designer and builder, Mr. W. Blood, Jr., representing the Franklin Electric Company, Kansas City, receiving many congratulations on the completion of so artistic a piece of work, which is the most striking feature in Lynn's park system.

The Quincy and Boston Street Railway Company having completed its new power house at Quincy Point, is now furnishing the whole of its extensive system with current, which it finds is far more economical than renting power as heretofore from the Quincy Electric Light Company.

The past summer there has been an immense passenger traffic between Boston and the old historic town of Marblehead. Electric cars run all the way, and it has become quite a popular itinerary to take a car in Scollay Square, Boston, ride out to Lynn, there change cars and ride to Marblehead, through most charming country. In fact it may be said that the territory lying immediately to the north of Boston now traversed by the electrics is one of the most pleasant districts in New England.

The consolidation of the Thomson Electric Welding Company and the American Projectile Company, which we made mention of in our last issue, is reported to have been consummated. The company is to be known in future as the Thomson Electric Welding and Projectile Company and will have a capital of $1,000,000. The Welding Company was doing next to no business, but the Projectile Company has contracts with the United States Government that will keep it busy for several years.

General News.

What is Going on in the Electrical World.

St. Louis, Mo.—Electric ambulances are to be introduced here for use in street accidents.

Beloit, Wis.—G. L. Cole, of Ft. Atkinson, has bought the Beloit Electric Light Company's plant.

Dallas, Tex. The motive power of the Dallas and Oak Cliff Railway is to be changed from steam to electricity.

Orange, N. Y.—The trustees of South Orange have passed an ordinance permitting the electric road to use the street.

Tacoma, Wash.—The city council has passed an ordinance for rebuilding and repairing of the electric light station.

Warrensburg, N.Y.—The electric light plant, now being set up in this village, is expected to be in operation by November 1.

Piqua, Ohio.—The Miami Valley Electric Railway Company are considering the building of a line between this city and Minster.

Kingston, N. Y.—The Colonial City Electric Railway Company have announced their intention to begin construction work on their road at once.

Port Arthur, Can.—The electric road connecting the towns of Port Arthur, Fort William and West Fort William, eight miles long, is completed.

Flatbush, L. I.—The town board has awarded the contract for supplying the town with 300 electric lights to the Knickerbocker Electric Light Company.

Jacksonville, Fla.—Work has begun on an electric railroad from Jacksonville to Neptune. The line will be sixteen miles long, four miles of which are graded.

Rochester, Minn.—The Western Electric Company of Chicago will begin at once putting in the $20,000 electric light plant which has been contracted for by this city.

Youngstown, Ohio.—A proposition for the city to issue bonds for $100,000 to establish its own electric light plant is to be submitted to a vote of the people in November.

Lancaster, Pa.—Surveys are being made for an electric line between this city and Reading. The work of construction will be pushed forward as rapidly as possible after the survey is finished.

Middletown, N. Y.—The Traction Company have started work on the line to Goshen, and the proposition for the establishment of a pleasure park at some point on the route is receiving much attention.

Canton, Ohio.—The car house of the Canton-Massillon Electric Railroad was burned to the ground on the 3d inst., and nearly all the motors and trail cars of the company were destroyed, causing a loss of $100,000.

Buffalo, N. Y.—The Buffalo, Bellevue and Lancaster Railway, linking the new industrial town of Depew and the villages of Lancaster and Bellevue with Buffalo, is said to be one of the best electric roads in America.

Montreal, Can.—A. O. Granger, manager of the Auer Incandescent Light Company, has been suspended from the management of the company because he has been charged with defrauding the customs by false entries of goods imported from Vienna.

Oakland, Cal.—A certificate has been filed by the directors of the Alameda, Oakland and Piedmont Electric Railway Company of the action of the stockholders creating a bonded indebtedness of $350,000, which was voted by all the stockholders.

Hillsboro, Ill.—The St. Louis Interstate Electric Construction Company have put in an electric lighting plant here, under contract, and the light will be turned on about the middle of October. The contracting company owns about one-half of the stock.

Wellesley, Mass.—The selectmen of Wellesley have offered a franchise for an electric railway to run between Natick and West Newton to the Natick and Cochituate Street Railway Company, with the provision that it shall be in running order by July 4, 1894.

Poughkeepsie, N. Y.—L. F. Johnson, of this city, chief electrician of the N. Y. C. R.R., has been granted a patent on an electric battery which has been successfully used on the block signals of the road for the last six months, at a saving of $400 per month for each division.

Washington, D. C.—The officers of the Metropolitan road have announced their intention to use an underground electrical system on their lines if permitted to by Congress. They propose to adopt the Siemens & Halske system, which has been in successful operation at Budapest for three years.

Des Moines, Iowa.—Surveys have been made of the streets here with a view to the building of an elevated electric road, and a charter is to be presented to the council for its sanction. A local paper says the Westinghouse Electric Company is at the head of the improvement, and will build the road if it is ever built.

Goshen, Ind.—A receiver for the Indiana Electric Power Company has been asked for. The assets consist of about five miles of new street car track and general equipment. The aim of the company was to connect a belt of towns in Northern Indiana by electric lines. Assets and liabilities are said to be equal.

Plainfield, N. J.—A representative of the electric roads syndicate has been negotiating for the purchase of the Plainfield Street Railway, with the intention of extending it to Newark through intervening towns and to Bound Brook through Dunellen. It is proposed to run a freight car over the tracks as a local express accommodation.

Lowell, Mass.—The franchise of the Lowell, Lawrence and Haverhill electric street railroad through Bradford has expired while as yet the construction is not completed. In order to regain the franchise the company will have to obtain a new hearing. This cannot be had till spring and meanwhile operations on the road will have to be suspended.

Sacramento, Cal.—The Sacramento Electric Power and Light Company has closed a contract for furnishing the material and erecting the plant for transmission of power from their works at Folsom to Sacramento. The specifications cover the three-phase system of the General Electric Company and the two phase system of the Westinghouse Electric and Manufacturing Company.

Provincetown, Mass.—Representatives of an electric company have been here lately conferring with prominent business men as to the advisability of establishing an electric plant for a street railway and lighting the town. The project as outlined calls for an estimated outlay of $75,000. The electric company will invest $40,000 if the remainder of the stock be taken by people of the town.

Providence, R. I.—The Providence Electrical Works, a new corporation, is said to have secured an option on the Daboll Mill buildings at Elmwood. It is stated that the company will start with a capital of $400.000 and will absorb the Consolidated Electrical Works of Boston. Dynamos and a new wire, proof against poor insulation, are to be manufactured, and several valuable patents are to be developed.

Chicago.—The *Herald* states that O. W. Meysenburg, president of the Siemens & Halske Electric Company of America, is at the head of a syndicate organized to furnish rapid transit to the north side of this city and contiguous suburbs by a comprehensive electric railway system. The capital stock of the new concern will be about $5,000,000, and many of the influential and wealthy property owners of the north side have pledged already sufficient subscriptions to assure the capital.

Philadelphia—In the Kensington section of this city the people celebrate the opening of the fall trade by musical parades and street illuminations. The festivities this year began on Wednesday evening, and closed on Friday evening of last week. The illuminations extended all along Frankford avenue. Fifty red and white arc lights in the centre of the street threw out their brilliancy at intervals of 200 feet apart, lighting up the gayly arranged store windows, nearly all of which were also illuminated by their private electric lights. All the extra electric lights for the occasion were donated by the Frankford Avenue Merchants' Electric Light Company. Besides these, thousands of Chinese lanterns, lit with candles, were strung along the house fronts, while at every available place floated the American flag.

A New Alternating Current Lamp.

The Electric Construction and Supply Company the Makers.

Always up to date in supplying what the people want in the way of arc lamps, the Electric Construction and Supply Company of New York have just placed on the market a new lamp for alternating circuits, either 30 or 50 volts, secondary. Two sizes are made at present, 10 and 14 amperes.

The chief points of merit claimed for the lamp are its simplicity of construction, entire freedom from complicated mechanism, lightness and durability—all important features for a successful arc lamp. Prices are reasonable, and the lamp can be supplied in various highly ornamental designs, if desired.

The World's Fair a Success, but it Will Soon Close its Gates Forever.

The grandest exhibition of our time, and possibly for many generations to come, will soon be brought to an end.

There remains but one month in which to visit this marvelous gathering of all the World's Productions, and everybody should strain a point to go to Chicago.

The railroad fare heretofore has been considered a hindrance to all classes, but this has all been changed, and on the following days in October the West Shore Railroad will run high-class excursions on its fast express trains in through cars at one-half its lowest fare, i. e., $17.00 from New York to Chicago and return, and proportionately lower rates from points along its line. These magnificent excursion trains will be in charge of an agent whose duty it is to care for the interests of the company's patrons en route, to furnish detailed information as to accommodations obtainable in Chicago, and to point out the historic points along the grand old Hudson and through the picturesque Mohawk Valley.

These trains will leave Franklin street, New York, at 10:00 A. M., and West Forty-second street at 10:10, as follows: Saturday, October 14; Thursday, October 19, and the last, Monday, October 23.

C.-S. Automatic Magnetic Cut-Out.

A magnetic cut-out so constructed as to withstand the rough usage incident to street car service; one that is easily and conveniently adjusted to open only upon an overload beyond that which the motor at times is expected to carry; one that is compact and simple in construction and which can be supplied at a price that is not prohibitory, is something that was waited for a long time. A magnetic cut-out answering these requirements was first produced by Mr. H. B. Cutter, of Philadelphia, and is now numbered among the C.-S. specialties.

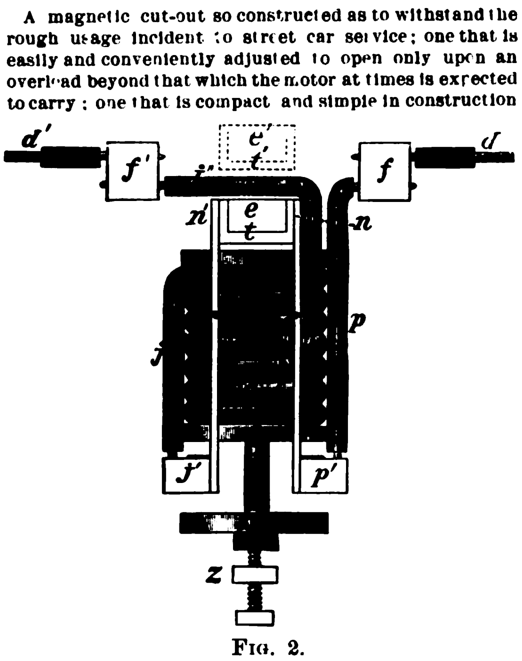

FIG. 2.

Fig. 1 shows this device complete and in position. The iron case which encloses it is hermetically sealed against the weather by means of a packing of rubber between the case proper and its hinged cover which is firmly seated and held in place by the screw lock *a*. The conductor wire *d* enters the case through hard rubber bushings *c* on either side. The dimensions of the case are as shown, and it is fastened in place by means of four lugs, two on either side at the bottom. The act of opening the case breaks the circuit on the trolley side, thus insuring safety in handling and adjusting the mechanism. Figs. 2 to 8, following, fully describe the device in full.

Fig. 2 is a diagrammatic plan showing details of this device. A fuse of low blowing capacity, compared to the maximum current the magnetic switch is intended to pass, is placed in shunt between the two plates of the switch, so that when current is broken at the switch terminals the fuse carries the current for a short period of time.

In street railway practice circuit is from trolley terminal d, through clamp f, conductor p and clamp p' to switch plate n; thence through bridge t, to plate n'; thence through clamp j', conductor j, coil $q\ q$, conductor j'' and clamp f' to controlling switch terminal d'. A small portion of the current passes in shunt from point m on plate n to point m' on plate n' through fuse y. For a 500 volt circuit this fuse would ordinarily be of a rated capacity of 5 amperes.

When a normal current is passing, the pole plate r of the plunger is in position as shown. When the overload comes the plunger is drawn up into the coil, driving the switch bar and bridge into position shown by the dotted lines $e'\ t'$ and breaking the circuit at $n\ n'$. The entire current is carried by the fuse for a period of time sufficient for the bridge to reach a safe position—then it "blows," provision being made against the formation of an arc between m and m'.

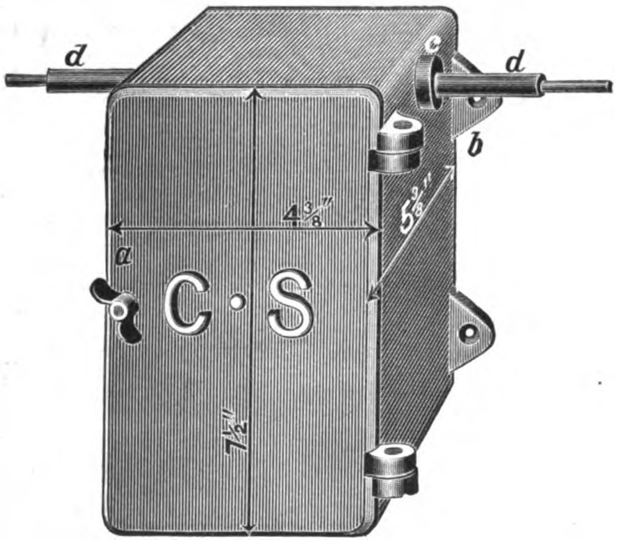
Removal Notice.

Mr. W. F. B. Pratt, who is doing a lively business taking orders for the renewing of Edison lamp for the Boston Incandescent Lamp Company, has move his offices to No. 40 Cortlandt street.

COMMERCIAL PARAGRAPHS.

The Iona Manufacturing Company of Boston, which manufactures special lines of electrical supplies, reports business as improving briskly. They have recently started quite a number of fresh hands to enable them to handle with despatch some very large orders for ceiling rosettes, etc., from the West.

The W. S. Hill Electric Company, Boston, has just secured a splendid contract for several of their high-grade electrical specialties, which contract has compelled the company to increase its staff of men, who will be fully employed for several months on this contract alone. This well known firm enjoys an enviable reputation for the high-grade quality of its goods, and through all the financial depression has kept busy right along. Its large and well equipped factory is now rushing.



C.-S. AUTOMATIC MAGNETIC CUT-OUT. (FIG. 1.)

The New England Electric Heating Company has leased a large factory at Milford, Conn., where it will manufacture its various devices for which there is a constantly growing demand. At the present time the company is way behind its orders.

The Phillips Insulated Wire Company of Pawtucket, R. I., has just declared a dividend of 2 per cent. This company has become so prosperous, and is now doing so large a business, that it is building a large brick factory and equipping it with every modern type of machine, so as to be enabled to handle its growing volume of business.

Notwithstanding the general depression, the Boston Braid Company finds that its enlarged and extended facilities are none too much for the excellent demand it is enjoying for its highly finished silks for lamp filaments.

The Shawmut Fuse Wire Company of Boston have issued a neat pamphlet descriptive of their specialty, which embraces an instructive chapter on "Fuse Wire and its Uses."

The splendid exhibit which the New England Butt Company of Providence, R. I., is making at the World's Fair bringing substantial results, for at the present time here is a brisk demand for its high-grade braiders, etc. The foreign visitors to the Fair who are engaged in the wire and cable business have had many words of praise for this company's machines, and are showing their appreciation by placing some good orders for same.

The Frink Improved Reflectors, which have for many years been recognized as the standard for use in connection with incandescent lighting work, received the well-merited tribute of the award at the World's Fair.

Among orders received by A. L. Ide & Son, of Springfield, Ill., during the last ten days are the following: One 100 H. P. Ideal engine for the Ludington Building, Chicago; one 125 H. P. engine for the Hoopeston Canning Company, Hoopeston, Ill.; three 175 H. P. Ideal tandem compound engines for the new Stock Exchange Building, Chicago, and two 125 H. P. and one 100 H. P. Ideal engines for the Southern Hotel, St. Louis. The Stock Exchange and the Southern Hotel engines are all to have General Electric Company multipolar armatures directly attached to their crank shafts, the Stock Exchange engines driving 100 K.W. machines and the Southern Hotel engines driving 50 K. W machines.

INCORPORATIONS.

The Sacramento County Irrigation Company, San Francisco, Cal.—to operate water rights and works, generate electric and other power and deal in same, etc. Capital stock, $1,000,000. Promoters: J. A. Merrill, A. R. Dow, Oakland; R. W. Button, D. T. Thomas. W. B. Thomas, San Francisco.

The Columbian Gold Mining Company, San Francisco, Cal.—to deal in and operate mines, mineral lands, mills, machinery, electric light and power plants, etc. Capital stock, $1,000,000. Promoters: J. A. Merrill, A. R. Dow, Oakland; D. R. Thomas, R. W. Button, W. B. Thomas, San Francisco.

The Junction City Electric Light, Power and Milling Company, Junction City, Kan.—to furnish electricity for light, heat and power, etc. Promoters: John K. Wright, A. L. Barnes, Junction City; James S. Gibson, Kansas City, Kan.

C. C. Warren Electric Company, at Chicago—for the construction of steam railways and electric light plants. Capital stock, $2.000,000. Incorporators: Holbert B. Warren, W. W. Wheelock and George B. Shattuck.

The South Mountain Railway and Electric Light and Power Company, Boonsboro', Md.—to build an electric railway from Boonsboro', to Keedysville (three miles) and to furnish electric light and power to both towns. Incorporators: George W. Jacobs, Jr., of Philadelphia; Theodore E. Bowne, of New York; Edgar L. Miller and Elmer J. Smith, of Frederick; Charles J. Young, C. E. Shafer and George A. Davis, of Boonsboro'.

The Mecosta Electric Company, Big Rapids, Mich. Capital stock, $25,000.

The Mt. Pleasant Gas and Electric Light Company, Mt. Pleasant, Iowa—to operate a light and power plant at Mt. Pleasant. Capital stock, $72,000. Promoters: Henry Ambler, Geo. H. Spahr, H. E. Snider, Mt. Pleasant.

The Automatic Wind Motor Company, Blasdell, Erie County, N. Y.—to manufacture wind motors, pumps and pumping appliances, and electrical machinery to be used in connection with such motors. Capital stock, $100,000. Directors: David Berry, Big Tree, Erie County; A. R. Meldrum and Henry L. Erisman, Buffalo; Charles M. Nichols, Jamestown, Chautauqua County; Peter Berry, Plumer, Pa.

The California Mutual Investment Company, Los Angeles, Cal.—to furnish electric light and power, etc. Capital stock, $200,000. Promoters: T. K. Wilson, S. A. Butler, I. W. Adams, Wm. A. Elderkin, A. M. Anthony, Los Angeles.

The Wabaska Electric Company, Wymore, Neb.—to construct electric light, power and electrical plants in Nebraska. Capital stock, $25,000. Promoters: Alex. Stewart, S. D. Rengler, H. C. Van Buskirk.

The Oyster Bay (N. Y.) Electric Light and Power Company reports that its capital stock has been increased from $5,000 to $15,000. It has no debts.

The Wenstrom Electric Company, at Baltimore, Md.—to take the place of the Wenstrom Consolidated Dynamo and Motor Company and operate the plant of the defunct concern at Calverton, Md. Capital stock, $1,000,000. Incorporators: Joseph P. Smith, Ferdinand C. Latrobe, John M. Denison, Robert Rennert and John E. Semmes.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED SEPTEMBER 19, 1893

ELECTRIC RAILWAYS AND APPLIANCES.

505,204. Current Converter for Electric Railways. William Lawrence, New York, N. Y., assignor to the Lawrence Electric Company, same place. Original application filed Aug. 17, 1892. Divided and this application filed June 27, 1893.

505,370. Electric Railway Trolley. Elbert R. Robinson, Nashville, Tenn. Filed March 7, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

505,097. Electric Light Fixture. Benjamin F. Flint, Cincinnati, Ohio. Filed June 17, 1893.

505,098. Revolving Electric Light. Benjamin F. Flint, Cincinnati, Ohio. Filed July 5, 1893.

505,183. Electric Arc Lamp. Arthur S. Atwater, Cleveland, Ohio. assignor to the Atwater General Electric Company, same place. Filed Jan. 16, 1893.

505,233. Electric Arc Lamp. Charles Schmidt, Chicago, Ill., assignor of one-half to Pancratus Friedrich, Jeanette, Pa. Filed Jan. 10, 1893.

505,241. Electric Lighting System. Addison G. Waterhouse, Hartford, Conn. Filed Nov. 28, 1892.

505,326. Lamp. Delmar D. Pinkham and Frank E. Lewis, Longview, Tex. Filed July 21, 1892.

505,351. Electric Headlight. Edgar A. Edwards, Cincinnati, Ohio. Filed Aug. 15, 1893.

505,383. Electric Arc Lamp. Sigmund Bergmann, New York, N. Y. Filed July 19, 1893.

505,422. Electric Lamp Socket. John M. Gardner, Jr., Pittsburg, Pa., assignor of one-half to Peter Weber, same place. Filed July 1, 1893.

DYNAMOS, MOTORS, ETC.

505,184. Dynamo-Electric Machine. Arthur S. Atwater, Cleveland, Ohio, assignor to the Atwater General Electric Company, same place. Filed Jan. 16, 1893.

505,207. Automatic Regulator for Dynamo-Electric Machines. Orvis P. Philbrick, Somerville, Mass. Filed April 2, 1892.

505,247. Armature for Dynamo-Electric Machines or Motors. Walter T. Kosinski, New York, N. Y. Filed May 5, 1893.

505,396. Electric Motor. Ernest R. Esmond, New York, N. Y. Filed Aug. 15, 1893.

BATTERIES.

505,392. Electric Primary Battery. Theophilus Coad, London, England. Filed Nov. 10, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

505,087. Telephone. Joseph B. S. Booth and Ernest J. Falconer, Manchester, England. Filed Jan. 31, 1893.

505,170. Telephone Switch. Thomas W. Ness, Montreal, Canada. Filed May 22, 1893.

505,308. Telephone System. William W. Davis, California, Mo., assignor to himself, Walter Lander and Frank B. Lander, same place. Filed Dec. 30, 1892.

SIGNALS AND SIGNALING APPARATUS.

505,419. Block Signal Apparatus. Johann H. Frischen, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 13, 1893.

505,420. Block Signal Apparatus. Johann H. Frischen, Berlin, Germany, assignor to Siemens & Halske, same place. Filed May 18, 1893.

MISCELLANEOUS.

505,106. Lightning Rod. Nathaniel D. C. Hodges. Plainfield, N. J., assignor to the American Lightning Protection Company, Sioux City, Iowa. Filed Dec. 17, 1890.

505,123. Insulator Pin. James J. O'Neill, Boston, Mass. Filed April 14, 1893.

505,125. Process for Manufacturing Electrodes. Carl Pollak, Frankfort-on-the-Main, Germany. Filed April 19, 1893.

505,135. Rail Heating Device. Charles S. Smith and Elmer E. Knowles, Spokane, Wash. Filed April 24, 1893.

505,188. Multiple Switchboard Apparatus. John J. Carty, New York, N. Y., assignor to the Western Electric Company of Chicago, Ill. Filed Feb. 2, 1889. Renewed Oct. 16, 1891.

505,200. Indicator Mechanism for Type-Setting Machinery. John Hooker, Beccles, England. Filed Jan. 16, 1893.

505,215. Cleat for Holding a Plurality of Insulated Electric Wires. Elisha W. Buffinton, Fall River, Mass., assignor of one-half to Albert F. Dow, same place. Filed March 27, 1893.

505,243. Recording Voltmeter. William H. Bristol, Hoboken, N. J. Filed April 17, 1893.

505,268. Electrical Metal Working. George D. Burton, Boston, and Edwin E. Angell, Somerville, Mass., assignors to the Electrical Forging Company of Maine. Filed Feb. 27, 1892.

505,270. Electric Door Operating Apparatus. Oliver H. Hicks and Robertus F. Troy, Chicago, Ill.; said Troy assignor to said Hicks. Filed May 15, 1893.

505.271. Electric Door Operating Apparatus. Oliver H. Hicks and Robertus F. Troy, Chicago, Ill.; said Troy assignor to said Hicks. Filed May 15, 1893.

505,293. Printing Telegraph for Cash Recording Systems. Henry K. Hess, Syracuse, N. Y. Filed Sept. 5, 1892.

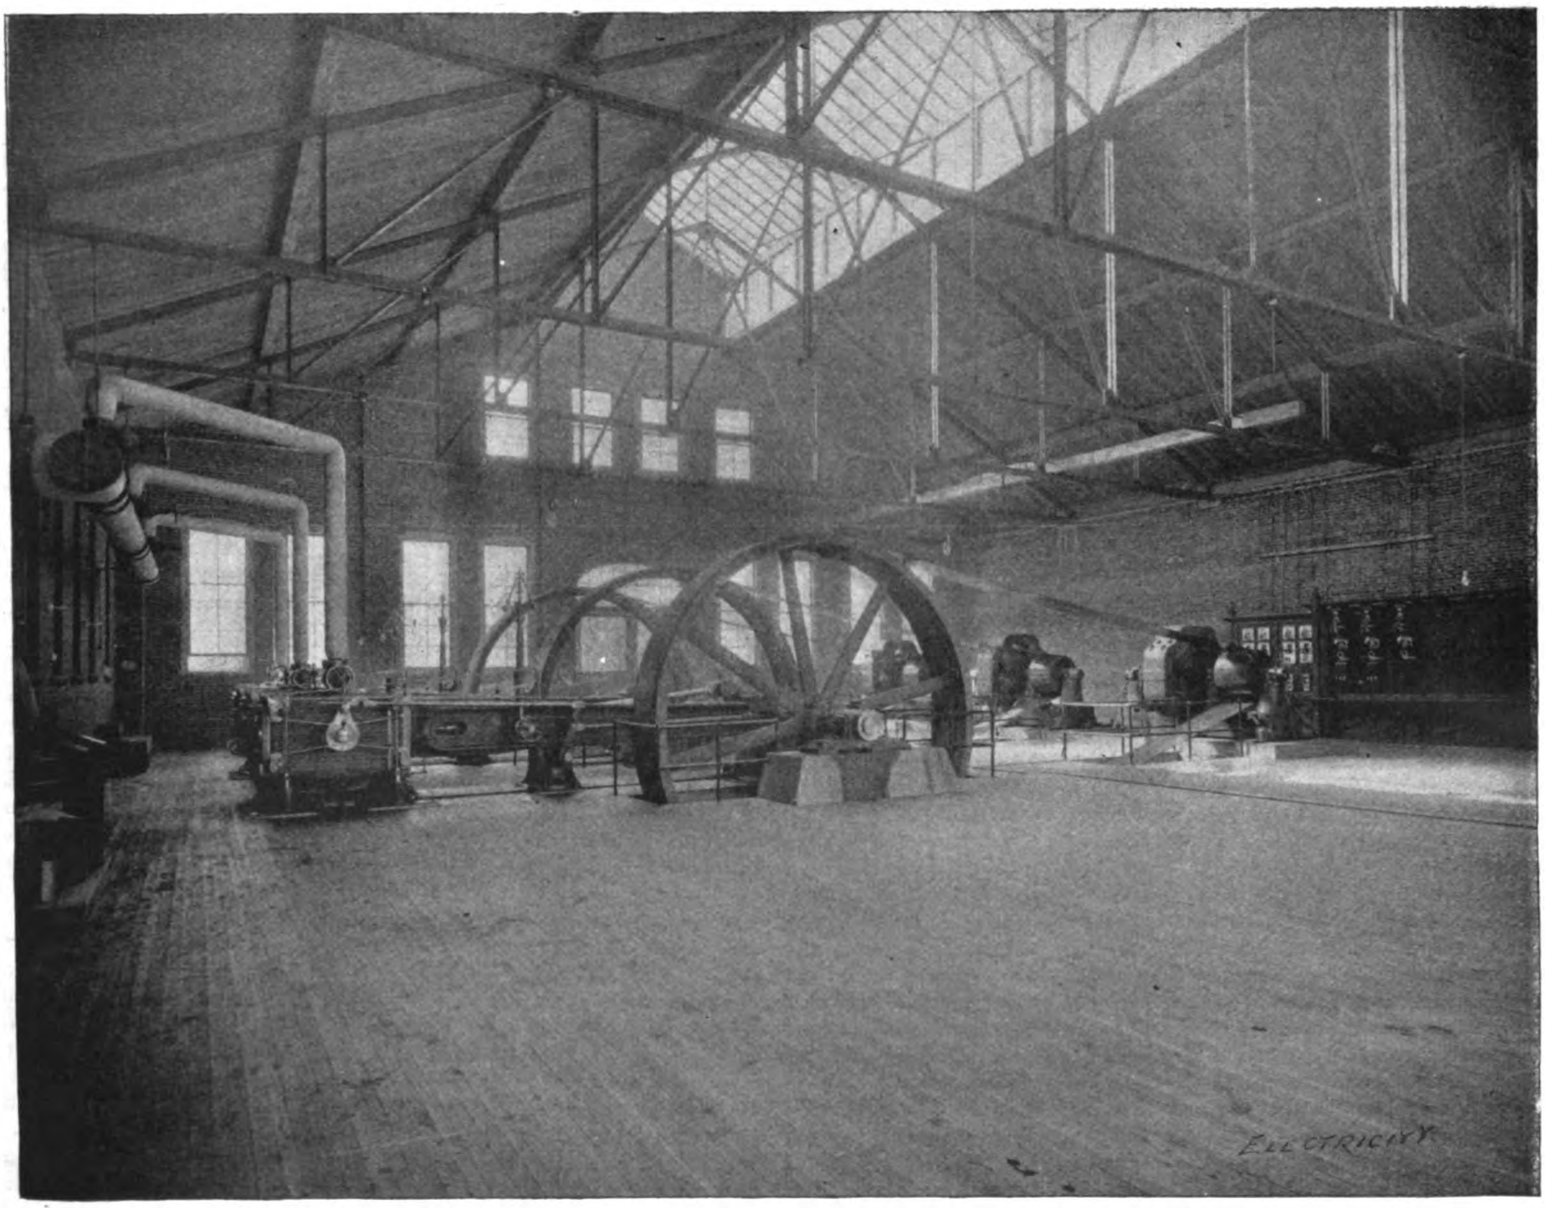
505,346. Electric Illuminated Sign. Henry A. Bierley, Lexington, Ky. Filed Feb. 8, 1893.

505,393. Electro-Medical Air Injector. James Dawey and Frank M. Cattern, Denver, Colo. Filed Aug. 7, 1893.

505,414. Balloon for Observing Distant Objects. Chas. A. Smith, San Francisco, Cal. Filed May 11, 1893.

ELECTRICITY.

VOL. V. NEW YORK. OCTOBER 18, 1893. CHICAGO. No. 14



DYNAMO AND ENGINE ROOM, ST. CLAIR STREET RAILWAY, CLEVELAND. (SEE PAGE 162.)

A New Electric Railway for Cleveland.

The St. Clair street railway line in Cleveland has just been equipped with electricity, and we present herewith a description and illustrations of the plant, which has just been completed.

The power house for this road is built as an addition to the Superior street cable railway building. It is constructed of pressed brick with an iron and slate roof. The engines, shown in the Frontispiece, are three in number and have a capacity of 250 horse power each. They are single cylinder machines built by the Bass Foundry and Machine Works of Fort Wayne, Ind.

The engines are belted direct to three 270-horse power generators of the usual 4-pole railway type.

The switchboard, shown in Fig. 1, is built with an oak frame in which slate panels are set. On one end of this board are placed the instruments and switches belonging to the dynamos. These are all of the Thomson-Houston make. From the other end of the switchboard four feeders are led out to different points on the road, and each feeder is equipped with a lightning arrester and automatic cutout and switch of the Westinghouse type.

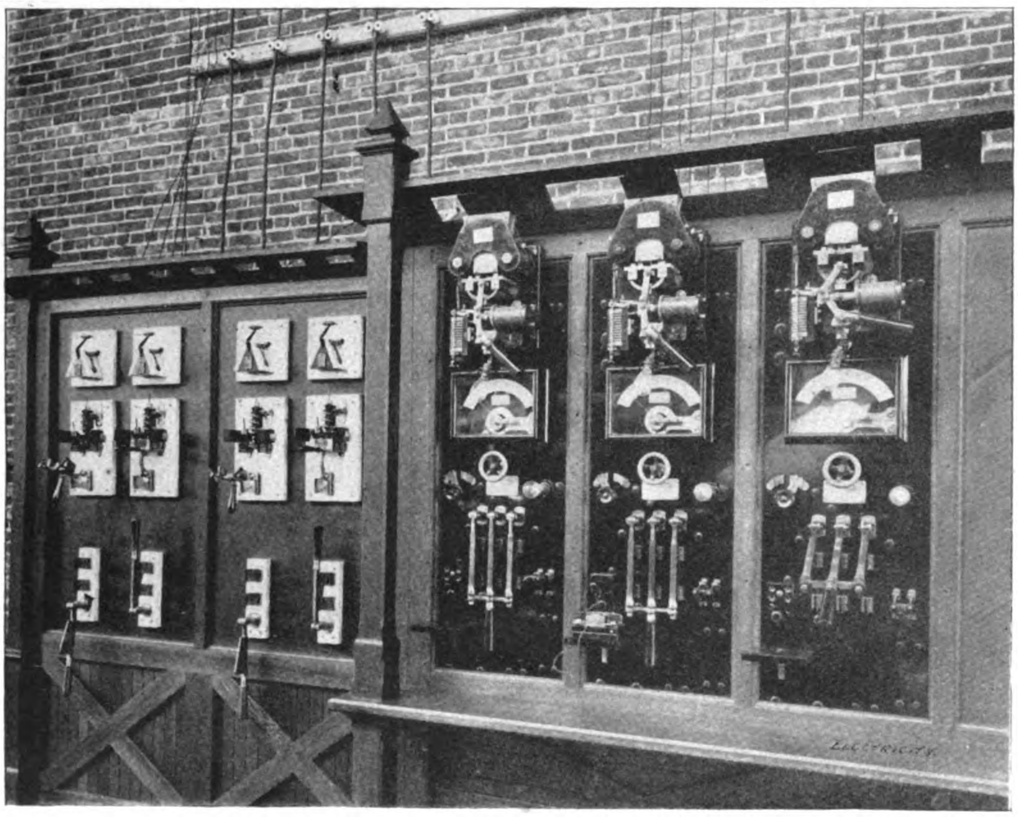


FIG. 1.

The boiler plant of the cable railway consists of four Babcock & Wilcox boilers aggregating 1,100-horse power, and two 750-horse power Sterling boilers were added to this battery for the use of the electric road. The piping on the boilers is arranged so that any boiler may be used to supply power to either plant.

Oil is used for fuel in this plant, which is fed to the boilers through Reid burners. The piping throughout the station is covered with mineral wool and all sizes above 6 inches are flanged and riveted. Jenkins valves are used.

The roadbed consists of 12½ miles of single track on which 90 pound girder rail is used. This rail is 9 inches deep and is laid to standard gauge. The splices are thirty-eight inches long and use twelve ¾ inch bolts. Lake gravel is used for ballast.

The poles on about 3,000 feet of the road are of iron, and the remainder are octagonal wooden poles. The trolley line is divided into four sections, two on each side of the power house, which is located at about the middle of the line.

The cars are equipped with Short motors and multiple series controllers. The cars were built by Jones & Brownell, and are supplied with Dorner & Dutton trucks.

The management of this road, which has been recently completed, is in the hands of Mr. F. M. Faber, M. E.

Various Uses of the Electrostatic Voltmeter.

BY DR. T. SAHULKA.*

In the paper I intend to read before you I shall communicate some measurements made with an electrostatic voltmeter, especially the measurement of the capacity of condensers which are inserted in an alternating current circuit.

The great advantages of the electrostatic voltmeters in comparison with the other voltmeters, especially when using alternating currents, are well known. They require almost no current; the readings are not influenced by the temperature and by the neighborhood of magnetic bodies; by enclosing the electrostatic voltmeter in a metallic shell, it can also not be influenced by electric bodies in the neighborhood. The excellent instruments invented by Sir W. Thompson are well known. They contain a fixed and a movable system. In the multicellular type the fixed system is formed by a number of pairs of quadrants. The movable system consists of an equal number of needles placed between the quadrants and suspended on a thin wire (Fig. 1). If the difference of potential between two points is to be measured, the movable system and the metallic shell enclosing the instrument are connected with the one point, the fixed system with the other point. The movable system is thus deflected; a pointer, which is connected with the system, enables direct reading.

The electrostatic voltmeters are generally used only for measuring potentials. They can also be used for other purposes.

I wished, firstly, to examine how small is the current traversing such an instrument when measuring an alternating potential difference with it, and how great is the capacity of the instrument. That could not be done with any of the known methods, the charging current and the capacity being very small. The instrument I used was a multicellular voltmeter of Sir W. Thompson, range 80 to 400 volts; but the scale intervals are only between 120 and 220 volts, large enough to enable an exact reading. In order to get a suitable difference of potential, I transformed the alternate current supplied by an electric central station, having 2,500 full periods per minute, and a potential difference of about 105 volts, in the ratio of 1: 2 by a step-up transformer. The potential difference e between the terminals of the secondary, was now measured with the electrostatic voltmeter. Afterwards a great graphite resistance r, having no capacity and no self-induction, was connected in series with the instrument. The voltmeter indicated now a smaller potential difference e_1. As the voltmeter is a small air condenser, the phase of the potential difference e_1 corresponding to the same must be 90° behind the phase of the charging current c, whilst the potential difference e_2, corresponding to the resistance r, coincides in phase with the current c (Fig. 2). We have therefore

$$c = \sqrt{e_1^2 + c_2^2}.$$

c and e_1 being known, e_2 can be determined; we know therefore the charging current

$$c = \frac{e_2}{r}.$$

If the number n of periods per second be known, we can also count the capacity K of the voltmeter, for the equation must hold:

$$c = 2 \pi n e_1 K. \quad . \quad . \qquad (1.)$$

The alternating current had 2,500 periods per minute; therefore we have to substitute:

$$p = 2 \pi n = 262.$$

In Table I are contained the results which had been obtained with the voltmeter mentioned before. The values in the column r are given in megohms, the values of c e_1 e_2 in volts; the unit of c is one-millionth of an ampere; the unit of K is one-millionth of a microfarad.. In the last column, r_1, are given the relative impedance of the voltmeter expressed in megohms.

TABLE I.

r	e	e_1	e_2	c	K	r_1
11.05	207.2	195.3	62.2	6.26	122.	31.2
20.78	207.6	177.1	108.3	5.21	112.	34.0
33.16	207.6	154.6	138.6	4.18	103.	37.0
41.90	207.9	140.3	153.4	3.66	99.6	38.3
52.40	208.0	124.4	166.7	3.18	97.6	39.1

The results are represented graphically in the diagram (Fig. 3). The abscissæ represent the number of volts indicated by the instrument; the ordinates of the curve c represent the charging current, the unit being equal to one ten-millionth of an ampere; the ordinates of the curve K represent the capacity K, the unit being equal to one millionth of a microfarad. It is striking how small the charging current and the capacity of the instrument is. The capacity is greater for higher values of e than for lower values, as the movable system of the voltmeter is more deflected towards the fixed system. If there is no potential difference between the terminals of the instrument, its capacity has its smallest value. Should the instrument be arranged in such a way that the movable system would always be brought back to its zero position by the aid of a torsion head, then the capacity of the instrument would be constant, the scale could then be spread over the whole circumference, whilst in the present shape the deflection is always less than 90 degrees.

If the diagram (Fig. 3) would have been plotted for any electrostatic voltmeter, this instrument could be used for measuring great resistances, which have no capacity and self-induction, and are of the same range as the impedance of the instrument. The resistances have to be arranged in series with the voltmeter.

---

*Read before the International Electrical Congress, Chicago.

As the alternating current which traverses an electrostatic voltmeter is exceedingly small, this instrument might be usefully employed for the *indirect measurement of the intensity of the magnetic field of converters or electro-magnets, which are excited by alternating currents.* It is only necessary to wind around the core a sufficient number of turns of thin wire, and to connect its ends with the voltmeter. As the instrument requires almost no current, the magnetic field of the core is not influenced by measuring it with the voltmeter.

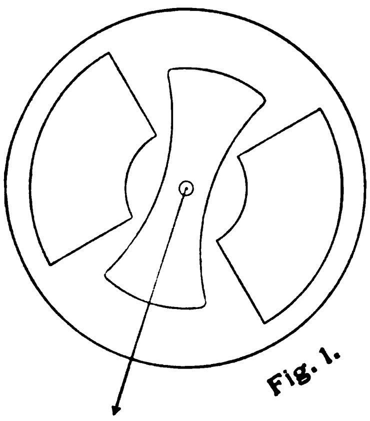

Fig. 1.

The electrostatic voltmeter can also be applied very usefully for *measuring the capacity of condensers, which are inserted in an alternating current circuit.* I used for this purpose a method which is similar to that applied by Toubert for measuring the coefficients of self-induction. I placed in series with the condenser a non-inductive resistance r, its capacity being negligible. The resistance r may be of the same range as the impedance of the condenser. For every condenser a suitable resistance r can be chosen. With the electrostatic voltmeter there may be measured the total difference of potential e, then e_1, corresponding to the condenser, and e_2 corresponding to the resistance r. If the condenser is an air-condenser, and if the frequency of the alternating currents is low, then a rectangular triangle can be designed (Fig. 2), of which the hypotenuse is equal to e, and the sides equal to e_1, e_2. Now, if the condenser has a solid dielectric, then e is no longer 90 degrees behind in phase with the charging current c, but by a smaller angle α (Fig. 4). The potential difference e_2 coincides in phase with the current c. The condenser placed in the alternating current circuit absorbs energy, for which loss Mr. Steinmetz has found the law that loss of energy causes a heating of the condenser. We must conclude that the capacity of the condenser is not constant, but varies in every moment during one period like the coefficient of self-induction of an electro-magnet. In the same way, as special definitions are chosen for the intensity of currents and the electromotive force in alternating current circuits, we have also to define what may be considered as the capacity K_1 of a condenser which is inserted in an alternating current circuit. That could be done in the following way:

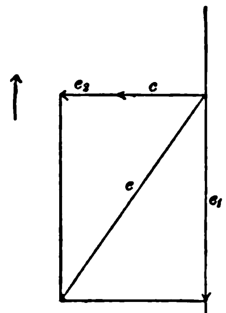

Fig. 2.

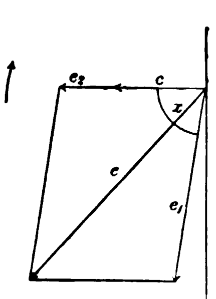

Fig. 4.

The apparent resistance (impedance) of the condenser, that is, the ratio of e_1 to e, must be equal to the reciprocal of $2\pi n$ times K. The definition agrees with the formula 1. In Table II are given some results obtained with condensers having paraffined paper as dieletric. K is the capacity measured with a continuous current electromotive force in the well-known way, by observing the deflection of a galvanometer needle, the unit of the values K being one microfarad. The resistance r placed in series with the condenser is given in ohms. $e\ e_1\ e_2$ are the observed potential difference in volts; the unit of the current c is one ampere; the value of K is equal to $\frac{c}{2\pi n e_1}$, and could be taken as the capacity of the condenser when placed in the alternating current circuit; the unit of K_1 is also one microfarad. There was calculated also the angle of lag α according to the formula

$$\cos\alpha = \frac{e^2 - e_1^2 - e_2^2}{2\,e_1\,e_2}$$

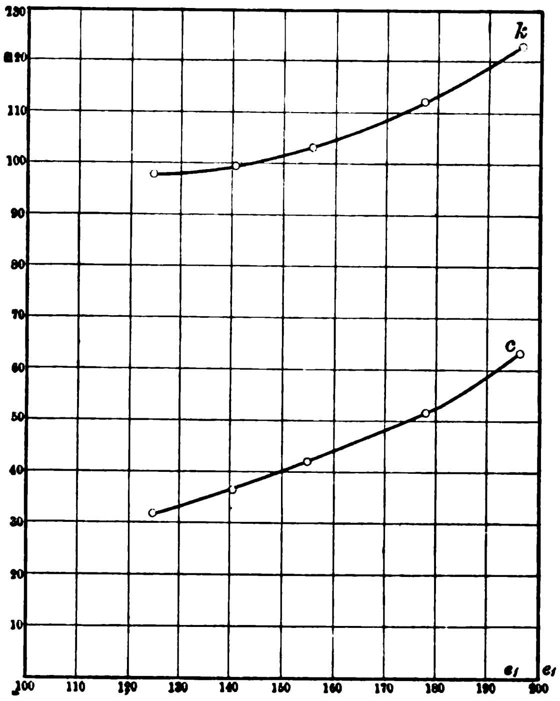

Fig. 3.

and the energy absorbed by the condenser, according to the well-known method of Prof. Ayrton. This energy is named W and is given in watts. $W = e_1\ c \cos\alpha$.

TABLE II.

K	r	e	e_1	e_2	c	K_1	α	W	c	$\frac{1}{2\pi n K_2}$	K_2
1.004	4000	206.9	147.8	135.2	0.0328	0.873	86° 09′	0.336	293.7	4363	0.875
"	5000	206.8	132.0	149.2	0.0298	0.862	85° 31′	0.308	346.6	4416	0.864
"	6000	207.5	120.1	161.1	0.0269	0.855	86° 02′	0.224	309.1	4454	0.857
"	7000	207.4	107.5	170.0	0.0243	0.863	85° 59′	0.183	309.7	4413	0.865
0.514	9000	207.6	139.7	145.3	0.0161	0.440	87° 30′	0.137	527.9	8661	0.441
2.618	2000	207.1	129.8	152.5	0.0763	2.244	85° 58′	0.697	119.7	1697	2.249

In the table are also calculated the values of c and K_2.

The condenser, having a solid dielectric, behaves like an air-condenser, having the capacity K_2, and being connected in series with a resistance C. The quantity K_2 may be considered as the effective capacity of the condenser. I deem it useful to calculate the effective capacity K_2 of a condenser and the loss of energy, which is caused at a certain difference of potential and a given number of full periods per second.

As the value of the cos. α is calculated from a difference of nearly equal numbers, it is not quite exact therefore; also the value of the absorbed energy is not very exact. Should the value of α and the absorbed energy be measured more exactly, every single experiment has to be repeated several times in order to get average values. The table II has been calculated only from single experiments. If the alternating generator runs with a constant speed, the variation of K_2 is less than one per cent.

If we compare the values of K_2, corresponding to the three condensers, taking an average value of the four first experiments, we find the same ratio (1 : 0·51 : 2·60) that have the values of K; *but the values of K_2 are less by 14 per cent. than the corresponding value of K. We conclude from that that the condensers with a solid dielectric have a smaller capacity when placed in an alternating current circuit than when they are charged with a continuous current electromotive force;* only the air condensers will not show such a difference. The cause of this remarkable fact is to be found in the behavior of the dielectric. The dielectric absorbs in spite of its great ohmic resistance a certain amount of electric energy during the charging process. During the discharge a part of this energy is given back, the other part has been changed into heat. Therefore we get, when connecting a condenser with a direct current electromotive force, a too great deflection of the galvanometer needle, as we measure not only the electricity which is stored in the sheets of the condenser, but also the electricity absorbed by the dielectric. In the same way we get a too great deflection of the galvanometer needle when discharging the condenser, as the dielectric gives back a certain amount of the absorbed energy. When using alternating currents, the charge and discharge are finished in a very short time, namely, in the half part of a period. The dielectric has not sufficient time to absorb so much energy as when connected with a continuous current electromotive force of the same size. During the discharge it gives back, therefore, also less electric energy. That is the cause why the condensers have a smaller capacity when inserted in an alternating current circuit. The capacity will also be influenced by the number of full periods per second.

Considering the values of the absorbed energy W in the four first experiments, which belong to the same condenser, we find them in good agreement with the law of Mr. Steinmetz. According to this law the losses are proportionate to the squares of the potential differences, and should therefore be equal to 0·352, 0·281, 0·232, 0·186.

I measured in the same way as explained before the capacity of Leyden jars, but in this case it was necessary to connect the Leyden jars in series with a graphite resistance of one megohm. As the electrostatic voltmeter has an impedance of 30 to 40 megohms, the current passing through it could not be neglected if the capacity of the Leyden jars had to be calculated exactly. That makes the calculation more complicated.

Very small Leyden jars, which had a capacity of the same range as the electrostatic voltmeter, were connected in series to the voltmeter. The potential differences e_1 and e_2 of the Leyden jar and the voltmeter have nearly the same phase and are inversely proportional to the capacities of these instruments; therefore the capacity of the Leyden jar can be calculated very easily.

I hope the method that I explained will be suitable to measure the true capacity and the loss of energy of condensers and concentric cables which are inserted in alternating current circuits.

The Chloride Accumulator.

One of the accumulator cells which has figured the most prominently in successful storage battery work is the chloride battery of which mention was made in the issue of ELECTRICITY of August 2, 1893.

The plates are made up of tablets of chlorides of lead and zinc which are held together by a frame of antimonious lead. When first cast, these plates are not capable of use in a storage battery without entirely changing their chemical composition.

This chemical change is brought about by means of a bath of chloride of zinc, or some equivalent substance, in which the plate of tablets is to be immersed in connection with a slab of metallic zinc. This arrangement is a primary battery, in which the zinc acts as the positive element, while the tablets constitute the negative element.

This operation may be performed with current produced by a dynamo, but it is a very tedious and expensive process as compared with reduction by means of zinc.

The electro-chemical action in this combination results in withdrawing the chloride of zinc from the tablets by simple solution in the bath, and the withdrawal of the chlorine of the chloride of lead from the tablets and fixing it in combination with the zinc with the formation of chloride of zinc. It may, therefore, be said that the chloride of lead tablets constitute material which is destined to become active by electrical disintegration, which is brought about when they are connected with the zinc plates in the bath of chloride of zinc.

After the chloride of zinc is withdrawn from the plates there remains a porous mass of metallic lead, in which condition it is ready for use in a storage battery.

The process of manufacture of these plates has been recently described in a paper read before the Franklin Institute by Mr. Herbert Lloyd, General Manager of the company manufacturing these batteries.

The first step in the production of chloride of lead is to melt the pigs of lead in a suitable furnace, and when the lead is brought to a high state of fusion it is conveyed through a pipe into a closed chamber where it is delivered in a fine stream into a jet of dry steam, the result being that the lead is blown into a moderately fine powder and falls on the floor of the chamber. This lead is then dissolved in a bath of acid from which the chloride of lead is afterwards precipitated.

This chloride of lead is then mixed with the proper proportion of chloride of zinc, and the mixture is fused and cast into tablets of any desired shade. The tablets are then placed in a mould where they are spaced a certain distance apart, and a frame of lead is cast about the tablets under pressure, which besides making a very dense frame makes a very perfect contact with the tablets. The latter on account of their shape are securely dovetailed into the frame.

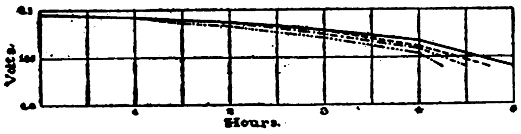
The plate thus formed is then submitted to the reducing process described above.

When the reduction is complete and the plate thoroughly washed in running water, in order to be sure that every trace of chlorine has been removed from the plates, they are all set up as cathodes in a bath of dilute sulphuric acid, plain lead plates being used as permanent anodes in this tank, and a heavy current is passed through them for several hours. If the reduction has been incomplete the chlorine will make itself felt in this operation, and it is practically impossible for a plate to contain any chlorine at this stage.

After removing from the hydrogen bath they are next set up in forming tanks in connection with the plain lead permanent negatives, and here they are charged continuously for several weeks, or until the crystalline, spongy lead has been completely converted into peroxide of lead. The theoretical amount of current necessary to form a pound of peroxide of lead is about 200 ampere hours, and owing to the beautifully porous structure of the plate, this figure holds out very well in practice; the plates will always be found thoroughly peroxidized after they have received a little over the theoretical quantity of current necessary. The positive plates are then set up with the negative plates in a cell, and are charged and discharged a few times until they give their proper capacity.

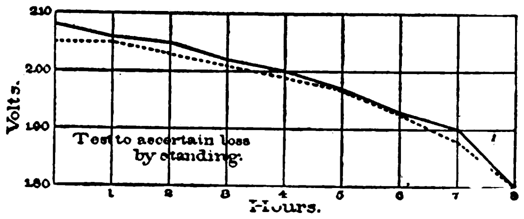
The chloride of zinc is useful, not only to prevent the castings from falling apart on cooling, but it enables any desired density to be produced according to the amount used.

The following curves show the variation in capacity between four cells of the same size, with different percentages of zinc chloride in the castings.

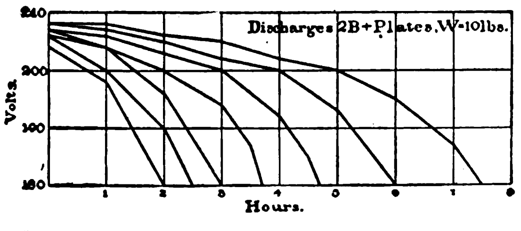


The capacity of cells of this type is from five to six ampere hours per pound of plate. The capacity for weight could be materially increased, but at the loss of durability.

The accompanying set of curves will show the decrease in capacity as the rate is increased. The discharge rate in each of these discharges is above the normal, the lowest discharge being at the rate of three-fourths ampere per pound of plate, and the highest being at the rate of two amperes per pound of plate, or 100 amperes for an ordinary fifty-pound cell, increasing the rate 250 per cent.—decreased capacity but thirty-three per cent.

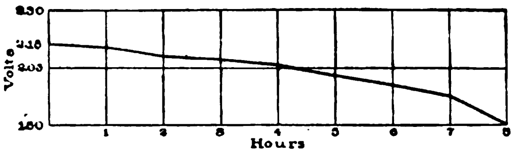


Another set of curves which may be of interest is one showing the effect of allowing a cell to stand charged, the upper curve being for immediate discharge and the lower one after standing charged twenty-four hours. The ampere hours were the same in both cases, but there was a loss in watt hours on standing.



The next curve shows the discharge of a cell at a rate of two-thirds ampere per pound, when it will be seen that over two-thirds of the capacity was obtained above two volts. At the rate of one-half ampere per pound, over three-fourths of the capacity can be obtained above two volts.

Special care has been given to the insulation of the plates. It is well known that the liability of a storage battery to short-circuit has been one of the main causes of trouble. To overcome this, we envelop the positive plate in a piece of beautifully woven asbestos cloth. Between the positive and the negative plate we place a perforated, grooved board of insulating material, the perforations being made opposite the pieces of active material in both plates, leaving free circulation of the electrolyte between the plates, at the same time keeping the asbestos cloth pressed against the face of the positive plate, causing it to form a tight covering over the face of the active material, and while making the plate absolutely safe from short circuit it also adds four-fold to the life of the cell, since the peroxide is held in position instead of being deposited on the bottom of the cell. In traction work this form of insulation is found very beneficial, as the cell is vastly more durable than anything that has been before produced.



Some Measurements of the Temperature Variation in the Electrical Resistance of a Sample of Copper.

BY A. E. KENNELLY AND REGINALD A. FESSENDEN.*

Precision in the determination of the temperature variation of resistance in copper is important not only to electrical science, but also to its applications. Our estimate of the temperature of remote or inaccessible positions, as for example the ocean bed on which a submarine cable lies stretched, or the interior layers of a dynamo armature winding, are often directly dependent for their accuracy upon the completeness of our knowledge of this temperature coefficient.

Electrical text-books in stating the temperature coefficients of copper, usually quote the results of Dr. Matthiessen, or of Dr. Siemens, or both. The results of these two authorities are discordant.

Within the range of chamber temperatures, say from 0° C. to 35° C., the difference between them is practically of little importance. Taking, however, the resistivity of copper at zero as unity, its resistivity at 100° C. is 1.422 by Matthiessen's observations, and 1.388 by those of Siemens, a variation of nearly 2½ per cent., while above 100° C. or below 0° C. this discrepancy increases rapidly.

First in order of date are the elaborate researches of Matthiessen (and of his collaborator Von Bose), appearing in the *Phil. Mag.* for February, 1857, and February, 1861, also in the *Phil. Trans.* for 1858, 1860, 1862 and 1864, the most important series from our present standpoint being those for 1862. The wires tested were varnished with shellac, and immersed in a bath of oil whose temperature was raised by the application of Bunsen burners, and read off by an immersed thermometer. Readings were taken both in ascending and descending series of temperature, and observations are adduced in support of the statements that the application of varnish did not affect the results, and that the observations on a wire heated in a bath of oil were sensibly the same as when the heating took place in air. Matthiessen took six copper wires, all from the same electrolytic source, three annealed and three hard-drawn. Six observations are given of the resistances of each between 0° and 100° C. Having ascertained that all 36 observations accorded very fairly with a parabolic relation between conductivity and temperature, the parabola of closest conformity computed by the method of least squares was $\lambda = 1 - at + bt^2$, or numerically $\lambda = 1 - 0.0038701\ t + 0.000009009\ t^2$, λ being the conductivity at temperature t° C. From this equation, the resistivity (the reciprocal of λ), retaining the terms necessary for accuracy in the fifth digit, at the limit of 100° C. becomes $\rho = 1 + 3.8701\ t \times 10^{-3} + 5.968\ t^2 \times 10^{-6} - 1.177\ t^3 \times 10^{-8} - 9.93\ t^4 \times 10^{-11} - 2.79\ t^5 \times 10^{-13}$. The graph of this equation taking values of ρ as vertical ordinates from a horizontal axis of temperatures as abscissæ, yields a curve bending upwards, so that the temperature variation increases with the temperature, the increase in resistance per degree centigrade being at 0° C. 0.387 per cent., and at 100° C. 0.50 per cent. of the resistivity at zero C. Matthiessen points out that this bending upwards of the curve is distinctly indicated by his results, and that no straight line can represent them. Not only the 36 observations on copper wires, but more than 200 quoted observations on other metals, all point to a temperature coefficient augmenting with temperature and negative the supposition of a simple linear relationship between the variables.

---

* Read at the International Electrical Congress, Chicago.

Dr. Siemens' researches formed the subject of his Bakerian lecture in 1871. They were undertaken with the object of obtaining a practically reliable scale for the electropyrometer which bears his name, rather than for the direct purposes of scientific research. After pointing out that Matthiessen's formula can on its own evidence be only fairly applicable between the limits of 0° and 100° C., Dr. Siemens proceeds to advance some interesting although arbitrary hypotheses for the law of temperature variation in metallic resistances, and then shows that his experimental observations on copper and four other metals are capable of close representation by the empirical formula so obtained. These observations were made on wires heated in air, and also in oil, up to 350° C. with mercury thermometers, and in one series up to 850° C. with a platinum ball pyrometer, an instrument whose indications assumed a constant specific heat in the platinum ball throughout the range of temperature employed.

Dr. Siemens' formula for copper is $\rho = 0.026577 \sqrt{T} + 0.0031443\ T - 0.29751$, where ρ is the ratio of the resistivity at any absolute temperature, T, to that at zero centigrade, or T = 273°. For 100° C., or T = 383°, $\rho = 1.3885$, and the rate of increase of resistivity is at 0° C. 0.394 per cent., and at 100° C. 0.383 per cent. of the resistivity at zero C. The graph of the equation is a curve bending slowly downwards towards the axis of temperatures, and the temperature variation diminishes as the temperature rises. All the 170 observations recorded in the paper indicate that the curve bends downward, while all the 250 observations in Matthiessen's 1862 paper make the curve bend upwards. The discrepancy between these two series of results becomes very noticeable between 70° and 100° C.

Professors Dewar and Fleming have published in the *Phil. Mag.* for October, 1892, a number of observations in the resistivity of metals and alloys at temperatures between $-200°$ C. and $+100°$ C., one series for copper being included. The resistivity of the copper wire is stated to have been 1358 C. G. S. U. at 0.7° C., equivalent to 1349 at 0° C., and since Matthiessen's standard is 1594 at zero C., this represents a conductivity 18 per cent. higher than Matthiessen's standard. Aside, however, from this remarkable and perhaps debatable statement, the graph of the observed values of resistance with respect to temperature is very nearly a straight line throughout the whole range, the resistivity at 100° C. being 1.424 times greater than that at 0° C, and the temperature coefficient being approximately 0.424 per cent. per degree centigrade for all temperatures between $-200°$ and $+100°$ C.

Messrs. Cailletet and Bouty, in the *Comptes Rendus* for 1885, give an observed temperature coefficient for copper of 0.418 per cent. per degree C., expressed by $\rho_t = \rho_o (1 + 0.00418\ t)$ between zero and $-58°$ C., and 0.425 per cent. from $-69°$ to 123° C., $\rho_t = \rho_o (1 + 0.00425\ t)$.

In Poggendorf's *Annalen* for June, 1858, Herr Arndtsen quotes a uniform temperature coefficient of 0.369 per cent. per degree from zero to 200° C. He gives, however, one series of observed resistance with a copper wire (containing 0.15 of iron) between 0° and 100° C., showing a linear relation, or a temperature coefficient of 0.394 per cent. per degree C., $= \rho_o (1 + 0.00394\ t)$, and he points out that the divergences from the straight line are within the limits of the observation error.

In view of the discrepancies existing between these best known measurements of the temperature coefficient of copper, Arndtsen, Cailletet and Bouty giving results practically represented by straight lines, Siemens' results with the line bending distinctly downward and Matthiessen's results with the line bending as distinctly upward, the writers of this paper made a number of measurements in the spring of 1890 upon a sample of copper wire. These measurements were made with great care, and repeated until similar results were obtained in successive series. The wire tested was sealed within the bulb of an air thermometer, so that there could be no appreciable variation between the temperature of the wire itself and the temperature indicated by the pressure of the air in the bulb it occupied. The final results, after full corrections for expansion of the bulb, etc., indicate a linear relation between the resistance and temperature of the wire between the limits of 20° C. and 250° C., represented by the equation $\rho_t = \rho_o (1 + 0.00406\ t)$, indicating a uniform temperature coefficient of 0.406 per cent. per degree C. throughout the range, the maximum observed being 0.4097 per cent., and the minimum 0.399 per cent at any point. The details of these measurements are here submitted in the form of an appendix, not only in support of the statements made concerning them, but also because the experimental arrangements of apparatus finally successful were the outcome of a series of experimental failures, and it is believed that the details of construction may be of service to those who desire to adopt the same method of measurement.

Concerning the conclusions that may be drawn, we feel only justified in saying that copper can be found in which a linear relationship holds between resistance and temperature between 20° C. and 250° C., and within the range of small observation errors. It is of course possible that in different samples of wire the temperature coefficient may increase or diminish with the temperature. In other words, the second differential coefficient of resistance with respect to temperature may perhaps in some samples be either positive or negative, but it seems desirable that fresh measurements should be made, and evidence collected to settle this point, and we submit the view that the best experimental means of measuring the temperature, and to ensure the coincidence between the measured temperature and that of the tested wire, is to enclose the latter in the bulb of an air thermometer in the manner here described.

NOTE ON THE TEMPERATURE OF LOWEST VISIBLE RED HEAT.

A few measurements were made of the resistance of copper wires enclosed in exhausted glass tubes and gradually raised to just visible red hea by gradually increasing the current strength through them. The tubes were 30 cms. long, and 2 cms. external and 1.8 cms. internal diameter. The platinum wires were sealed into the glass at each end and connected with the copper wire, one to carry the heating current and the other to act as "pressure wire" in order to eliminate the resistance of the first, or platinum electrode. The copper wire stretched along the axis of the exhausted tube was 30.4 cms. long and 0.0015″ (0.0038 cm.) in diameter. Measuring the resistance of these wires at normal temperature with a very feeble current, they were then raised to redness and their resistance observed under that condition in a darkened room.

Reckoning back with the linear temperature coefficient of 0.00406 from the normal temperature to zero centigrade, the resistance of the wire was found to be three times that at zero when visible luminosity was just attained, the mean calculated ratio being in fact 3.001. If the same linear temperature coefficient be assumed throughout that whole range, the corresponding temperature of lowest visible luminosity becomes 493° C. in this instance.

The method is very sensitive in application, and repeated trials with the same wire and same observer would usually fall within two degrees centigrade by resistance valuation. There was, however, a systematic variation between the observations when the observers were exchanged, amounting to about three degrees of centigrade, and since the criterion of appreciable visibility is merely physiological, it is perhaps impossible to accurately define it. From the sensations experienced in observing, it might be supposed that habit or physical condition might appreciably influence the range of visual appreciation, after the manner of a personal equation.

In conclusion, we desire to express our acknowledgments to Mr. Thomas A. Edison, in whose laboratory the above research was conducted.

(To be continued.)

An ingenious instrument for automatically indicating the place of a fault on underground conductors is being used in Berlin. An alarm is sounded at the central station the moment a fault is developed, and the location is indicated at the same moment. The usual pressure wires are used, and are so connected that a certain difference of potential exists between the copper conductor and the pressure wire. When a cable is damaged the short circuit which then occurs between the pressure wire and the copper conductor produces a change in the voltage existing between them, which in turn actuates a relay and an alarm at the station. The relay also controls an annunciator, which denotes the position of the fault by the dropping of a square devoted to the district affected. The further efficiency of the underground electric service in Berlin is maintained by ground detectors at the station, which show the condition of the insulation, not only of the whole network, but of every single district.

A multiple filament lamp, which has been used for some time in Germany, is thus described: It contains a number of filaments united in common at the upper part; each half can, therefore, be used with any of the others, thus enabling all but one-half of a filament to be used up or broken before the lamp must be renewed; the extra expense is much less than the equivalent in the new lamps; furthermore, several filaments can be used at once, thus increasing the candle power (unless filaments be used which do not blacken the globe, there would probably be little economy, as the lamp bulb would become too black long before all the filaments are consumed).

Standard of Illumination. A prominent topic which failed to be definitely acted upon by the Chamber of Delegates of the International Electrical Congress is the standard for units of light and illumination. This subject is a most important one and the total absence of any satisfactory standard at present gives rise to constant misunderstandings.

Professor Houston in his inaugural address to the American Institute of Electrical Engineers gave a review of the work of the Congress, and suggested the propriety of taking up this unfinished work by the Institute, making it distinctively the work of that body. The proposition was at once adopted, and a committee was appointed to carry out the plans suggested. Mr. Preece as an honorary member has also offered to co-operate with this work in England.

This kind of an undertaking seems to be specially suitable to the Institute, not only because it is the representative electrical society of this country, but because it includes among its members almost all of the electricians and electrical engineers connected with our colleges, universities, etc., than whom none are better qualified both by ability and opportunity for pursuing these investigations.

Prof. Houston's plan was to increase the regular committee of the Institute on Units and Standards, and to appoint a number of sub-committees to carry on the necessary experimental work, a chairman for each sub-committee being named in such colleges as possess the necessary laboratory equipments for this line of experimental work.

Should the Institute proceed in this matter it will not only supply a much needed unit, but will add to the high standing as a scientific body which it has already attained.

……o……

The Storage Battery Situation. One of our contemporaries, in discussing briefly the recent decision of Judge Colt against the Milford and Hopedale Railroad Company for infringement of the Brush storage battery patent took a distorted view of the storage battery situation, as it does of every other subject whenever the corns of the General Electric Company are in danger of being trod upon: "With their contention now firmly established and the Faure patent on the use of active material in the form of paste, paint or cement expired, it only requires a liberal policy on the part of the victors to give a great impetus to the storage battery industry. The present licensees under the Brush patents have always professed a considerate policy for those whom the courts have declared infringers of their patents."

In the first place, the production of a successful storage battery, either for accumulator service or for traction work, does not depend upon the Brush patent. The problem has been solved entirely independent of that patent; and moreover, the Consolidated Electric Storage Company, which controls the Brush patent, has *never* produced a practical commercial product. Experimenters in this field will use good judgment in working out their own ideas rather than depending upon the liberality of "the victors."

As to the "considerate policy" which the Brush licensees have professed, the correspondence between Mr. Bracken, of the Consolidated Company, and Mr. Gibbs, of the Electric Storage Battery Company of Philadelphia, published in ELECTRICITY for August 2, shows clearly the hypocrisy of any such claims.

And moreover, it is a fact beyond dispute that not only has the Consolidated Company so far failed to make a good battery, but every one of the companies which have been declared infringers by the courts have also failed. The system of the Milford and Hopedale people possesses special merits, but they do not rest in the battery part of the outfit.

Elsewhere in this issue will be found an article dealing with the Choride Accumulator. We invite the attention of our contemporary, and also of the Consolidated Electric Storage Company, to the facts presented.

Right here in our own city Messrs. Waddell-Entz have been conducting for some months an experiment in storage battery traction which is also worthy of note. It seems now to have fairly passed the experimental stage. They are running six cars successfully, which have traversed already 40,000 square miles without any mishaps of any nature. They have at no time delayed traffic, or been hauled by horses. They go. If we remember correctly, this battery has not been claimed to be an infringement of the Brush patents.

Thus we see that the storage battery problem is marching along to a solution entirely independent of the Brush patent, and without regard to the bullying tactics of the owners of that patent.

……o……

Where Accumulators are Practical. In spite of the slow introduction of accumulators in this country there are a great many uses to which they might be profitably put that have been pointed out to us by the practice in France and Germany, where they are in extensive use. They are considered indispensable in many of the largest central stations in those countries, although here no attempt has been made to introduce them for this work.

It is pretty well settled that an efficient battery whose depreciation is not too rapid adds considerably to the economy of a central station by evening the output of the steam plant through the day.

In every station the load line is very variable; during the greater part of the day it runs fairly even at a small amount and towards night increases abruptly to a maximum which lasts only two or three hours, and then falls off to almost nothing later in the night. This is true of almost every incandescent lighting station, and accumulators are admirably adapted to carry the load at the times when the engines are running almost empty. By charging the batteries during the day the load on the engines is increased to an amount at which they run with a higher efficiency, and the stored current may be used to carry the night load and the plant shut down. It may also be used to supplement the dynamos during the hours of heaviest load, and in this way the maximum output of a station may be made considerably greater than the capacity of its steam plant.

The use of accumulator sub-stations has been found advantageous in a number of places, and they are often used in the capacity of transformers to utilize a high tension current by which they are charged during the daytime for an incandescent lighting circuit in the evening. This plan is adopted in the Papp stations in Paris, where twenty-four stations are all charged in series, each station having two sets of batteries, one of which is discharged while the other is being charged.

In railway work there have been a few experiments with battery cars in this country, but the great number of unreliable batteries on the market, and the uncertain legal status of many of them, have been sufficient to check any great progress in this direction. That storage batteries are entirely feasible for street railway work is shown by their success in Paris, where one company operating about forty cars has found them entirely satisfactory after a test of two years' service.

Accumulators have also been found of service on trolley roads for some purposes. In Dover, N.H., the attempt was made to feed the trolley line on a steep grade some distance from the power house with batteries in order to run this section at a higher voltage than the rest of the line, and the plan appears to be entirely feasible. Charging batteries during the time of light load on street railway circuits for the distribution of power has also been favorably considered and there are besides a great number of applications for which the storage battery is specially adapted. These applications are now no longer a matter of experiment, as the value of the storage battery has been thoroughly established abroad, and the absence of any progress here in this direction is invariably remarked by our foreign visitors.

......o......

An operetta is to be produced in Brooklyn this week entitled "The Lieutenant's Dilemma." The author doubtless drew for his plot upon the incidents connected with the dilemma in which Lieutenant S. D. Greene found himself when he was confronted with the alternative of forfeiting Mr. Coffin's good opinion or of committing perjury in the matter of the libel suit against Electricity. Mr. Greene finally elected to commit perjury rather than to offend Mr. Coffin.

......o......

The rule which has heretofore been in force against the admission of cuts in advertisements on the first page of Electricity has been modified. Hereafter we will accept cuts not to exceed one inch square. We are disposed to make all reasonable concessions to our friends.

......o......

Mr. O. T. Crosby, who is to be in Milwaukee this week, will make the circuit of the various district offices on his return trip to New York. Heretofore Mr. Crosby's calls on the district managers have not been productive of good. At Cincinnati, in particular, such calls have usually been followed by a sale of apparatus by the Westinghouse Company. Mr. Crosby should hie himself to the laboratory, where he naturally belongs.

No Further Reasons Necessary. Last year, when the General Electric balloon was soaring skyward, officials of the company and its boomers in Wall Street were stoutly claiming that the company was doing business at the rate of about $30,000,000, on which it was earning 17 per cent. net. It was stated, we believe, that the earnings of the first year would be more than enough to meet fixed charges and dividends for two years. Owing partly to the glamour of mystery which has surrounded all matters electrical in the public mind, and partly to the high standing of several of the directors of the company, these reports found many believers. No doubt some of the directors themselves believed them. They *must* have had absolute faith in the property or they would not, as some of them did, recommend friends and relatives to invest their savings and even funds held in trust. Electricity, however, did not believe them. And to estimate Electricity's position correctly, it must always be borne in mind that we started our campaign against the corrupt business methods and extravagant claims of the stock boomers *over a year* ago. On August 31, 1892, we began, knowing then, as all the world knows now, that the booming of General Electric shares was little better than a swindle; that the scheme must collapse, and that widespread injury to the financial interests of the entire trade must result. In the issue for September 7, 1892, we had the following:

> Even if there were no other electrical concerns in the field, the scheme would only be a partial success. Light and power are now recognized as necessities in all civilized communities. They are in the nature of luxuries, perhaps, but they are something which the people insist upon having, and for which they are willing to pay a good price. But there is a point beyond which they would rebel, and all electrical development on these lines would be at a standstill.
>
> There is no necessity, however, for anxiety on this point. There are scores of electrical manufacturing and supply houses outside of the Trust, fully equipped, and capable of taking care of all the new business and of supplying additional equipment for existing plants at prices ensuring an honest profit only.
>
> We hope, for the good name of the Electrical Industry of America, that English capitalists will not invest their money in this scheme in the belief that it is a promising enterprise and likely to pay large dividends. The whole range of American electric investments would be under a stigma which it would take years to overcome, and a handful of speculators would reap the profits.

And this has been the keynote of the campaign, in which Electricity has *not* been the loser.

Early in this year the stock began to go off. It had reached a ridiculously low figure for an 8 per cent. stock even before the present general depression. Column upon column of supposed explanations have been published to account for it, none of which have been correct. Officers of the company have backed up old lies with new lies for very fresh occasion, until the record is a sickening one.

The critics of the daily press seem unable to believe that the actual condition of the company, its assets and its business, have NEVER been such as to warrant a higher quotation than 50 for the shares. They were so thoroughly humbugged last fall that they still cling to the fallacy that at that time the stock was valuable, and they are continually seeking for reasons for the great drop. They seek, but they do not find. They are all looking in the wrong direction, or passing over the simple truth in the hope of finding a sensational and hidden mystery.

The following table, which has been compiled with great care, will save these critics and financiers generally a deal of trouble. Although the exact figures are at our disposal, we present the table in round numbers for ready comprehension, and the statements may be relied on :

COMPARATIVE TABLE SHOWING BUSINESS DONE BY THE EDISON GENERAL COMPANY, 1891-92, AND GENERAL ELECTRIC COMPANY, 1892-93.

EDISON GENERAL ELECTRIC.		GENERAL ELECTRIC.	
Eastern District	$4,000,000	New York Office	$3,000,000
		Washington Office	200,000
		Syracuse Office	150,000
		Penna. G. E. (Phila. and Pittsburg)	1,000,000
Central District	3,500,000	Chicago Office	3,750,000
		Cincinnati Office	1,750,000
		Portion of N. W. General Elec. territory	500,000
New England District	600,000	Boston Office	1,500,000
Southern District	350,000	Atlanta Office	350,000
Rocky Mountain District	500,000	Denver Office	400,000
Pacific Coast District	250,000	San Francisco Office	250,000
Pacific Northwest District	450,000	Portion of the N. W. General Electric Company's territory not included in above	500,000
Canadian District	350,000	Canadian	300,000
Total business done	$10,000,000	Total business done	$13,650,000

Previous to the consolidation the Thomson-Houston Company had done just about the same volume of business as the Edison General.

So we see that the attempt to form a Trust, to monopolize the electrical business, was abortive, and that the General Electric Company has done only 20 per cent. more business than each of the chief underlying companies did as separate organizations.

In addition to the above there has been some business turned in by the Thomson-Houston International Company, the figures for which are not at hand, but upon which there has been no profit.

Electrical manufacturing companies, with economical management, can earn 15 per cent. net on business done. They cannot earn more, and the average would be about 12 per cent. The General Electric Company has not been economically managed; and even if it had been, the business done, at the maximum percentage of profit, would not have been sufficient to pay dividends on its enormous capitalization. Its selling expenses have been about 75 per cent. of the selling expenses of the two underlying companies previous to the consolidation.

Further than this, it is susceptible of proof that *all* the business done by the Chicago, Cincinnati and some other offices was done at an absolute loss.

The General Electric Company has failed from simple lack of business, as men die from lack of breath.

A STARTLING RUMOR.

CLEVELAND, O., Oct. 13.—Among the many sensational rumors afloat here as to the Brush Company and its future prospects is one that a matter of upwards of half a million of dollars which ought to be in the Brush treasury has been loaned to the Fort Wayne and General Electric companies on notes which are past due and have not been paid. R.

Legal Notes.

On the petition of certain creditors of the Oshkosh (Wis.) Electric Light and Power Company, C. C. Paige has been appointed receiver of that concern. Mr. Paige, who is also superintendent, says that this proceeding is the result of a falling out among the stockholders of the company, many of whom are creditors. He maintains that the company will fulfil all contracts and pay its debts.

The Electrical Forging Company, a corporation of Boston, Mass., having an exhibit in the Electricity Building on the World's Fair grounds, confessed judgment at Chicago, on the 6th inst., for sums aggregating nearly $68,000.

An action has been begun in the United States Circuit Court by Charles W. Russell and John I. Drake, of Providence, to restrain the Utica Electric Supply and Manufacturing Company from the manufacture or sale of a device for suspending arc lights over streets. The defendant is cited to appear at the term of court which opens in Utica, N. Y., on the first Monday in November. The defendant claims a specific agreement with the inventors to manufacture the device.

The *N. Y. Merchants' Review* says: "Electricity is used to great advantage by enterprising retail storekeepers in the larger cities, not only for illuminating purposes but for window displays. The dry goods stores especially often produce very beautiful effects with electric lights in their windows, a recent instance being on the occasion of the opening of a new store in Brooklyn. Excellent imitations of revolving pinwheels were shown in one of the windows, the color of the wheels being made to change from time to time to correspond with the changing hues of the genuine articles at exhibitions of fireworks. Brilliant stars corruscated and twinkled in the same window, while in another a fac-simile of a peacock attracted much attention. The eyes and crest of the bird were made brilliant with electric lights, and the spreading tail was studded with tiny electric bulbs, the whole production a very beautiful and life-like effect. The expense of the display must have been considerable, but as immense crowds were drawn to the store the proprietors no doubt were well paid for their outlay."

A New Method for the Control of Electric Energy.—II.

BY D. MCFARLAN MOORE.*

The two greatest desiderata in connection with the advancement of electrical science, and those which, because they have not been satisfied and fulfilled, have, in a measure, for a number of years barred further progress in the most rapidly advanced industry in the history of the world, are, first, the use of the efficient low voltage lamp on the efficient high voltage current, and second, the prolonging of the life of these lamps. The manufacture of high voltage incandescent lamps is a subject much agitated at present, owing to the fact that the benefit to be derived from a high voltage is almost incalculable, as the capacity of the mains now used by central stations might easily be trebled. But not only does the successful solution of this problem seem impossible in this direction, but it is now unnecessary. The greatest advantage of the alternating system over the direct current system is that, by means of converters, lamps of low resistance, and therefore high efficiency, can be used. It appears, then, that the main advantage (without some disadvantages) of alternating systems can be transferred to the continuous system by using in each socket, or on every circuit, varying pressure contacts, causing an interrupted current of any desired voltage, thus increasing the possibilities of this system to an enormous extent owing to the immense saving in copper conductors.

If an appurtenance of this construction is operated by a centrifugal governor attached to a motor, the best results as regards economy and regulation can be obtained as the voltage will then vary directly as the torque, and the electric energy required will be proportional to the power developed. Owing to the minimum size of this device it can be made an integral part of the motor. The salient disadvantages of a resistance box that can now be overcome by constructing apparatus as described, are: first, size; second, weight; third, susceptibility to changes in temperature, that is, variation in resistance; fourth, poor contact caused by the burning of clips and loosening of wires; fifth, heating and the great fire risk consequent thereto. The new method is certainly unique, and its application will be the means of affording great convenience under many circumstances.

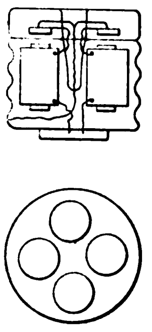

FIG. 6.

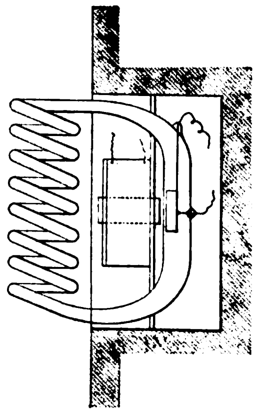

FIG. 7.

Owing to its constancy, due to its non-susceptibility to temperature changes, it can be adopted, when the adjustment screw is used in connection with a graduated dial, with great facility as an electric gauge.

Experiment shows that the continuous sparking (though slight) of the contacts in a vacuum sets in motion the ether molecules, causing a beautiful soft blue phosphorescent light similar to that produced by Geissler tubes. While Maxwell was the first to note that a disruptive discharge was oscillatory and set up vibrations in the ether, Professor Henry demonstrated it experimentally. The conductive discharge which occurs when vibrating metallic electrodes are used, and therefore of small resistance, probably consists of partial discharges producing oscillations which in turn are due to the induction of the current upon itself in the magnet. But the quantity of current passing bears a relation to the amount of disturbance, and the greater the impedance the less the current; also, the more rapid the vibrations or frequency of interruptions, the more prominent becomes the self-induction and the less the true ohmic resistance in the control of the current. These oscillations are increased if the arc is in a strong magnetic field, as it raises the E. M. F. but deteriorates the electrodes more rapidly. If this magnetic field be variable, the effect is magnified, and since free atoms or molecules are made to collide with one another, varying the surrounding potential, we can in a measure account for this phenomenon in that theoretically following every impact the electrostatic force falls from its maximum quantity to zero.

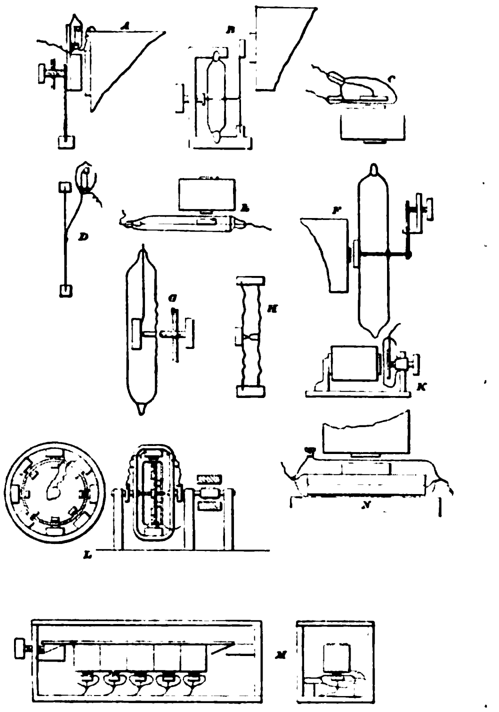

FIG. 8.

Now, by increasing this effect, a light may be produced of greater efficiency than is now obtained by the incandescent filament, which is very inefficient. This method of lighting is a radical departure from anything heretofore proposed, as it will be producing phosphorescent light due to ether oscillations without the use of an alternating current (although there is no reason for not using it) at high tension with expensive and impracticable condensers and transformers. The value of this system will be more clearly discerned when it is remembered that the elements above mentioned as being done away with are those which stand in the way of phosphorescent lighting becoming commercial at present.

Merely the use of this simple and inexpensive device with the direct or alternating low tension current produces phosphorescent light. There is no objection, however, to using high voltages; the effect is simply increased, because the greater the stress between the terminals and the more intense the magnetic field the more rapid will be the interruptions of the current. And the greater the number of impacts per unit of time, the more intense the heating effect and the more economical the light will be. The most economical potential (there must be such) for given electrodes can only be found by trial, because the greater the heat the less the permanency of the vacuum. The phosphorescence is probably in a measure at least caused by the atomic disturbance due to the actual mechanical movement of the armature in the vacuum, the impacts and the static electricity that may be caused thereby in conjunction with the rapid disruptive discharges. This disturbance or action of varying electrostatic force consists in the rapidly moving or vibrating of charged atoms or molecules coming violently in contact with one another, producing friction, heat, light. In fact, the generation of light due to friction within or without a bulb containing rectified gas, and caused by inductive action, is a subject of much interest. Experiment seems to indicate (see plates 8 and 9, L, R, S, T, W, X) that the amount of phosphorescence depends more on the number of contacts in different parts of the vacuum per unit of time than on the influence of a surrounding magnetic field.

---

* Read at the seventy-ninth meeting of the American Institute of Electrical Engineers, New York, September 20, 1893.

By reason of the enclosed space in which miniature incandescent arcs can be made to occur in rapid succession throughout its extent, the heat resulting therefrom is conserved and aids in accomplishing the result sought for, a luminosity of maximum radiation emanating from a source of considerable area.

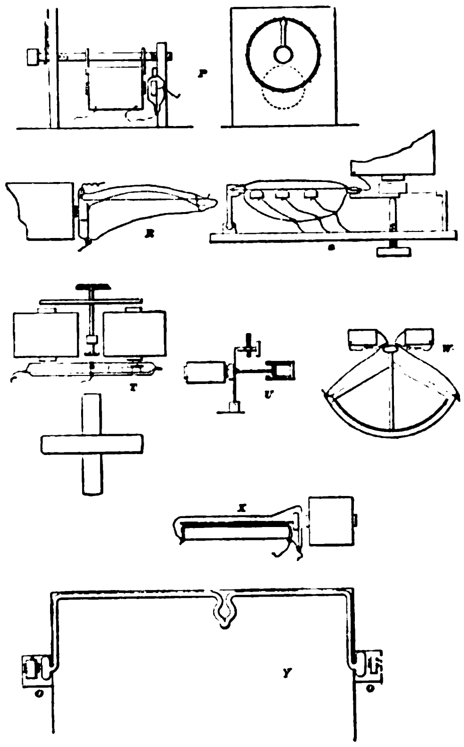

Fig. 9.

If any inert gas, such as oxygen or nitrogen, be substituted for the vacuum, the phosphorescent effect will most likely be intensified on account of more vigorous molecular action, but the life of the electrodes may be shortened. It might be advisable with metallic electrodes to use carburetted hydrogen because when decomposed it would not affect the metal. Owing to the actual contact of the electrodes, their volatilization or disintegration due to the arc is reduced to a minimum, that is, much less than is the case when high tension discharges occur. Of course, the degree of disintegration and the amount of deposit in the bulb depend largely on the nature of the electrodes, aluminium probably being the best. However, the more perfect the vacuum, the less the deoxidization and volatilization, because combustion requires oxygen.

Fig. 6 shows one form of phosphorescent lamp complete, its size a little larger than the base of an ordinary lamp, the C. P. being developed by multiple contacts.

A matter of great importance in the design of a lamp of this description is the form and nature of the evacuated space, partially determined by the melting point of the glass, also whether it is advisable to use double or even triple bulbs, one within the other.

Fig. 7 denotes one of the many forms of lamps that suggest themselves, but experience only can prove that which is most efficient.

The study of this branch of physics and of these highly interesting phenomena brings to our minds innumerable ideas in connection with them which cannot be treated individually in a short paper. A few only of these are illustrated in plates 8 and 9.

If will be noted that the point in Fig. A is that the bulb does not contain the armature, but is mounted upon it, and therefore can be made very small. As shown, its operation its due to the principle of momentum. This is not the best form for producing phosphorescence, in that the heat in the armature caused by dynamic action is not dissipated in producing molecular disturbance in the bulb. Fig. B, elasticity of the glass bulb is suggested. Fig. E, rapid vibrations and quick break. For rapid action use short, thick magnet. Fig. L, friction within bulb and electro-magnetic rotation. Figs. M and N, resistance boxes where gravity is utilized in place of springs.

In Fig. N carbon plates are used for the electrodes, and the bulb should be made of the first quality of refractory glass. On account of the expansion of the gases, formed by excessive sparking, a valve is shown to permit of their escape before a disruption of the glass could occur. This pressure, together with the absence of combustion, bears an important relation to the disintegration of the carbon.

P is a graduated dial attachment to indicate character of current passing; U, vacuum piston instead of spring; W, movement of metal screens upon each other, pendulum action, producing maximum sparking; T, screen with revolving brushes, resulting in a brilliant phosphorescent lighting effect; V suggests transmission of light by phosphorescent tubes generated in concealed portions, O O.

Owing to the immense production of incandescent lamps, the manufacture of evacuated bulbs has been so perfected and cheapened that general current control with this system will probably be many per cent. cheaper than any method now in use.

There are a large variety of rheostats and current controllers on the market designed to be used medically, and since the interrupted current, owing to its peculiar effects on the human system, is now being used in medicine, no better form of current controller could be devised than by employing the principle under consideration, as more delicate currents can be supplied than by any other method or means, owing to the steady rate of vibration caused by the non-deoxidization of the contacts in the vacuum. This is clearly proven in that the pitch of the note produced by the vibrating armature is almost constant.

A varying-in-pressure contact could be used with advantage in connection with all delicate measuring instruments. It would materially aid in making them "dead beat," as it could then be made impossible to strain them by suddenly turning on and off the current.

It is hoped that this paper has been of interest to the Institute, and that it will give new impulse to investigations leading to the discovery of a more economical method for transforming mechanical motion into light, and an ideal means for controlling electric currents.

(Concluded.)

The Electric Manufacturing Company of Rockford, Ill., which had been idle since last spring, has started again on full time with a full complement of men.

The Proposed Electric Conduit Railway in Washington.

President Stevenson of the Metropolitan Railroad Company, Washington, D. C., has made a proposition to the District Committee to install the Buda-Pesth system of conduit on the Ninth street line. He appeared before the committee on the 11th inst., in company with Mr. Wright, of the firm of Misenburg & Wright, who made a statement to the committee giving concise details of the working of the proposed system in the city of Buda-Pesth, Austria-Hungary, where it has been in successful operation for three years. The first line was opened in July, 1889, and gave such satisfaction that the company at once began extending its system, and there are now twenty-five miles of the road in the city. The company have secured a franchise to operate the system in Vienna and are asking for a franchise in Berlin. In 1892 the road carried nearly 11,000,000 passengers in Buda-Pesth.

In reply to questions put by several members of the committee, Mr. Wright explained the points of superiority of the conduit electric system over the cable system, among which were its greater economy and adaptability to the volume of traffic. As compared with other electric systems using conduits, Mr. Wright presented the fact that the Buda-Pesth system was the only one that has carried passengers year in and year out successfully. There was no danger to the public in its operation, for the electricity is conducted on an angle-iron the shape of which is such that the trolley cannot get away from the contact, and even in the case of children playing on the road and punching down in the slot, they would have to establish connection between both angle-irons, a thing almost impossible.

Mr. Stephenson added that the Metropolitan Railroad Company had placed the matter before its board of directors, and is now ready to accept the offer of Mr. Wright to install the system on its lines, if Congress gives its consent. He is satisfied that the system can be successfully operated, and is contented with the guarantee of Mr. Wright.

The committee adjourned without taking action, but apparently favorably impressed by the statements set forth.

A German Colliery Electric Locomotive.

The first electric locomotive put down at the German collieries at Kray, known as the United Bonifacius, has recently been replaced by a new one of improved design, constructed by the well-known firm of Messrs. Schuckert & Company, of Nuremberg. The new locomotive, which is described in *Industries and Iron*, differs from its predecessor in that the battery of accumulators is not carried on the motor as in the old form, but on a separate truck, which forms a kind of tender. By this arrangement it is claimed that the locomotive is much more easily handled, and that the whole apparatus is greatly simplified. The direction of running can be changed at will without the necessity of removing the brushes of the motor. The latter is series wound, and the magnet-winding is divided into sections so that the speed of the locomotive may be easily regulated by means of a regulator-switch. Seats for the driver are provided at each end of the locomotive in close proximity to which are placed switching arrangements. The locomotive has been so designed with regard to its dimensions as to admit of being taken down the shaft in the cage, and also to allow of its having free access to the galleries and cuttings. Ample brake-power and lubricating arrangements have been provided and at full speed the locomotive can attain a speed of 110 metres per minute.

The battery of accumulators carried on the tender was supplied by the Hagen Accumulatorfabrik and comprises forty cells. The latter are inclosed in suitable, strong cases the top of which consists of a glass plate having a small hole in the centre. Special precautions are taken to prevent any spilling of the acid in the accumulators while the locomotive is in operation. The connection between the battery and the switching apparatus on the locomotive is by means of a flexible conductor and a clip contact. The capacity of the accumulators is sufficient for the working of the locomotive with a normal load of ten loaded wagons during one shift. The locomotive is also arranged to work by means of an overhead conductor, the rails in this case serving as the return.

Personals.

Mr. Frank A. Myer, the genial representative of the E. S. Greeley Company, New York, spent a little time among his old acquaintances in Boston this week, and honored our office with a call. Frank A. has made up his mind never to like Boston. He never tires of letting his friends know that Gotham is good enough for him.

City Electrician Henry A. Chase has been promoted by city council to be director of the Signal Service for Boston.

Mr. J. E. Talbot, so well known by the electrical fraternity throughout the East, has been spending a few days on his old stamping-ground. Everybody was pleased to see J. E. T.

Boston Notes.

The most ominous sign of the times in Boston electrical and financial circles is the almost deathlike silence that has come over the General Electric Company's affairs during the last week or two. As far as news goes, the Trust is dead for the present, and both the outside public and the great army of small stockholders are querying what will be the next move. The roseate paragraphs that were wont to appear every day or two in the various papers—morning, evening and financial—apparently failed of their purpose to restore the confidence of the public, so the chief of the Trust's information and press bureau is now devoting himself to other and, it is hoped, more successful and profitable work. It is the unanimous opinion of every one that to play off those paragraphs on a public that has paid so dearly for its electrical whistle was adding only insult to injury. The investors had lost their money and were in no humor for being fooled. That the executive chiefs of the Trust have realized this, is proven by the discontinuance of all news items from the press and advertising department of the company. Meantime many of the old employees, tired of the prolonged vacation, are seeking new appointments and finding them very hard to meet with. They are among those who believe least in the misstatements that have from time to time been published, and take no stock in the oft-repeated promises that the works will start up full blast in a few weeks. About the latest announcement, now more than a week old, was that there was the most perfect harmony prevailing in the Board of Directors, and further that Mr. Coffin has no idea of resigning—at present.

That perennial dispute over the prospective laying of electric car tracks along Brattle street, Cambridge, has again cropped up as vigorously as ever. The matter has been argued this week before the Railroad Commissioners, quite a number of prominent citizens speaking against the project. After two days' hearing, pro and con, the commissioners now have the matter under advisement.

A somewhat unusual funeral procession passed through the streets of Boston a few days ago. The remains of a motorman, who had been in the employ of the West End Railway Company for some years and was very popular with his fellow-workmen, were to be interred in Calvary Cemetery, and in the funeral cortege was the car deceased had run for three years, heavily draped in black. The car moved at the head of the procession.

The Cambridge City Council may be considered to occupy premier place in the matter of having disputes over electrical concerns. As we have noted above, the electric railway is being opposed there for certain reasons, and now the New England Telephone and Telegraph Company has determined upon a line of action that may involve the Cambridge city fathers in a lively kind of a fight. In June last the City Council very precipitately passed a restrictive ordinance which was a severe blow to the Telephone Company. This ordinance, introduced, discussed and adopted all in a single evening, gave the city the privilege to revoke any and all pole locations if the conditions imposed in any one location were not observed. The Telephone Company kicked hard against it, but without avail. Now it has got round to its innings, and to get even with the city fathers it has cancelled all the reduced and free telephone service to the city and notified the Council that in future Cambridge must pay just the same as private subscribers. This fact was embodied in the following letter that has just been forwarded :

To the Honorable the Mayor and City Council of the City of Cambridge.—Gentlemen : We have this day sent to the treasurer of your city notice cancelling all reduced and free rates for telephone service to the city, to take effect one month from this date. Thereafter the rates for telephone exchange service furnished the city will be the regular standard rates to subscribers for similar service.

We regret our inability to continue our gratuities in the way of service, but the onerous conditions imposed by your city upon the conduct of our business and the restrictions placed upon the extension of our facilities to meet the growing demands of the public make it necessary for us to curtail privileges heretofore extended.

Respectfully,
JASPER N. KELLAR.
General Manager New England Telephone and Telegraph Company.

Cambridge as a city has another stubborn fight on its hands for the coming winter, sure.

The hearing of the suit, Mather Electric Company vs. Thomson-Houston Electric Company, that was to have been heard last Monday before Judge Colt, has been deferred, the Judge having notified the respective parties that he could not hear the case that day.

There has been an interesting and exciting telegraph tournament in this city during the present week. The first prize was won by Mr. A. F. Booth, telegraph operator on the Lynn *Daily Item*.

After a series of inquiries, investigations and hearings, supplemented by an extended European trip undertaken by one or two members, the Rapid Transit Commission for this city has presented to the City Council a most elaborate report, setting forth in detail what conclusions have been arrived at for the solution of the rapid transit problem. The estimated cost of the plan most favored by the commission is put at $9,000,000. The report has been submitted to the city engineer, who, after a searching analysis, declares that the scheme cannot possibly be carried out for less than $18,000,000 or thereabouts. Such a difference has roused Mayor Matthews's ire, and he has been saying some pretty strong words about the work of the commission this week. Rapid transit seems as far off as ever from Boston.

During the years 1887 and 1888 the Boston Heating Company erected an extensive plant on Atlantic avenue, and built some four miles of underground conduits of a most substantial character, wherein its pipes were laid. Some $1,250,000 were expended on the enterprise, but after being in business a few months the system gave out so completely for various reasons that the company had to give up their enterprise, which had begun under the most promising auspices. Since that time until recently nothing was done with the extensive plant. At last the whole plant was sold at auction, and the heating station has been entirely dismantled. Now the city council has authorized the defunct Heating Company to transfer to the New England Telephone and Telegraph Company its entire system of conduits, pipes and manholes, also the right to make such changes in the acquired system as may be necessary to adapt it for the use of the Telephone Company in laying wires and cables therein, the Telephone Company to file with the Superintendent of Streets a plan showing the location of the acquired underground system.

The Massachusetts Institute of Technology is entitled to rank as one of the foremost scholastic and scientific institutions in the country. For many years it has been turning out from its laboratories and class rooms hundreds of promising young men who are destined to make names for themselves and to fill leading positions in those great undertakings that are to carry still nearer the front of civilization the United States of America. During the present year the students will have for use in their laboratory instruction in strength of materials some very powerful testing machines, for among other apparatus the laboratory now contains an Emery testing machine of 300,000 pounds capacity, a machine of 100,000 pounds capacity for testing full-sized wooden and iron beams of 27 feet span and less ; a torsion machine capable of breaking, by twisting, a wrought-iron shaft three inches in diameter ; a rope-testing machine capable of breaking a six-inch hemp rope ; a 50,000 pounds tension testing machine, and machines for testing cement and wire. There has also just been added a Blake duplex pump, having a capacity of 1,000 gallons a minute, a Davis plunger pump, two water motors and an indicator tester.

The medical profession in this district are in a state of excitement over an electrical device invented for their special use by a member of the profession, and orders for the same are being received daily. For dealing with contagious and other dangerous diseases this apparatus is going to offer an unerring safeguard.

Canadian Notes.

The Toronto Street Railway Company are busily engaged in laying new and heavier rails on the streets where they have not yet run trolley cars. Before the winter sets in the whole system will be converted into electricity.

The Lake Shore & Mimico Electric Railway is completed to New Toronto, and the extension was opened on Friday.

A force of 55 men is engaged laying the tracks for the electric railway in London, west. The work is well advanced and the early completion of the road is expected.

A meeting of the shareholders of the Hamilton, Grimsby & Beamsville Electric Railway was held last week for the purpose of appointing a permanent board of directors and placing the company on a proper business basis. The shareholders appointed the following gentlemen directors of the company: C. J. Myles, J. T. Middleton, E. Freeman, J. McRoberts, J. Bradley, Walter Grieve and H. S. Martin. The directors then appointed the following officers: President, Mr. C. J. Myles; vice-president, Mr. J. T. Middleton; secretary, Mr. Adam Rutherford.

The experiments in opening and closing the lock gates of the Beauharnois Canal by electricity have proved very successful, and it has been decided by the department to utilize this motive power, not only on the Soo Canal but also on the Soulanges Canal.

The Port Arthur Electric Railway is now completed. It connects the three towns, Port Arthur, Fort William and West Fort William, and is eight miles in length. An hourly service will be inaugurated between the three towns.

There are rumors afloat to the effect that the Toronto Electric Light Company have secured control of the Hamilton Electric Light Company, and judging from indications it is not unlikely the case.

At a meeting the other day of the Galt and Preston Street Railway Company it was unanimously decided to operate the road by electricity.

C. F. Stillwell, manager of the Edison Lamp Works at Hamilton, which has gone to Peterboro, intends organizing a new company, and expects to start with 40 or 50 hands.

The brick work of the General Electric Company's new power house on York street, London, is about completed. The smoke stack is the tallest in the city.

Mr. D. H. Keeley, Acting Superintendent Government Telegraphs, has just returned from the Gulf of St. Lawrence, having seen to the repair of the cables to the Magdalen Islands and St. Paul's Island, as well as the laying of a new short line at Anticosti.

The Auer Incandescent Light Company of Montreal, which has been in one trouble after another ever since the Customs officers took charge of the establishment, on the ground that the company had defrauded the customs by undervaluation, furnished a new sensation the other day. J. Brooks Young, one of the directors, and H. J. Bell, general manager, were arrested at the instance of Mr. A. O. Granger, the suspended general manager and principal promoter, upon a charge of conspiracy. The conspiracy consists in alleging that Mr. Granger forged a transfer of 500 shares of the stock. The two gentlemen were released on $500 joint bail, and the case comes off before Judge Dugas next week.

The electric light, gas and telephone companies of Toronto have this year, for the first time, been assessed on their mains, poles and wires. In the case of the Toronto Electric Light Company, this will mean, says Manager Wright, an increase of taxation from $1,200 to about $7,000 per year, and will take one-fifth of the company's net income to pay taxes. If the assessment stands, he declares he will close the machine shop, in which twenty heads of familes are now employed, and purchase all necessary supplies from Peterboro instead of manufacturing them in Toronto.

The annual meeting of the shareholders of the Standard Light and Power Company of Montreal was held in that city on the 27th ult. The Standard Light and Power Company succeeded to the St. Henri Company, and now it is amalgamated with the Citizens' Light and Power Company. The Citizens' Company does the lighting, whereas the Standard Company has the railway privileges. The Standard Company has sold its gas privileges to the John Coates Company, which has received a franchise. The shareholders are yet to decide what is to be done with the railway privileges.

General News.

What is Going on in the Electrical World.

Richmond, Va.—The Richmond Railway and Electric Company has nearly completed the work on the new electric line which is to run to Barton Heights.

Louisville, Ky.—Electric cars are now running on the Bank Street line, and it is probable that the East Walnut Street Railway will soon be equipped with electricity.

Titusville, Pa.—Interest is being revived in the projected line of electric railway between Meadville and Titusville. The line is strongly advocated by the local press.

Wheeling, W. Va.—Work on the Wheeling and Elm Grove Company's Electric Railway through East Wheeling is still awaiting the action of the city council.

Elizabeth, N. J.—The board of freeholders have granted a franchise for the introduction of the trolley system in this city and through Union County to the Consolidated Traction Company.

Alden, N. Y.—A survey has been made through this place for the proposed trolley line from Lancaster to Rochester. The line takes in nearly all the villages lying back from the railroad.

San Antonio, Tex.—The San Antonio Street Railway Company has purchased the Citizens' Electric Railway, and Superintendent Greer of the San Antonio Company is now in charge of both systems.

Port Jervis, N. Y.—Parties from Scranton, Pa., were in town last week looking over the ground for a proposed electric street railway, and there is a probability that such a road will be built next spring.

Savannah, Ga.—The mayor has imposed fines amounting to $2,000 upon the Electric Railway Company for failing to comply with the provision of the ordinance requiring that street railway tracks be graded.

Pittsburg, Pa.—An electric railway line between Steubenville and Pittsburg for passengers and freight is advocated on the ground that it would be of great convenience to a numerous farming population.

Middletown, Conn.—The Schuyler Electric Company's shops here, which have been practically shut down for two months, will reopen soon. The company's affairs are being reorganized and the office salary list is being cut down.

Montreal, Can.—A charter has been obtained for an electric railway line at Cote St. Antoine to run from the north of the Cote St. Antoine road to the boundary of Cote des Neiges, including some mountain grading of 10 per cent.

Wilmington, Del.—A committee, consisting of Dr. J. H. Wilson, S. B. Smith and H. A. Newland, has been appointed to confer with the Alms House Committee on the subject of electric lighting for the county and State institutions.

McKeesport, Pa.—The White Electric Traction Company has assigned to Robert R. Hammond and William E. Tustin, under date of October 6, 1893. It conveys all the real estate and also all goods, chattels and effects and property of every kind.

West Chester, Pa.—A preliminary survey of the projected electric railway between West Chester and Philadelphia has been made. The line will pass through a number of towns in Chester and Delaware counties, and will be twenty-three miles long.

Los Angeles, Cal.—At the foreclosure sale of the Pacific Railway Company's property (cable road) on the 4th inst., E. P. Clark, general manager of the Consolidated Electric Company, bought the machinery and appurtenances offered for the sum of $17,476.30.

Batavia, N. Y.—The *News* is authority for the statement that an electric railroad from Depew to Batavia is to be constructed; a corps of engineers are now at work surveying a line to Batavia running parallel with and but a short distance from the new Buffalo road.

Orange, N. J.—An ordinance granting a franchise to the Newark and South Orange Railroad Company to run cars through South Orange was passed by the board of trustees on the night of the 6th inst.; immediately men were set at work setting poles and stringing wires, and at 10:45 the following day a car was sent over the line.

Defiance, Ohio.—The Defiance Electric Light and Power Company has been reorganized with the following officers: President, S. L. Nelson; vice-president, W. B. McKinley; secretary and treasurer, Frank L. Smith; board of directors, Henry Smith, F. L. Smith, C. C. Rush, of Bay City, Mich, W. B. McKinley and S. L. Nelson.

Meriden, Conn. The street railway company has decided to put in the Thomson-Houston system of electric cars and work will be begun next week. The majority of the stock of the company has been sold to a Philadelphia syndicate represented by Walter F. Douglass. Electric cars will be running by December.

Hartford, Conn.—An incandescent lamp invented by Henry Green, of this city, is being tested in Springfield, Mass. Some of the lamps already completed are of 52 and 110 volts; they are each of 16 C. P., and show an efficiency of three volts per candle. The lamp, it is reported, has been received with great favor in Springfield.

Berlin, Ger.—The Berlin Rapid Transit Commission have accepted a definite plan for the new railroads projected for Berlin, and the Werner-Siemens Electric Company will do most of the work. In the less busy parts of the city the cars will run in the street; in other parts on elevated roads; and in the busiest part of the metropolis they will dip into an underground tunnel. The cars will all be run by storage batteries.

Jersey City.—Proposals and bids will be received by the board of chosen freeholders of Hudson County for the erection and completion of the electric light wiring for the new lunatic asylum building at the county farm, Snake Hill, at their meeting to be held at the Court House, Jersey City, Thursday, October 19, 1893, at 4 o'clock P. M. Plans and specifications and forms of contract can be seen at the office of the board, next the Court House, and at the office of H. Kreitler, 55 Montgomery street, Jersey City.

Myersville, Md.—At a recent meeting of the stockholders of the Catoctin Valley Electric Railroad and Power Company, held here, the following directors were elected: Geo. W. Jacobs, Jr., T. E. Bowne, C. F. Flook, D. V. Harp, G. W. Wachtel, E. J. Smith and Edgar L. Miller. The intention of the company is to build an electric road from Middletown via Myersville to a point in the northern part of Middletown Valley, twelve miles in length. The contract for the building of the road was awarded to the Hughes & Rigby Engineering Company of Baltimore.

Vicksburg, Miss.—The Weaver-Campbell Electric Company, of this city, made a test a few days ago over the Valley route wires, between the general office of the road in New Orleans and the train dispatcher's office in this city, of the Magno-Secrograph, an invention of J. P. Weaver, said by the local press to be of "indispensable value to brokers, railroad magnates, etc., and destined in the judgment of experts to revolutionize certain branches of telegraphy." The test was of considerable duration and the new instrument sustained the claims made for it.

New York.—At the annual meeting of the Western Union stockholders, held on the 11th, President Eckert's report was presented. The capital stock was shown to be $95,320,000. Revenues during the year, $24,978,442; expenses, $17,482,405 During the year there were added to the company's system 360 miles of poles, 30,000 miles of wire and 378 offices. The six vacancies on the board of directors, caused by death and resignations, were filled by the election of the following: John Jacob Astor, Oliver Ames 2d, George Bliss, Louis Fitzgerald, C. Sidney Shepard and J. B. Van Every.

Brooklyn, N. Y.—The trustees of the big bridge spanning the East River have been making investigations into the relative efficiency of cable and electric traction systems and are said to be in favor of substituting electrical motive power for the cable on the bridge road.—The Brooklyn Young Men's Christian Association has outlined for the winter season of 1893-94 a course of lessons and lectures on the "Theory and Practice of Electricity," which promises to be unusually attractive as well as instructive.—One of the big fly-wheels in the power-house of the Atlantic Avenue Railroad Company burst on Wednesday night last, injuring three of the employees and a woman and doing damage estimated at $40,000.—The Grand street line of the Brooklyn City Road, which runs to Maspeth, Newtown and Corona and its branch to Calvary Cemetery, by the way of Humboldt street and Meeker avenue, will be equipped with the trolley on November 1. Nearly all the wires have been strung, the men broken in as motormen and the new cars are ready.

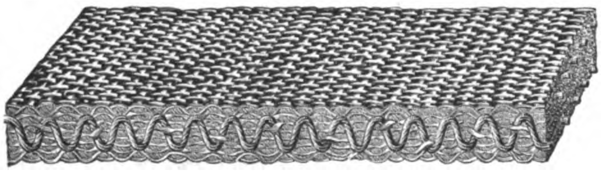
Baltimore, Md.—In the Female House of Refuge in this city an electric system has been introduced which will greatly lessen the danger to the lives of the inmates from fire. The women are locked up in their rooms at night, and under the old system many of them would undoubtedly perish if the building were burned down. Should a fire occur now, the matron by moving the switch to the point marked "Fire" releases all locks on the doors leading to the fire escapes, also all locks on the doors of the refractory cells, located in the basement, and sets the different fire alarm bells going, so that no accident may be caused by delay.—The Brush Electric Light Works building was destroyed by fire on the night of the 13th.—The *Herald* says the expedition with which the old horse car lines in Baltimore have been changed into cable and trolley roads surprises everybody. It is yet only three years since work was begun on the first cable road, and already twenty-one lines have been fitted out with rapid transit and some of them are new routes which were not even projected in 1890. But this unheard of activity in pushing forward rapid transit lines is likely to be duplicated many fold in the Maryland counties within a brief period. There are the projected roads to Washington, the extension of lines to Sparrow's Point and Lutherville, not to mention an air line road across Anne Arundel County to Annapolis and Bay Ridge. But the great centre of electrical railway development is to be found in Frederick County.

Maddox Cotton and Wire Belting.

The strong claims of merit and superiority made for this belting are based on the material it is made of, the way these are woven together, and the way the belting is made. It is made of cable soft steel wire and cotton, woven solid together, making it strong and durable. The cables of wire are each composed of six soft steel wires, twisted together like a cable. The cables are laid lengthwise in the belting, about one-eighth of an inch apart, forming part of the warp, the cables composing about one-half of the warp, the rest of the belt being composed of strong, tough cotton yarn, spun especially for this purpose.

The cotton filling or woof is woven in solid with the warp, the process of weaving causing the cables of wires to become corrugated in form, or doubled back and forth through the thickness of the belting, the corrugations being about one-eighth of an inch apart, and about as long as the belts are thick, the cotton woof being woven in solid in the meshes or corrugations of the cable. The weaving of the cotton and wire solidly together completely and thoroughly covers up the wires with the cotton, so that the wire cables do not come in contact with the pulleys; the wire cannot be seen in the belting except when it is cut so as to expose it. The rough surface given to the belting by the cotton forms an elastic, rough face that prevents any air cushions forming between the belt and pulley. It is claimed the belting is absolutely waterproof, being thoroughly filled with a permanent waterproof material. It is also claimed that it is not affected by water, steam, dampness, moisture, heat, dryness, oils, grease, acids or chemicals or the vapors of them, changes of climate or weather, dirt or dust.

Some interesting tests of the durability of the Maddox wire and cotton belts have recently been made. In one case a 5-inch belt, 26 feet long, and traveling 2,200 feet per minute, was used on a band veneer saw. The belt crosses immediately under the saw at the point where the dust from the saw fell on it, the conditions being so very unfavorable that leather or rubber belts would last but a few weeks. The Maddox belt, in this case, has run three months without showing any signs of wear. Government tests of the Maddox belt are about to be made at the ordnance shops of the United States Navy Yard at Washington, under the supervision of Commodore Sampson, Chief of the Bureau of Ordnance. Two belts, each 46 feet long by 8 inches wide, are to be tested on blowers in the forge shops, while other belts are to be tested on woodworking machines. Mr. H. N. Green, the general agent of this belt, whose temporary headquarters are at 254 Fulton street, Brooklyn, N. Y., has received many highly complimentary opinions of the Maddox belting, and looks for its use in all departments of trade.



Maddox Cotton and Wire Belting.

Columbus Electrical Machine Works.

The business of this house was established about eight years ago by the Minott Electrical Machine Company and came into the hands of the present owners in April, 1893. The firm consists of J. M. Keleher and J. Hickey and was organized with a capital of $20,000. The large two-story building occupied by them is equipped with a most complete line of modern machinery adapted to their business. The business consists in the manufacture of dynamos, motors, platers and engine governors. They also manufacture all kinds of electrical appliances, as well as pulleys, shafting and hangers of every description, and plates for electrical silver and nickel plating. They also design steam plants, construct electric light plants and repair electrical machinery. They pay special attention to the installation of isolated plants. Mr. Keleher is a man of large experience as a machinist, having been connected with the McNamor machine works at Newark, O., for twenty-five years, during which time he acted as their superintendent for fourteen years and did most of the designing and perfecting of their machines. Mr. J. Hickey is also a thoroughly experienced machinist. He has been in this line of business for about thirty years, and was seven years with Whitely, Fassler & Kelley, of Springfield, O., where he had charge of the tool room and designed and superintended their special work. The office of the firm is located at No. 56 Vine street, Columbus, O. These gentlemen have displayed a great deal of energy in the establishment of their new enterprise and are well worthy of the success which they have achieved. Persons desiring work in the line would do well to give them a trial.

The Mica Insulator Company.

The Mica Insulator Company of New York and Schenectady will make a fine display at the meeting of the American Street Railway Association in Milwaukee.

This will be the first time this company has made an exhibition of micanite. It will be of interest to all who are in need of a perfect insulator. Micanite is surely and steadily being adopted as a reliable insulator not only in the United States but in Europe.

This company has made several important improvements in the method of manufacturing, and they are very happy to say that micanite of to-day is far ahead of what they put on the market when they first began business.

The exhibit will be in charge of Mr. Charles W. Jefferson, their manager, who is thoroughly posted on insulation. Mr. Jefferson was for several years manager of the insulating department of the Edison General Electric Company at Schenectady.

COMMERCIAL PARAGRAPH.

The Metropolitan Electrical Company, offices 319-320 Manhattan Building, and salesroom 307 Dearborn street, recently organized, will make an announcement shortly as to the scope and general plan of the company. Mr. Wm. H. McKinlock, of this company, feels that the outlook for business is encouraging, and sees the promise of liberal support for a good, strong company, conservatively managed. Evidence of this fact is fast multiplying. In the meantime they are receiving orders for general supplies and N. I. R. Wire, with which they are generously stocked.

INCORPORATIONS.

The Egan Electrical Company, Chicago, Ill.—to manufacture and use all kinds of electrical machinery, devices, appliances, etc. Capital stock, $60,000. Promoters: R. L. Duval, Charles E. Egan, George P. Jones and B. C. Caldwell.

The Overbrook Electric Company, Philadelphia, Pa.—to supply light, heat and power by means of electricity to the public in Philadelphia. Capital stock, $10,000. Promoters: John W. Paul, Jr., Edw. T. Stotesbury, Philadelphia; Herman Wondell, Wayne, Pa.

The Fullner-Danhoff Electric Company, Chicago. Capital stock, $5,000,000. Incorporators: Franz Fullner, A. B. Coon, Henry A. Gates, William B. Keep.

The Electric Heat Register Company has been incorporated, with a capital stock of $40,000, by J. H. Ames, of St. Paul, Minn. A. S. Robbins, W. F. Decker, W. R Sweatt and C. H. Magnuson, of Minneapolis.

The Enid and Perry Railway Company, Guthrie, Okl.—to to build an electric railway between six towns in Enid and Perry Counties, in the Cherokee Strip, with a total length of forty miles. Capital stock, $500,000. Incorporators: E. L. Dunn, R. W. Patterson, C. O. Wood and J. W. Thompson, of Enid, and James A. Pearce, of Denver, Col.

Articles of organization have been prepared incorporating in Hartford the Connecticut Royal Arc Electric Company, a branch of the Royal Arc Electric Company of New York City. This company will handle a new incandescent arc light.

The Hillsboro Electric Light and Water Company, Hillsboro, Ore.—to maintain and operate an electric light and water plant in Hillsboro. Capital stock, $40,000. Promoters: Harry V. Gates, Duncan Kankin, Helen M. Gates, W. E. Pruyn, Hillsboro.

The Lancaster Investment Company, Seattle, Wash.—to build and operate street and other railways, electric light plants, etc. Capital stock, $100,000. Geo. H. Danner, M. F. Phantz, D. L. Hamaker, Manheim, Pa.; J. F. Eshelman, Chas. William Cropp, Jas. Skinner, Seattle.

The Eureka Brick, Tile and Electric Company, Eureka, Ill.—to manufacture and operate brick, tile and electric plants. Capital stock, $50,000. Promoters: J. M. Deck, J.A. McGuire, W. S. Allen, Albert Gudeman, Samuel Gudeman, W. A Davidson, N. B. Crawford.

ELECTRICAL PATENT RECORD.

Letters Patent Issued Sept. 26-Oct. 3, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

505,457. Trolley-Wire Support. Lucius T. Gibbs, Milwaukee, Wis. Filed Oct. 15, 1892.
505,605. Closed Conduit for Electric Railways. Geo. W. McNear, Oakland, Cal. Filed Aug. 1, 1892.
505,686. Controller-Roller for Electric Cars. Ernest P. Warner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 21, 1892.
505,687. Automatic Passenger Train Annunciator and Alarm. Alfred E. Watts, Duluth, Minn. Filed Jan. 18, 1892.
505,841. Conduit Electric Railway. Lawrence A. McCarthy, Brooklyn, N. Y. Filed Feb. 6, 1893.
505,994. Electro-Conducting Bearing for Trolley or Other Wheels. Elmer A. Sperry, Chicago, Ill., assignor to Frank R. Greene, same place. Filed Sept. 17, 1891. Renewed Feb. 21, 1893.
506,001. Controlling Device for Electric Railway-Cars. William P. Coldren, Lebanon, Pa., assignor of two-thirds to Jacob M. Shenk, same place, and William H. Conrad, Reading, Pa. Filed April 22, 1893.
506,043. Trolley-Wire Support. Maurice Hoopes and Oscar S. Hertzog, Lynn, Mass. Filed July 1, 1893.
506,124. Electric-Railway System. Harry A. Lewis, Norristown, Pa., assignor of three-fifths to John T. Dyer, same place. Filed March 3, 1893.
506,149. Electric-Trolley Wire Crossing. Edgar P. Binford, Cincinnati, Ohio. Filed Nov. 3, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

505,585. Adjustable Supporter for Electric or Other Lamps. Otis C. White, Worcester, Mass., assignor of one-half to George E. Francis, same place. Filed Mar. 31, 1893.
505,913. Incandescent Electric Light. Henry D. Burnett, Lynn, and Samuel E. Doane, Swampscott, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed June 27, 1892.

DYNAMOS, MOTORS, ETC.

505,505. Multiphase Motor. Louis Bell, Boston, Mass., assignor to the General Electric Company, same place. Filed June 14, 1893.
505,539. Field-Magnet Core for Dynamos or Motors. George S. Strong, New York, N. Y., assignor to James N. Gamble, Cincinnati, Ohio. Filed Feb. 3, 1892.
505,594. Controlling Device for Electric Motors. Chas. G. Curtis, New York, N. Y. Filed Oct. 22, 1892.
505,622. Dynamo-Electric Machine. Arthur S. Atwater, Cleveland, Ohio, assignor to the Atwater General Electric Company, same place. Filed Jan. 23, 1893.
505,665. Dynamo-Electric Machine or Electric Motor. Robert Lundell, Brooklyn, assignor of two-thirds to Edward H. Johnson, New York, N. Y. Filed Oct. 31, 1892.
505,729. Armature for Electric Motors. William J. Sherwood, Ashtabula, Ohio. Filed April 16, 1891.
505,783. Electric Motor. Ralph Ashley, Philadelphia, Pa., assignor of one-half to Charles W. Kennedy, same place. Filed May 20, 1893.
505,859. Alternating-Current Motor. William Stanley, Jr., and John F. Kelly, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed June 8, 1892.
505,914. Regulator for Dynamos. William H. Elkins, Cambridge, Mass. Filed Nov. 21, 1892.
505,926. Armature for Electric Machines. Albert Schmid, Pittsburg, Pa. Filed Nov. 3, 1893.
505,927. Alternating-Current Generator. Albert Schmid, Pittsburg, Pa. Filed Nov. 3, 1892.
505,928. System of Electrical Distribution. Charles P. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Sept. 28, 1892.
505,957. Armature. Martin Rahner, Union, N. J. Filed Dec. 7, 1892.

BATTERIES.

505,467. Secondary Battery. Isidor Kitsee, Philadelphia, Pa. Filed May 23, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

505,628. Duplex Telephony. William Marshall, New York, N. Y. Filed Feb. 28, 1892. Renewed July 8, 1892.
505,730. Telephone-Circuit. Theodore Spencer, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Feb. 20, 1893.
505,917. Transmitting Telephone. Silas W. Holman, Boston, Mass. Filed May 4, 1893.
506,132. Coin Controlled Telegraphic Call Apparatus. Graydon Poore, Putney, England. Filed March 29, 1892.
505,724. Coin Controlled Electric Call Apparatus. Graydon Poore, London, England. Filed May 16, 1892.

ALARMS AND SIGNALING APPARATUS.

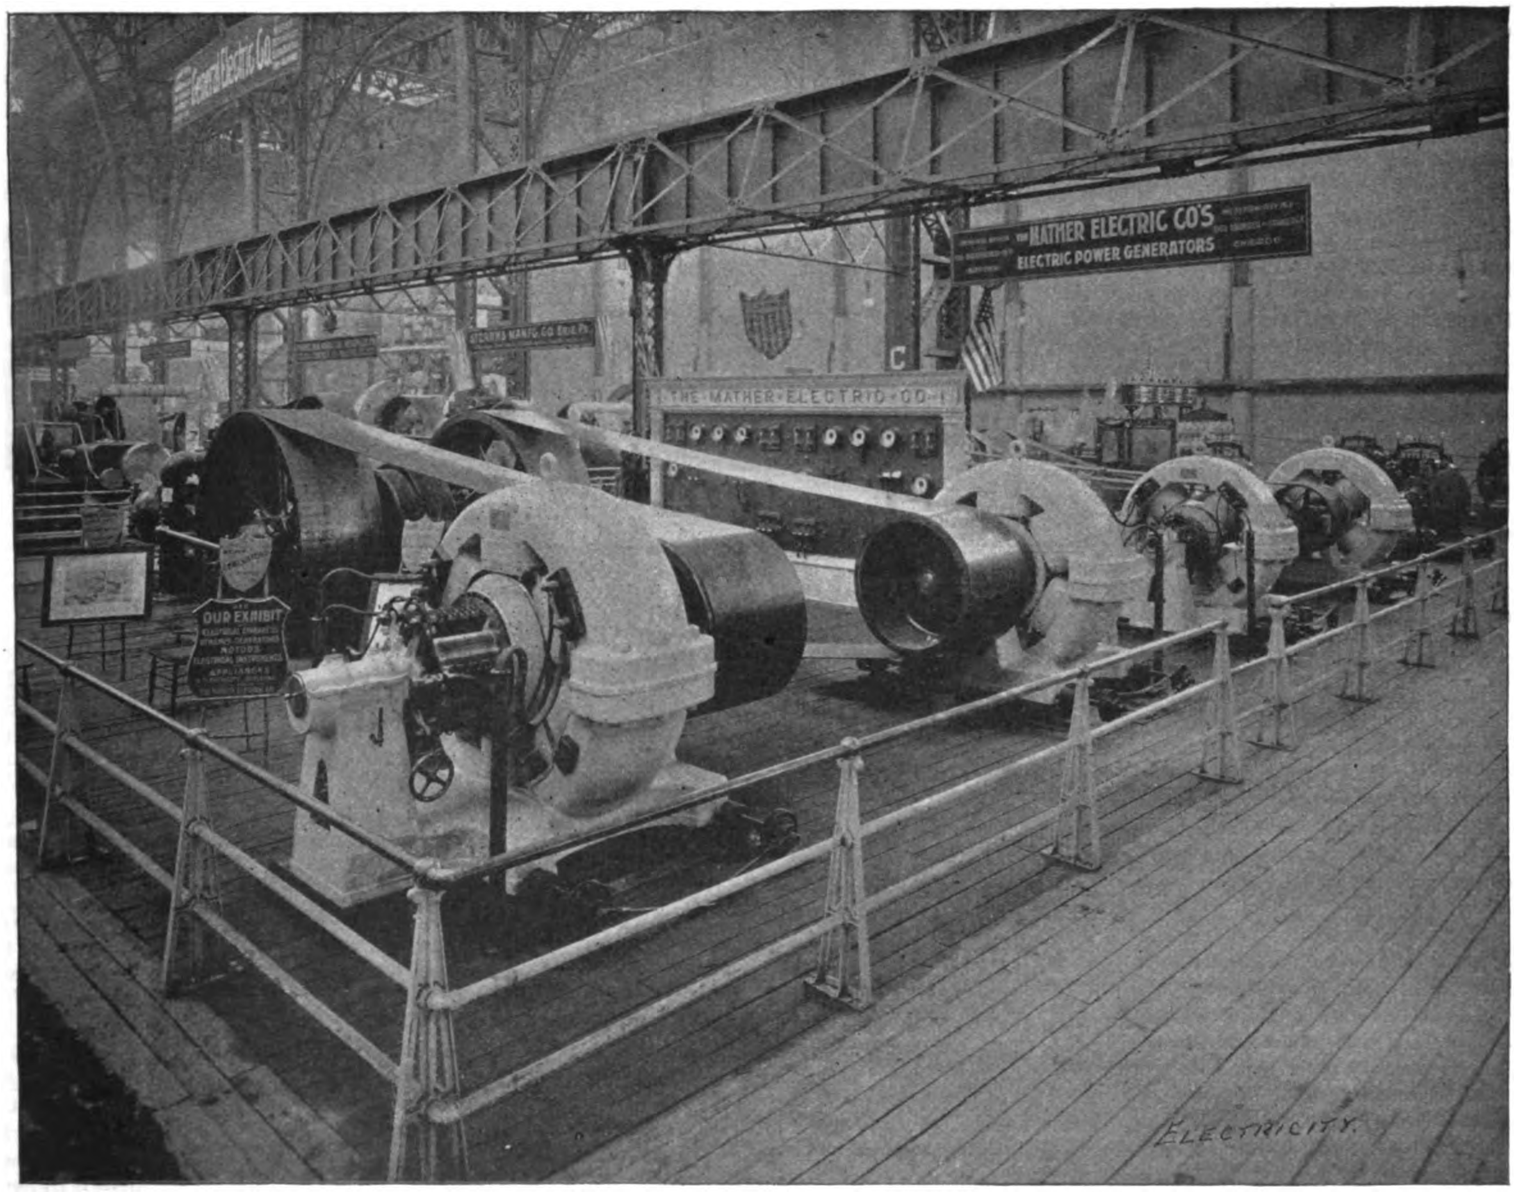
505,819. Fire-Alarm System. Harry T. Downs, New York, N. Y., assignor of one-half to Loren N. Downs, same place. Filed Oct. 1, 1892.
505,834. Fire-Alarm. August Crastin, Cleveland, Ohio. Filed Jan. 6, 1893.
505,833. Contact for Signaling to Cars. Frank E. Kinsman, Plainfield, N. J. Filed May 26, 1892.

MISCELLANEOUS.

505,561. Electrical Connection. William I. Smith, Memphis, Tenn. Filed April 19, 1892.
505,669. Means for Preventing Railroad Collisions. Eduardo M. de Monte and Carl Jost, Bombay, India. Filed Oct. 28, 1892.
505,775. Apparatus for Molding and Pressing Carbons. Louis B. Marks, New York, N. Y., assignor to the Washington Carbon Company, Washington, Pa. Filed Oct. 26, 1892.
505,798. Manufacture of Cables for Multiple Switchboards. Oro A. Bell, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Nov. 7, 1892.
505,808. Electric Time Cut-Out. Frank Beland, Cairo, Ill. Filed July 8, 1893.
505,822. Protector for Pipes from Powerful Electric Currents. Frederic Egner, St. Louis, Mo. Filed June 17, 1893.
505,838. Lathe for Dressing Commutators. James A. Mebane, Wytheville, Va. Filed Jan. 28, 1893.
505,860. Method of Working Condensers. William Stanley, Jr., John F. Kelly and Cummings C. Chesney, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed March 18, 1893.
505,895. Apparatus for the Electrolytic Production of Soda and Chlorine. Elisha B. Cutten, New York, N. Y. Filed Dec. 30, 1891.
505,911. Rheostat. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Dec. 22, 1892.
505,912. Cleat for Holding Insulated Electric Wires. Elisha W. Buffinton, Fall River, Mass., assignor of one-half to Albert F. Dow, same place. Filed June 1, 1893.
505,916. Insulating Compound and Method of Manufacturing the Same. Joseph Hoffman, Schenectady, N. Y., assignor to the General Electric Company of New York. Filed Dec. 2, 1892.
506,002. Insulating Support for Metallic Circuit. Alfred C. Cousens, Boston, assignor, by mesne assignments, to Charles A. Stone, Newton, Mass. Filed May 6, 1893.
506,034. Insulating Joint. Samuel W. Burtchaell, San Francisco, Cal. Filed June 20, 1892.
506,066. Means for Determining the Presence and Intensity of Atmospheric Electricity. Jesse Opperman, St. Louis, Mo. Filed Feb. 15, 1893.
506,092. Electrical Switch. Carl O. C. Billberg, Philadelphia, Pa. Filed July 23, 1892.
506,169. Electric Elevator. Ernest R. Esmond, New York, N. Y. Filed Feb. 21, 1893.

ELECTRICITY.

VOL. V. NEW YORK. OCTOBER 25, 1893. CHICAGO. No. 15



MATHER ELECTRIC COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 174.)

World's Fair Notes.

The Mather Electric Company's Plant in Machinery Hall, Section C.

This exhibit contains two compound wound electric power generators, capacity of 225 K. W. each, and working at a potential of 550 volts 450 revolutions per minute, and two compound wound electric power generators, capacity of 120 K. W. each, and working at a potential of 550 volts 525 revolutions per minute.

The 225 K. W. generators are 6-pole machines with field magnets and armature supports cast in one piece without joints except between the upper and lower half of the field.

The winding of the armature is such that there are only two paths for the current through the armature, and yet opposite bars of the commutator are connected and so maintained always exactly at the same potential. The commutators are cross connected, so that the opposite bars are maintained always at the same potential, therefore it is possible to use either all the sets of brushes or any two sets, as may be desired.

The generators are mounted on sliding iron bases fitted with four screws, connected together in pairs by means of a chain, and operated by ratchets so that the generator can be kept in perfect alignment and the tension of the belt regulated.

The base frames are firmly bolted down to the foundations, which in this case are made of heavy timber and hard burned brick laid in Portland cement.

The four generators are connected to one set of bus-bars, so that all the machines can be operated in multiple when desired.

The switchboard to which these generators are connected is made of slate slabs set in a steel frame, making the switchboard self-contained.

On it are mounted four rheostats, four triple pole switches through which the generators are connected to the bus-bars, four ammeters which record the quantity of current generated by each machine, one voltmeter which is so connected by means of their voltmeter switch that readings may be taken from either generator or from the bus-bars by moving the switch bar on the respective points, one differential indicator which may be connected by means of their indicator switch to any one of the generators when it is desired to throw one or another of the generators into circuit while one or more are in operation, and this instrument indicates correctly when the machine to be thrown in circuit attains the proper potential.

There are four double pole single throw switches through which the circuits are connected to the bus-bars, four ammeters which show the quantity of current used on each circuit, and the circuits are protected by means of double pole safety cutouts which carry a fusible strip of suitable capacity, and are further protected by means of the automatic adjustable circuit-breakers mounted on separate frames behind the switchboard.

The switchboard is encased in a massive framework of pure Doric style, and finished in white enamel and gold.

The bus-bars and all the connections between the switches and instruments are of the best quality of copper, of ample capacity, symmetrically mounted on the back of the switchboard, all polished and lacquered.

These generators have been supplying the current for operating the motors in the Mines and Mining Building, Agricultural Building, the Movable Sidewalk on the pier, the Mather Electric Company's exhibit plant in the Electricity Building, and other motors.

The generators are all finished in white and gold, the whole plant presenting a handsome and imposing appearance.

These power generators are particularly adapted for street railway work, mining work and factory power plants, their regulation being superior and their efficiency at the highest point.

The Hicks-Troy Door Opener.

The Hicks-Troy door opener, which we illustrate herewith, has turned out to be one of the most novel and interesting exhibits in Electricity Building. Owing to some difficulty in getting the proper machinery, the firm were unable to complete their exhibit for some months after the Fair opened. Since they have completed the arrangement of the doors, the exhibit has been literally besieged by visitors who desire to see "a door opened by electricity." The operation and mechanism are extremely simple. The doors are hung on ordinary hinges with spring attachments which have a tendency to throw the door open. Electricity is brought into play to close and hold the door shut. This is accomplished through the means of a small electric motor which is mounted in the neighborhood of the door. A small cord is attached to an arm extending out from the top of the door, the cord then passing over a pulley on the door frame to the motor, whose function is to wind up the cord after the door has opened. The electrical mechanism is put in operation by a person who desires to pass through the door stepping on a mat which closes the circuit and allows the springs to come into operation. As soon as the mat is relieved of the pressure the current is interrupted, but the swinging of the door has closed a magnetic switch in connection with the motor which operates to wind up the cord and thereby close the door.

THE HICKS-TROY DOOR OPENER.

The invention is credited to Messrs. R. F. Troy and O. H. Hicks, of Chicago, who are showing several of the doors in operation in the southeast gallery of the Electricity Building at the Fair.

The New York Electrical Society.

The 153d meeting of the New York Electrical Society will be held at Columbia College on Tuesday, October 31, at 8 P.M.

Mr. D. McFarlan Moore will lecture on "Electricity in Advertising," and will describe the latest developments in this branch of electrical application.

An Electrical Man in Politics.

Mr. James A. Roberts, of Buffalo, who is widely known in the electrical field, has been nominated on the State ticket for Comptroller. Mr. Roberts, who for some time represented Erie County in the Senate and Assembly, settled in Buffalo some years ago, where he went to take the position of superintendent of a school at that place. He subsequently studied law, in which field he has built up a large practice. He is widely known among electrical men, on account of his numerous connections in this business, being one of the founders of the old Thomson-Houston Company of Buffalo, vice-president of the Buffalo and Belleview Street Railway Company, vice president of the Buffalo and Niagara Falls Electric Light and Power Company, and secretary of the Buffalo General Electric Company. Mr. Roberts is eminently qualified for the office to which he is nominated, and his electrical friends wish him every success in his coming campaign.

DeLand's Synoptical Index.

The excellent index of current electrical literature which has formed a leading feature of *Electrical Engineering* is to be still further extended in its scope and will hereafter be printed on separate sheets, each sheet to be devoted to a single subject.

This arrangement is with a view to filing the index under each general head separately if desired, and judging from the thorough character of Mr. DeLand's index heretofore, the new system promises to furnish the most complete and best arranged synopsis of electrical literature ever published.

The value of Mr. DeLand's work in this direction has been thoroughly recognized from the start, and ELECTRICITY wishes him every success in the prosecution of his new project.

Electricity in addition to its other manifold uses is a sanitary agent. When Professor Tyndall was experimenting with atmospheric dust in his researches on the origin of the lowest forms of life, he found that an electric discharge passed through a dusty atmosphere purified it by causing the minute particles to settle. And long before these researches, it was commonly said and believed that a thunderstorm purified the air. Thus a scientific foundation is found for the popular belief, and the lightning flash takes its place as an accredited sanitary agent.

The Milwaukee Convention.

Twelfth Annual Meeting of the American Street Railway Association.

The twelfth annual meeting of the American Street Railway Association was held in the Assembly Hall of the Milwaukee Industrial Exposition Building, October 18-20.

WEDNESDAY'S PROCEEDINGS.

The president called the meeting to order and introduced Mayor John C. Koch, of Milwaukee, who welcomed the delegates as follows:

"It affords me great pleasure in meeting you to-day in our city and in our Exposition building. I welcome you and extend to you the freedom of the city.

"Gentlemen, you are interested in one of the great forces of modern times, which builds up large cities and gives us the convenience of rapid transit. The street railways are great factors in our progress. They relieve the large cities from being overcrowded and allow the spreading of our population over widely extended territories, thereby giving the people the benefit of fresh air in the suburban neighborhoods, which is of inestimable value to the health and happiness of the population of large cities.

"I hope this meeting will be productive of much good and have a satisfactory result. I hope also that besides the practical part of this meeting, you will enjoy your visit to our city and that friends here will take good care of you. Gentlemen, you are welcome."

President Longstreet responded briefly to the welcome of Mayor Koch, and addressed the convention as follows:

This has been a busy year in the great work of consolidation, reorganization and active progression; the financial cloud which has hung so threateningly for so many months over every industry in our land has had its retarding effect upon our particular industry, but perhaps it has affected our business in a less degree than any other branch of business employing so large a capital.

The hundreds of millions of dollars invested in urban and suburban transportation, will always be a safe investment. If, in our enthusiasm we have sometimes over-discounted the future we have only to wait a little longer period for the dividends which are sure to come.

Financial panics through which we are now passing are of irregular occurrence, yet they are sure to reappear, affecting receipts and making economies of management a subject of deep study.

In my experience, covering a period of nearly thirty years, I have found it better to keep up the quality of service at such times even at the expense of dividends for the time being; the public by a more liberal patronage will eventually more than make up the loss which would follow on the heels of a reduced and debased service; the faithful employee and the roadbed and equipment should be the last to suffer.

Economies should begin in other directions—in the purchase of supplies, in better methods of work and in improved appliances, aiming always for the best service at the least possible cost; and that, gentlemen, is the fundamental principle of the prime reason for our organization; and that is why, in just such times as we are now passing through, we should see if some plan cannot be devised which will increase the usefulness of our Association.

The statistics of our business which a dozen years ago looked so large are dwarfed into absolute insignificance by the figures of to-day, and yet the work has only just begun; very much more progress will be made in the next decade than has been made in the last, and therefore an active struggle to get the best results and to keep thoroughly "up to date" in all the details of construction, equipment and management will be worth more to our interests than can be foretold.

The report of the Executive Committee was read by Secretary Richardson, and showed that, after numerous consolidations among members, the present membership is 200 companies.

The committee congratulated the inventors, manufacturers and all others who contributed to the street railway part of the Columbian Exposition in both the Transportation and Electricity Buildings; and also congratulated the Exposition authorities on their success in having given to the world, and especially to the United States, the greatest Fair the world has ever seen.

The committee paid a fitting tribute to the memory of James W. Hyatt, of Norwalk, Conn., George D. Capen, of St. Louis, and Edward E. Denniston, of Philadelphia, members of the Association, who had died during the year.

After considering at some length the formation of the American Street Railway Industrial Association, the chief feature of which would be a two or three weeks' exhibit annually of street-railway apparatus, the committee decided that it was best to hold the project in abeyance until general business has improved.

The report of the treasurer was read, and showed receipts and expenditures during the year as follows:

Receipts	$8,763.77
Expenses	6,541.48
Balance	$2,222.29

The convention then adjourned until 8 o'clock P. M.

WEDNESDAY EVENING SESSION.

Mr. O. T. Crosby being called upon to give his opinion of the relative conditions of the power required in the generator and the engine, said in part:

The question is in regard to the proper proportion to be established between the rated capacity of dynamos and engines. I have believed for some time that the best practice is that an engine should be at least no greater in capacity than the dynamo to which it is attached. The engine will certainly not do its work as economically if it be run ordinarily at a considerably lower output than the output for which it has been calculated as a normal output. The dynamo does not suffer by any means so badly in thus being brought below its rated work. If, therefore, an engine of 600 H. P. be attached to a dynamo of 500 H. P., the man running the station will ordinarily and very properly limit the load which is thrown on the couple, since they now constitute a couple, below the capacity, as he understands it, of the dynamo rather than of the engine. He will endeavor to keep within safe limits with respect to his dynamo. In thus keeping within safe limits with respect to his dynamo he is keeping too far under the limit with respect to the engine for economical work. The dynamo is not what you should have unless it can be run at its rated load without any injury.

There is another point as between vertical and horizontal engines. I do not think the matter as far as it went this morning was presented just as it should have been. There is no difference in the machines, intrinsically, as to their value. You can make a splendid vertical engine, and you can make a splendid horizontal engine. A vertical engine as compared with a horizontal engine involves a difference in the space occupied; and space represents money investment; and there, in my opinion, is the most of the whole question. There is enough experience in the engineering practice to justify us in feeling that vertical engines and horizontal engines are almost equal in value and driving power.

The location of the station is always an important matter, especially as to the cost of conductors and the question of condensing engines. In the case of a man who is in a city with a river running through it in such shape that he can put his station near it, he will be at once led to the condensing engine.

The next paper read was the report of the Committee on Heating and Lighting of Street Railway Cars, which was received and ordered to be placed on the minutes.

The report of the Committee on Standards was called for, and Mr. O. T. Crosby, chairman of the committee, reported that no written report had been prepared; that the committee regretted not having a report ready, but it was unavoidable. The committee was continued another year.

The president announced the next business to be a report from the Committee on "Can the T Rail be Satisfactorily Used in Paved Streets?" A letter from Mr. C. Densmore Wyman, the committee on this subject, was read, in which he regretted his inability to prepare a report, owing to the demands of other duties. The president then requested a discussion of the subject by the meeting, after which, on motion, the appointment of a Committee on a Standard Rail for Street Railway Use was referred to the Executive Committee.

THURSDAY MORNING SESSION.

The first business was the reading of the paper on "Storage Batteries in Connection with Central Stations for Utilizing Surplus Energy for Lighting or Power."

The paper was read by the secretary.

Mr. Mailloux—I earnestly hope that the members will discuss this paper. As street railway men, you are all interested in getting the full percentage of your production of power. Our experience with storage batteries in this country has been negative, passive and generally unsatisfactory. It is in my opinion largely due to the fact that we have attempted to accomplish too much. Abroad it has been quite the reverse. They have made more substantial batteries, and have taken advantage of the fact that in central stations there is no objection to putting in a large amount of material to make the machinery sufficiently robust and large, even though it may have a much lower capacity for the same weight and cost. I believe that one of the most important things to be done is to get at the efficiencies of the engines under varying conditions. I submit that it is of the highest interest to know whether your engines are consuming 20 pounds of water per horse power hour or 60 pounds; and I do not think the Association could do better work than to take steps to have the fact ascertained, to find out what, for example, on a ten car road is the average consumption with a certain type of engine per horse power hour; and so on with a 20, 30 and 40 car road under the same or other conditions. There is a great difference of opinion to-day as to whether compound engines are adapted to use in central stations for railroad purposes. There is no doubt that they are the best with storage batteries, because you have a constant load, which is the ideal condition in which condensing engines can give their highest efficiency.

On motion, the report was received and ordered to be placed on the minutes.

Mr. Elmer A. Sperry then read a paper on "Traction and Street Railway Trucks" which was received and ordered to be printed.

Mr. O. T. Crosby then introduced Mr. Fritz, of the Bethlehem Iron Works, who was invited to address the meeting.

Mr. Fritz said that he was entirely unprepared to make any remarks; that he did not come to make a speech, but to form the acquaintance of the members; that he was a man of work rather than a talker; and thanking the convention for its courtesy, begged to be excused from making any remarks.

The president appointed the following gentlemen the Nominating Committee to nominate officers and select a place for the next meeting:

Messrs. Lang, of Toledo, O.; Hean, of St. Joseph, Mich.; Baumhoff, of St. Louis, Mo.; Rugg, of Pittsburg, Pa.; Stephenson, of Washington, D. C.; Lusher, of Montreal, Canada; Perrins, Trenton, N. J.

Mr. Payne, of Milwaukee, here announced that the Wisconsin Telephone Company desired to extend to the gentlemen in attendance at the meeting the use of its long distance wires, running to all sections of the country, free of charge, for business or social purposes.

The announcement was greeted with applause.

Mr. Payne also announced that the Bell Telephone Company extended an invitation to the delegates to visit their exhibit at the World's Fair, where they would be pleased to show the appliances and the improved methods of the telephone art. Mr. Payne said he had no doubt it would be a great benefit to all to know more about the intricacies of that very delicate instrument the telephone. The telephone system and the street railway system do not always get on well together, unless they are properly built, and, no doubt, it would be to the mutual advantage of all concerned if they should become better acquainted each with the other.

THURSDAY AFTERNOON SESSION.

The first paper read was "Direct Driven Generators," which was ordered to take the usual course.

The secretary announced that if there were any gentlemen who desired to make a tour of the car stations and power house cf the Milwaukee Street Railway Company on Friday, cars would be placed at their disposal for that purpose.

Mr. Armstrong, of Camden—I would like the convention to hear a short paper on an important subject. I do not want to take up the time of the meeting, but the subject treated in the paper I think will be interesting to the convention. It has been prepared by the electrician of our company, and is on Magnetic Cutouts.

The privilege was accorded to W. E. Barrington, of Camden, to read the paper, which was ordered filed and printed in the minutes.

The secretary announced that the following companies had become members of the Association:

Chicago, Ill.—Calumet Electric Street Railway Company.

Marinette, Wis.—Marinette Electric Light and Railway Company.

New Orleans, La.—New Orleans Traction Company.

Mr. Lang, as chairman of the Nominating Committee, reported that the committee recommended the following officers:

President, Henry C. Payne, Milwaukee, Wis.

1st Vice-President, W.J. Stephenson, Washington, D. C.

2d Vice-President, James R. Chapman, Grand Rapids, Mich.

3d Vice-President, Lewis Perrins, Jr., Trenton, N. J.

Secretary and Treasurer, W. J. Richardson, Brooklyn, N. Y.

Executive Committee: D. F. Longstreet, Denver, Colo.; Thomas H. McLean, Indianapolis, Ind.; Edward Whittaker, St. Louis, Mo.; W. Y. Seper, Ottawa, Canada; E. S. Goodrich, Hartford, Conn.

Mr. Lang—Mr. Burt, who is president of the Atlanta Consolidated Street Railway Company, appeared before the committee and extended an invitation for the Association to meet in Atlanta next year. He left no doubt in the minds of the committee that there was sufficient hotel accommodation, and that there would be ample provision made for the supply men for their exhibits, even if they had to erect a building for that purpose; that they had the reputation of enterprise to meet any such emergency. The committee feels that if the Association decides to go to that city, it will be pleasant and instructive to all. The committee, therefore, recommends Atlanta, Ga., as the next place of meeting.

A motion was then made that Mr. Rugg, of Pittsburg, cast the ballot of the Association for the gentlemen named as the officers for the ensuing year.

Mr. Hurt was appointed teller. The teller announced a unanimous vote for the persons named, and the chairman declared them to be elected.

Mr. McNamara, of Albany, moved that the recommendation of the committee as to holding the next meeting in the City of Atlanta be adopted. Carried.

Mr. Lusher, of Montreal—At the meeting of the committee this afternoon, in arranging for the next place of meeting, I desired to get in edgeways that there was such a place as Montreal. I was ruled out of order, being a member of the Executive Committee. We should be very much pleased if the Association would hold its meeting in our city the year after next. Of course, if you come to us in Montreal you will be coming to foreigners; but we will treat you in a kindly way. We have good hotels—we all like good hotels and what they bring forth—and we think we have many things of interest in our city, and would like to have you come. Please think this matter over during this year, and at the next meeting we hope you will make up your minds to pay us a visit.

Mr. Longstreet then introduced Mr. Payne to the convention, who said:

Mr. President and gentlemen, I thank you for the high honor conferred upon me by this election. I shall endeavor to maintain so far as lies in my power the high standard heretofore prevailing in this Association. I will not take up the time of the convention in trying to make a speech; and again I thank you.

Mr. Burt—Mr. President and gentlemen of the convention, I wish to assure you that I feel great pleasure in the announcement just made that Atlanta has been selected as the place for your next convention. I can assure you of a hearty welcome; and I earnestly hope that each and every gentleman here will be present with us at that time. We would like you to see what we have been doing in the last twenty-five years. We will give you the best we have in our shop.

The president next introduced Mr. Herbert Claude, of Washington, D. C., who explained the operation of the conduit railway system in that city, and was followed by Mr. M. D. Law, who spoke of the construction of this line, which was done under his superintendence.

At the close of these remarks, Mr. Baumhoff moved the following resolution, which was carried:

Resolved, That the Executive Committee be requested to draft a suitable memorial to the various State legislatures and municipalities, asking them on behalf of the American Street Railway Association to enact laws to prohibit the common practice of children jumping on and off moving cars, and that copies of the same be furnished each member company of this Association.

Mr. Lang moved that the convention return its thanks to the Milwaukee Street Railway Company and the various enterprising men in the city who have extended special invitations for their kind and hospitable treatment while this convention has been in session. The motion was carried and the meeting then adjourned.

The Entertainment.

The delegates were royally treated by the citizens of Milwaukee, and will remember the town with pleasure until able to pay another visit. The hotels are good, the Plankinton being especially entitled to praise for its service and courteous treatment of its many guests.

On Wednesday afternoon the entire delegation was taken in special cars over the electric line to the power house, stopping at the immense engine works of the E. P. Allis Company, where a substantial collation was served. This trip also included a close inspection of the Pabst brewery and its product, both of which are beyond criticism.

On Thursday and Friday the ladies were in the hands of the reception committee, and made several excursions about the city.

Thursday evening the banquet at the Pfister was attended by about 300, and was an enjoyable affair.

The J. G. Brill Company, the Railway Equipment Company and others kept open house in their parlors, and altogether there was no lack of cordial entertainment.

The Boston Specialists.

The Boston delegation started from Boston aboard the special cars Salmon River and Indiana on Saturday at 3 P. M. Their route was via Boston and Albany, New York Central and Michigan Central roads, and they arrived in Chicago on Sunday night. Nearly all the gentlemen were accompanied by their wives, daughters or sweethearts, and the party was a merry one, numbering sixty-one passengers. Following is the register:

W. P. Ferguson, E. P. Shaw, R. S. Brown, H. A. Willis, W. W. Sargent, E. E. Foster, A. F. Breed, John Gorman, W. S. Mendell, E. O. Evans, Chas. Odell, Franklin Woodman, H. B. Rogers, C. E. Barnes, H. H. Damon, E. S. Belding, Samuel Winslow, E. S. Goodrich, E. F. Page, E. L. Fairbanks, H. R. Goodenough, G. M. Hoadly, G. R. Reed, C. D. Morse, C. S. Clarke, E. P. Shaw, Jr., James S. Shaw, C. F. Luther, Geo. F. Morse, W. C. Kuntz, Eben Sumner, Bill Nye, Col. J. H. Cunningham, P. F. Sullivan.

List of Street Railway Delegates and Attendants.

Armstrong, E A, Camden, N. J.
Ahearn, T, Ottawa, Can.
Addison, T, General Electric Co.
Andrew, P, The J. G. Brill Co.

J. G. Brill Co., Philadelphia.
Lewis & Fowler, Brooklyn, N. Y.
Pennsylvania Steel Co., Shelton, Pa.
S. S. Smith, Spokane, Wash.
Harrison & Cary, N. Y.
Peckham Motor Truck and Wheel Co., N. Y.
Mosher Arc Lamp Co., Chicago.
Standard Underground Cable Co., Pittsburg.
National Conduit Co., N. Y.
American Electrical Works, Providence, R. I.
A. Groetzinger & Sons, Allegheny, Pa.
American Electric Heating Co., N. Y.
George Cutter, Chicago.

Convention Notes.

The Mica Insulator Company made a handsome display of their new material, including sections of conduit which they will soon place on the market.

Mr. C. I. Hitts was kept busy shaking hands with his friends of the Novak lamp.

Mr. J. A. Sheriff, of the Mosher Electric Company, had ten Mosher arc lamps running from the trolley circuit just outside the hall, creating a great deal of favorable comment.

The Peckham Truck Exhibit was well patronized, but needed little explanation as all leading roads have them in actual service.

The Westinghouse Electric and Manufacturing Company were conspicuous at the Pfister, and the Westinghouse cars carried most of the delegates between the hotels and convention hall.

The Washburn & Moen Manufacturing Company made a good exhibit of their hard drawn copper wire and other specialties.

Mr. John R. Coffman was active in distributing fac similes of the medal which the Eureka Tempered Copper Company was awarded at the Fair.

The Curtis Electric Company of Jersey City showed one of their motors in operation, mounted on a Brill truck.

The Siemens & Halske Company's 750 H. P. generator coupled direct to a Buckeye engine was a splendid advertisement for both engine and generator.

Major Harry Evans was, as usual, one of the happiest men at the meeting, fully satisfied with the sales of Johnson rails.

The J. G. Brill Company had the most elaborate display of cars, sweepers, etc., including a double decker, in service.

Courses at the Young Men's Institute.

The evening educational classes of the Young Men's Institute, No. 222 Bowery, have a larger enrolment than in any previous year in the history of that institution. Over forty are taking the course in steam engineering, thirty-five in the class in electricity and forty in bookkeeping; altogether three hundred young men, who are working in the daytime, devote their evenings to these studies. Special attention is given to technical subjects and the membership is largely made up of young mechanics.

BOSTON:
W S. KEY, - Room 75, 920 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

The Street Railway Convention.

We present in this issue a report of the Convention of the American Street Railway Association held last week at Milwaukee, and a glance at the list of papers read at these meetings is enough to show the important part which electricity now holds in the street railway industry. It will be noticed that almost every paper read deals with some subject connected with electric railways, and the majority of the papers deal exclusively with electrical subjects. While the prominence of the topic is largely due to the wonderfully rapid introduction of electric railways during the past few years, a still greater reason for the discussion of this subject is that the engineering practice in this branch of street railway work embraces a large field, and includes a number of open questions which remain to be settled. In the cable and horse systems the engineering problems are comparatively simple, and have been pretty closely worked out.

Almost every item entering into the equipment of an electric railway can be profitably studied with a view to reducing the expenses of equipment or increasing the efficiency of the plant. From the boiler plant to the smallest detail of line or car equipment each successive step admits of numerous modifications according to the environments of each special case, and no railway manager can afford to neglect the smallest item which will reduce the car-mile cost of operation on his road.

For these reasons the papers read at each successive convention of the American Street Railway Association have gradually assumed a more technical character, and a number of those read at the present convention deal in a very practical manner with some of the most important subjects which come before the electrical engineer for solution.

......o......

An Unfortunate Precedent Established.

The action of the council of the American Institute of Electrical Engineers in ordering a paper read before another society to be printed in the Transactions of the Institute was severely criticised at the last meeting of that body, and although the decision of the council appears to be final on such questions, the opposition expressed in this case at the general meeting was sufficiently emphatic to show that the introduction of irrelevant matter into the printed Transactions of the Institute for the accommodation of a single member is far from being generally approved.

Although this subject was pretty thoroughly threshed over at the last meeting of the Institute, and is well known to those present at that time, it may not be amiss to briefly present the facts of the case, as those in attendance formed but a small proportion of the total membership.

During the week of the annual meeting of the Institute early last summer an invitation was extended by the New York Electrical Society to attend one of its regular meetings at which the paper under discussion was read, its title being "A Brief Glance at Electricity in Medicine." Dr. W. J. Morton, of this city, was the author, and it must be understood that no objection can be raised as to the merits of the paper, which bears evidence of very thorough technical knowledge and research in this branch of medicine.

It appears that this paper had been prepared at the request of a member of the council of the Institute to be read before that body, and a promise had been given by that member to have the article printed in the Transactions, though with what authority does not appear. The paper, however, was read at a regular meeting of another society, as every printed announcement of it shows, and for that reason has no connection with the proceedings of the American Institute of Electrical Engineers, and has no right to appear in its Transactions.

In order to fulfil the unauthorized promise of one of its members, the council of the Institute ordered this same paper to be read by title at a regular meeting of the Institute nearly six months after its delivery before another society, and to be printed in the Transactions.

This arbitrary proceeding on the part of the council can only be explained by its desire to relieve one of its members from the embarrassment in which his unauthorized assumption had placed him; and it is to be regretted that sufficient influence was brought to bear in his behalf so that, in spite of all precedent, as well as propriety, the Institute is obliged to appropriate the paper of another society and bear the expense of printing it in its Transactions.

It is certainly an unhealthy condition in any organization when a single member or a small clique is able to commit it to such an unprecedented action, and it is to be hoped that the dissatisfaction expressed in this instance will deter the council from committing any further irregularities during the remainder of its term.

The Institute can justly feel proud of its printed Transactions, and it should be the aim of every member to maintain them at the highest standard, but according to the precedent just established there is nothing to prevent the publication in them of any other society's papers at the pleasure of some member who possesses the necessary influence.

......o......

A Common Sense View.

It is certainly refreshing to find a New York newspaper sufficiently unprejudiced on the subject of trolley railways to apply an ordinary amount of common sense to the discussion of rapid transit, and in this respect the New York *Independent* is to be congratulated.

In an article recently published in that paper, headed "Rapid Transit in Cities," the writer has omitted the usual death-dealing, murderous and deadly epithets which are generally applied to the trolley, and has substituted a commendable amount of logic in place of the usual invective.

The conclusions drawn in the article are of considerable interest and should carry weight, as the writer proves his judgment to be unbiased in either direction by finding the trolley to be neither an unmixed blessing nor an unmitigated curse.

Speaking of the experience of Brooklyn, it states that within a short time most of the surface roads of that city have changed from horse power to trolley. The promoters of the change calculated on an increase of 25 per cent. in the number of passengers, but the trolley cars have actually carried more than double the number of two years ago. It is also beyond question that the speed with which the trolley cars now move from the business centre of Brooklyn to the outlying sections of the city, together with the better cars used, is favored by the traveling public, as shown by the great increase in the number of passengers carried.

But the new system brings in its own problems, and nowhere more seriously than in Brooklyn. Fulton street, the main thoroughfare, winds through the city, taking its course from the old cowpaths. Out from it radiate the other avenues, and the consequence is that the main street in its lower part is choked with traffic. Since the advent of the trolley things have become worse, until it is now dangerous even for an adult to cross the street, while children are killed nearly every day. We are thus brought squarely to consider these two opposing conditions, and whether we like the trolley or not it seems quite reasonable to assume that the surface cars in our cities will generally move faster than did the old horse cars. The great gain to the majority of the people from more rapid transit is certain in the end to overcome the disadvantage to the few. Many have a great dislike to the trolley, and its poles are indeed often most unsightly; but the *real complaint* is against the increased rapidity. Yet there seems no hope of returning to slow speed, even if some other form of propulsion less ugly than through the overhead wire be discovered.

This, we believe, constitutes the true explanation of the opposition with which the introduction of trolley roads is often met. The kind of motive power adopted makes very little difference to the public, and accidents due to the electric currents of railways are at most very rare, and with the best construction may be entirely avoided. The real opposition to the trolley lies in the increased speed of these cars over the old horse cars, and on the other hand this greater speed is just the condition demanded by the traveling public.

As the trolley system has been the first to comply with the demand for higher speed it has had to bear the onus which this condition imposed, but when the prejudice on this subject gives way to reason, it will be admitted that this motive power has been held responsible for what the speed, which the public demands, is alone to blame.

……

The electrical trade is well represented in the political campaign just opening. Mr. James A. Roberts, of Buffalo, being a nominee on the State ticket for Comptroller, and Mr. Charles A. Schieren, of Brooklyn, a nominee for Mayor of that city. Both of these gentlemen have the best wishes of their electrical friends, and are sure to carry the solid electrical vote.

A Doubtful Retrenchment.

To the Editor of Electricity.

Since my last letter, September 15th, I am informed that Mr. Sunny has inaugurated a nondescript departure in the management of the Chicago office of the General Electric Company, which as a "dust thrower" may be a temporary success, but as a "dividend earner" is as dismal a failure as his previous schemes. His first move in the game has been the consolidation of the seven divisions of his sales department (referred to in my former letter) into five departments—a wonderful stroke of economy!—retaining his previous seven managers by hiding two of them as assistant managers, and still using the pruning knife among his poorly paid employees. He thus persists in carrying out his deceptive policy of retrenchment and reform under a new garb, concealing, as he vainly imagines, his true motives, as the ostrich thinks he hides his body in concealing only his head. Every one familiar with the present business of the General Electric Company in the Western district knows full well that there is no department which requires the services of an assistant manager; but his particular cronies must be cared for—perhaps it is necessary to "close their mouths" in this way, that the true inwardness of his business methods may be for a time concealed from the blinded stockholders. His second move in the game is in a reduction of five per cent. upon the monthly salaries of employees receiving $100 and under, and a reduction of fifteen per cent. on monthly salaries of over $100. We have not heard whether Mr. Sunny has made a proportionate reduction in his own salary and that of his department managers—judging from his previous policy of beginning at the wrong end, hardly yet, if ever. A great many people in this city like yourself have questioned whether the withdrawal of the Fort Wayne Company from the Electric Trust is bona fide. From appearances its connection with the Trust was not bona fide. The policy of the Fort Wayne Company has been entirely independent of the Trust and dictated by Mr. McDonald, although ostensibly given out as if a part of it. The Thomson-Houston, Edison, Brush and Excelsior Companies have, however, been under the control of the chief officials of the Trust, the interests of the Trust being used to further those of the Fort Wayne Company, where possible, to the exclusion of all those other companies composing it; especially does this seem to be the case with the Chicago office. We have learned from those who have been in a position to know, that in the sale of plants where the agents of the Thomson-Houston and Fort Wayne Companies were in competition, those of the Thomson-Houston Company were not allowed to cut figures (although there was plenty of margin to do so) to meet those of the Fort Wayne Company, but ordered to assist the agents of the Fort Wayne Company in securing the contract, while when in competition with the apparatus of the Edison, Brush and Excelsior Companies (members of the Trust), liberty was given to meet the figures of these companies. Some have considered this action of the "powers that be" in the Chicago office to signify that Mr. Sunny, as well as Mr. Coffin, are so interested with Mr. McDonald in the Fort Wayne Company that they receive greater benefits to themselves from the sale of the apparatus of that company, not having the same interests in the apparatus of the other companies composing the Trust. I must say that all appearances lead to such a conclusion, and I would not in the least be surprised to hear, upon the retirement of Mr. Coffin from the General Electric Company, of the formation of a company by Messrs. McDonald, Coffin and Sunny, under the title of the Western General Electric Company, as rumor has it, if they have not already done so.

If by these letters I can, through Electricity, open the eyes of the Eastern stockholders to the strange management of this district as one of the causes for the depreciation of their stock, and thus remedy the evil, if possible, I will have fulfilled the purposes I have in view.

Stockholder.

Chicago, Oct. 12, 1893.

Mr. R. T. McDonald Arrested.

A Charge of Forgery Made.

Warrants for the arrest of Mr. R.T. McDonald, of the Fort Wayne Electric Company, together with several other directors of the Madison Square Bank of New York, were issued on Monday on the information of the receivers, who charge gross irregularities in the management of the bank's business.

It is alleged that Mr. McDonald subscribed for $100,000 of the stock, for which he was to pay $150,000 in cash, and it was sworn that he had so paid. He became a director on the strength of that subscription and supposed payment. Then, it appears, he borrowed the entire money from the bank with which to make the payment, and the directors passed a loan, some of them at least knowing the purpose for which it was made. McDonald and Uhlmann, another of the directors, practically ran the bank for over a week prior to its failure, and they must have known of its rotten condition all this time. A few days before the failure McDonald, who, with Uhlmann, was managing the bank, under a written authority from Blaut, whom they sent away, directed the cashier to take his notes of $150,000 and indorse on the back of them that they were not negotiable, thereby changing the entire character of the security.

Legal Notes.

In a suit brought in the Mercer County (N. J.) Court for damages for injuries received from being struck by an electric street car, Judge Abbett, before whom the case was argued, held that it was the duty of the plaintiff (Mrs. Cecilia Connelly) to look the instant before she stepped on the track, and in failing to do this she was guilty of contributory negligence and could not recover. An exception was allowed and the case will be taken to the Supreme Court.

On the recommendation of Master in Chancery Noyes, Judge Ewing has appointed C. S. Burton receiver for the Cicero Light, Heat and Power Company. The company was organized in 1891 and owns valuable plants, franchises and contracts, and supplies Cicero, Oak Park and other suburban towns near Chicago with light.

Judgment for $12,419 has been entered in New York against the Brush-Swan Electric Light Company of New England, of which Colonel William L. Strong has been president, in favor of William R. Montgomery, for legal services performed in an equity suit in the United States Circuit Court in which the above company was complainant and the Brush Electric Company defendant. The legal work was performed by Evarts, Choate & Beaman and William G. Wilson, who assigned the claim to Mr. Montgomery.

In the United States Circuit Court, New York, on Thursday last, Judge Lacombe appointed Henry C. Adams ancillary receiver for the Newtown Electric Company of Newtown, Long Island, to take charge of the company's affairs in the home district. Receivers for the firm were appointed by Chancellor McGill of New Jersey on October 16.

Some Measurements of the Temperature Variation in the Electrical Resistance of a Sample of Copper.—II.

BY A. E. KENNELLY AND REGINALD A. FESSENDEN.*

DESCRIPTION OF TESTS.

Within the cylindrical glass tube of an air thermometer was enclosed about 240 cms. of fine copper wire. Short platinum wires sealed into the glass bulb brought this copper wire into communication with apparatus for measuring its resistance. The bulb rested in an oil bath heated electrically, and the height of a mercury column required to balance the pressure of the internal air was measured by cathetometer at the moment that the resistance of the copper wire was noted. The bulb was thus operated as an air-thermometer at constant volume, and corrections were applied to the expansion of the glass walls of the bulb, and for the variation of barometric pressure during the period of observations, also electrically for the resistance of the leads up to and including the platinum seals.

A vertical section of the thermometer bulb and its accessories is shown to one-third true scale in Fig. 1. The capacity of the chamber was approximately 75 c. c. Three separate platinum wires were sealed in at D, and welded with three exterior copper wires, E, F and G, forming the leads to the apparatus. The central was also welded within the bulb to a copper wire, and the seal supported this wire axially along the bulb to its termination at H.

This copper wire DH was entirely covered by a glass tube, closely threaded on which were beads or short cylinders cut from glass tubing. The beads served as sleeves or washers to clamp between them at their junctions circular disks of mica, with a hole in the centre. Two circles of holes were drilled concentrically around this disk, each circle having fifteen holes. A plan view of a mica disk is shown in Fig. 2 to full scale.

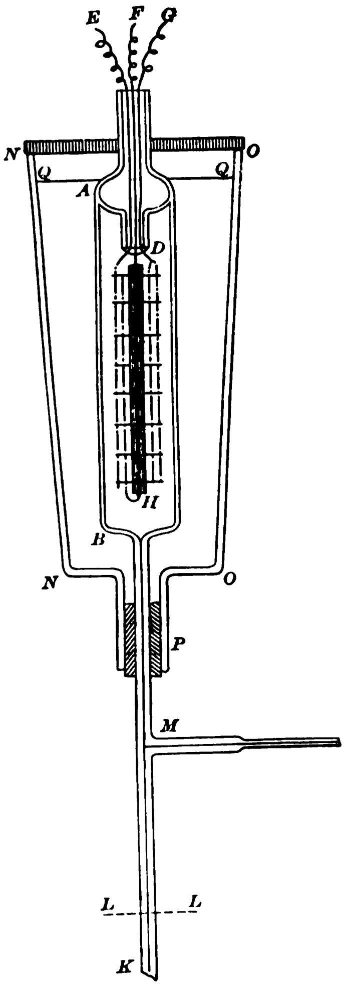

Fig. 1.

The copper wire tested was of good commercial quality and double silk covered. The silken covering was dissolved off with hot caustic soda, diluted so as not to oxidize the wire, and the bare wire threaded up and down through the mica disk and parallel to the axis of the bulb, first filling up the inner cylinder of holes and then the outer. The inside end was soldered to platinum wire No. 1, connected with the lead E, the final exterior, and soldered to platinum wire No. 2, from lead G, and the junction or midway point connecting the inner and outer cylinders was connected to the copper wire at H, which communicated with lead F. By this means two separate loops of wire of nearly equal length were provided within the bulb, arranged in two cylinders, one within the other. The object of this arrangement was to furnish a check by duplicate, upon the observed resistance of the tested wire, and so to ascertain what difference in temperature, if any, existed between the air at radius 0.5 cm. and the air at radius 0.8 from the axis of the bulb, the source of heat being entirely external. Had the mean temperature of the inner and outer cylinders differed at any time in virtue of gradient of temperature within the bulb, by one-tenth of one degree centigrade, it would have been within the range of observation, and had it amounted to one-fifth of a degree it could not have escaped detection. No appreciable difference was at any time discovered, the increase of resistance in the two cylinders being always proportionally coincident, so that finally the two loops were combined into one for facility in observing, and only divided for an occasional check. The diffusion and convection of the air within the bulb must have been sufficiently rapid to practically equalize the temperature within the air space. The course of the wire within the bulb is indicated by the dotted lines in Fig. 1.

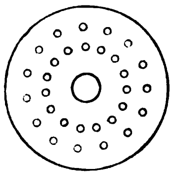

Fig. 2.

The bulb communicated with the mercury through a glass tube DK, round which a hair, secured 15.2 cms. below the bulb at L L, formed the fiducial mark.

The bulb was held vertically upon the axis of a glass percolator N N O O, the lower tube passing through a rubber stopper at P. The space between the bulb and walls of the percolator was filled with boiled linseed oil up to the level Q Q, and a cylindrical grid of platinoid wire, not shown in the figure, was immersed in the oil. A steady current of from two to three amperes through this platinoid wire of 16 ohms resistance served to raise the temperature of the oil and immersed bulb at a convenient rate. A disk of asbestos cloth, N O, rested as a cover upon the percolator, and more of the same material was wrapped around the exterior surface N N O O, in order to impede the escape of heat from the chamber.

The resistance of each cylindrical loop of wire within the bulb was about 10 ohms at the normal or initial temperature, in the vicinity of 20 C., making twenty ohms in all, and at the highest temperature reached in the measurements these resistances doubled, so that the total range of observed change in resistance amounted to 10 ohms in each loop or 20 when the loops were in series.

In the first trial, the resistances were measured by Wheatstone's bridge. This method was found to be unsatisfactory both in respect to swiftness and precision.

Later, two differential galvanometers were employed. One balanced the two loops within the bulb against each other to detect variations of temperature within the bulb, and the other compared the resistance of both loops in series against a fixed standard in platinoid wire (30 ohms).

Finally, the first galvanometer fell into disuse, since no variation could be detected between the resistances of the two loops, and measurements were confined to the second differential galvanometer, with one Wheatstone bridge reading as a check at the outset and another at the culminating temperature of the series.

The differential galvanometer method is very convenient for such measurement. It enables the variations of the tested resistance to be constantly watched and balance can be quickly readjusted with a dead-beat instrument by rheostat thrown into the circuit of preponderating influence.

The main circuit consisted of the bulb with its two loops in series, a standard resistance of 30 ohms in platinoid, and an additional resistance of 50 ohms in a rheostat. A single Edison-Lalande cell delivered a steady current of from 6 to 7 milliamperes through this circuit. The two coils of the differential galvanometer had about 2,700 ohms each; one was connected to the terminals of the standard 30 ohms, and the other to the terminals of the bulb. A change of resistance in circuit of either coil amounting to 1 ohm could be plainly observed on the scale.

The first four series of observations were rejected. When computed and plotted, with ordinates of resistance to abscissas of temperature, they showed curves bending slightly upwards, after the manner of Matthiessen's, but the descending curve was distinctly below the ascending branch, so that the diagram appeared to form a loop as though the wire had a lower resistance for a given temperature when cooling than when heating. The cause of this error is not known, but may have been due to fluid friction of the mercury in the bulb tube.

The sixth series appeared to be most reliable. Its graph is practically a straight line up to the maximum temperature of 255 C. with no appreciable deviation between the ascending and descending branches, the latter being carried in this instance no lower than 207° C.

(*Concluded.*)

American Institute of Electrical Engineers.

At the regular monthly meeting of council, held October 18, the following associate members were elected: Merton H. Bentley, Richard Fleming, J. A. McCrossan, Loyall Allen Osborne, Russell Robb, Henry H. Sykes.

At the 80th meeting of the Institute in the evening, the paper announced by Dr. Frederick Bedell on "Hedgehog Transformer and Condensers," and that of Ralph W. Pope on "Monthly Meetings of the Institute," were read by the authors.

The following resolutions were subsequently passed:

Whereas, Requests and suggestions have been received from members in various parts of the country looking to the holding of local meetings for the reading and discussion of papers, and

Whereas, It is the sense of this meeting that any measures proposed with the view of increasing the usefulness of the Institute to its distant members should have earnest consideration and careful action; it is hereby

Resolved, That the president be requested to appoint from the council a committee to consider the subject of local meetings; such committee to be supplied with copies of all correspondence and papers on the subject in the files of the secretary and that the council report as early as possible to a monthly meeting of the Institute: first, upon the expediency of local meetings, and second, if they deem such meetings expedient, to recommend a suitable plan for the organization of local meetings and for their proper relation to the general body.

---

* Read at the International Electrical Congress, Chicago.

Report of Committee on "Direct-Driven Generators."*

TO THE AMERICAN STREET RAILWAY ASSOCIATION.

Gentlemen : Back in the early eighties the different manufacturers in Europe, including Brush, Siemens & Halske and others, commenced the building of direct-driven generators of small capacities connected to different types of engines, operating at a high rotative speed. Among these were a large number of Brush machines connected to Westinghouse engines. About the first apparatus for use in central power stations were those designed and built by Mr. Edison for the old Pearl Street Station in New York City. These machines were about 300 horse power capacity, directly connected to an Armington-Sims automatic, single cylinder engine, operating at about 250 revolutions. This apparatus is still in use at the present day, except a few of them which were destroyed in a fire in the station several years ago. One of these units is shown in the exhibit of the General Electric Company at the World's Fair. There is also a large power station operating in Milan, Italy, with the same type of apparatus. Although it is now nearly ten years since these particular units were built, it is only within the last two years that we have commenced their their introduction to any general extent on large power station work. Although these units operated in general in a satisfactory manner, the type of generator and engine was not perfected generally to give the best of service, and therefore electric manufacturers abandoned their development after these first ones and returned to belt-driven generators, and they continued to be the standard type of power station generators until two years ago.

In Europe, though, we have a different history of the matter. The development of their electric apparatus has been slower, and they have therefore had more time to work up special designs and perfect different types of generators. The general commercial requirements were not so rushing, and when American manufacturers commenced to develop to a large extent direct-driven generators, they found their co workers in this line in Europe so far ahead of them in that they had several years ago a number of large stations in Berlin, Paris, London and other parts of Europe operating with units up to a thousand horse power, directly connected to different types of engines, principally vertical ones. The writer remembers in 1887 and 1888, when he was connected with one of the electric manufacturing companies, the difficulty he had to get the shops to build the first small direct-connected generator for naval service. This really commenced the development of this type of apparatus with American manufacturers, and the old Edison, Thomson-Houston and Westinghouse Companies commenced building them in small units. All of the foregoing generators, although for different types of central station and power work, were not any of them used on electric railroad work. Commencing in 1890 the Thomson-Houston, Edison, Westinghouse, and later the Siemens-Halske Company of America, commenced designing and building railway generators for direct connected work, and during the past year there has been quite a number of new stations operated and building which are equipped entirely with direct connected generators, running in size all the way from 100 K. W. to 1,500 K. W.

The type of generator being built and furnished to-day for direct connected work is far superior in every respect—almost beyond the question of comparison—to the early and antiquated small generators which many of our friends are using and struggling along with to the tune of the popping of the safety fuses and circuit breakers, the whirl of the revolving grease-besmeared belts, and the squeak of the friction clutch pulley. The direct-driven generators built by the different manufacturers in a large measure are of the same general construction so far as general details go, differing in minor points only.

TYPE OF ENGINE TO USE.

The type of engine to use in connection with the operation of direct driven generators is one of the serious factors to consider in this connection.

There are many points to be considered of economy, reliability, continuous service, good regulation, ability to stand the direct and severe shocks due to overloading generators, short circuits, economy in floor space, etc.

On the question of whether vertical or horizontal is better adapted, common sense seems to indicate that as we are laying out a compact plant in every respect, a vertical engine is best adapted for this work. The question of regulation is a very serious one. The engine is undoubtedly called upon to stand a test which no belted machine has had to do on account of being directly connected to the generator, and some one of the different types of shaft governors in use on some of the standard machines seems to be best adapted thereto, and will govern within a range for this work of say two or three per cent.

On the question of economy so-called high speed engines are in a measure out of date on this kind of work, as generators are reaching a size beyond the capacity of our old friend, the single valve automatic engine. This engine seems to have reached its limit in economy at about 200 to 300 horse power, that is, where controlled by a single valve. We are confined, then, to one or two types of engine. The old standard of general commercial practice, the Corliss engine, which, on account of our large experience with it, has been called upon more largely for service on this kind of work than any other, in general is meeting these requirements in most respects. There seems, though, to be some question of reasonable doubt as to whether it will regulate sufficiently close to meet the more exacting requirements of this class of work where called upon to control very wide and sudden changes of load. On the question of economy they have shown in the past the highest economy obtainable, but that has been more especially on steady loads near their rated capacity. With loads which fluctuate as railroad work does, they cannot reach nearly their guaranteed economy. We also have the disadvantage of the controlling valve when cutting off over half stroke. In Europe, where their practice on direct connected work has extended over a much longer period than ours, they are using largely various modifications of the vertical marine type of engine, controlled by different types of governors. An engine of this class, well and substantially built, with double valves on the steam and exhaust, and controlled by shaft governor controlling the valve up to the three-quarters cut-off, would seem to combine many points of superiority of an engine on this class of work, and give service in reliability, economy and durability superior to any other type obtainable. Manufacturers and designers in this country are now rapidly developing this type of engine, which is being built by such manufacturers as the Lake Erie Engineering Works, Dickson Manufacturing Company, McIntosh & Seymour, Porter-Allen and others.

RELATIVE ADVANTAGES, COST AND ECONOMY.

The electric railroad manager says: This matter is very interesting, but where do I come out on the cost and as to economy? I will try to give him a few practical points in this regard. In general, the generators are being sold to-day for about 20 per cent. above the cost of belt driven machines of the same capacity. As we reach the larger units which are now being built, this difference will be considerably reduced. Allowing, though, for this difference in cost of the generator, we find, after carefully reviewing several cases in the writer's experience and that of others, that the cost of the power station complete, exclusive of real estate, but including the same electric plant and building, is not more on a direct driven plant than the older type of belted apparatus. This should settle the question beyond doubt, especially where new stations are being built. I feel that I cannot impress upon you too strongly the fact that many of the railroads are going to find it to their advantage to scrap and sell at the best advantage they can their present apparatus, and build a new and modern station. The economy gain will be a large one in every respect; more reliable service; satisfaction to the public; reliance in the operation of their car service, which they have never been able to realize with their old type of small belted generators; and a reduction in station force, which will be appreciated by every dividend loving stockholder. I have tried to obtain the best and most reliable data on this question of relative economy. Most of the railroad stations of the direct connected class have only been in operation a short time. We have a number of central power stations though, where questions of relative economy show up on a similar basis, where we have been able to obtain more reliable data. When we look around and see the present stations operating with all types of engines, connected to various sizes of generators and giving a result in economy on the horse power output of all the way from four pounds on the most reliable to eight and nine pounds of coal on the medium ones, we see that there is indeed room for improvement. We have beyond question doubled this economy through a better, larger and more economical type of engines, operated under better and more favorable conditions; also more economical, direct connected generators, saving in loss of belting, shafting, friction, etc.; also of a combined, direct and positive saving, bearing all the way from 10 per cent. to 50 per cent. These figures are not theory, but are results obtained from actual practice, as is shown by data in the hands of the writer. As to whether it is going to pay to overhaul your plant as herein proposed, I will give one specific instance of the careful review of the case of a power plant of about 5,000 horse power. The company has become convinced that they could build a new power plant and scrap their present apparatus, increase their fixed charges thereby $15,000 a year, and still have a net gain over their increased charges of $25,000 per annum, and in addition to this a far more reliable and better operating plant and increased capacity. I could continue enumerating examples of this kind, but believe if you give the matter careful consideration, you will be fully convinced on the subject yourself.

SUMMARY.

I feel that if any railroad man, either from a practical or business standpoint, after carefully considering the matter, looks around and sees the relative advantages of these plants, he will beyond question become an advocate of direct connection, and his only wonder will be that he could be satisfied with any other type. When we realize that electric railway work has all been developed from a practical commercial standpoint in the past five or six years, it is almost beyond comprehension to realize the progress that has been made in the development of all the different types of apparatus, and more especially in the generator, for if we look back at the 30 or 50

---

* Abstract.

K.W. machine which was used in the early stages, and at the 80 K. W. which was the standard about three years ago, and then consider the 1,000 and 1,500 K. W. generators, we can but feel that we are in an age of rare development and progress almost beyond our comprehension. I feel that we have now reached what may be termed a point of standard commercial perfection on generators for power service of all descriptions, and that the next ten years will see very little change other than the perfection of minor details thereon, and instead of having a station operating from twenty to forty varying types and kinds of small generators, we will have a compact and modern plant of a few large units.

Trusting this report will lead to further consideration of the matter by all interested, it is

Respectfully submitted.

C. J. FIELD, *Committee.*

Current Items.

The Electro-Pneumatic Automatic Block System now being introduced on the Pennsylvania Railroad is working with perfect satisfaction, and is said to be a great success. The principle of the system is that signals are thrown to the danger position automatically by a train entering the block which the signal controls, and are returned automatically to the position, indicating that the track is clear as soon as the train leaves the block. When there is any failure in the operation of the automatic apparatus, the home signal inevitably assumes, through the action of gravity, the danger position. The new system is more expensive than the old one, the cost of installation being greater, although the cost of maintenance is less. A good deal of the danger through human fallibility is eliminated. A broken rail, which a towerman would never know anything about, is instantly reported by the signal, as is any other obstruction or interruption.

A plan for the distribution of electric power over a good portion of England is proposed by A. B. H. Thwaite. His idea is to burn the fuel at the mines, where it costs but little, and then transmit the power resulting from the combustion of the coal and gas by high pressure alternating currents of electricity. He proposes to use gas engines of not more than 500 horse power to generate the electricity. From one station he would supply the centres of industry of Lancashire and the area adjoining the ship canal; from a second those of Yorkshire; from a third those of Midlands and London.

A writer in the Pittsburg *Dispatch* describes a device which has been brought out to control the electric currents employed for lighting purposes. The arrangement is somewhat complicated, but its working is as follows: When the specified number of lamps have been lighted, they require an amount of current just sufficient to keep the circuit closed. But if an additional lamp be lighted, the excess of current passing through the mechanism of the tell-tale device magnetizes an electro-magnet strongly enough to attract an armature. The movement of this armature causes a wheel to revolve, and the revolution of the wheel breaks the circuit momentarily and turns the additional lamp off. This restores the normal supply of current, and the proper number of lamps continue to burn steadily. The clock motor employed in this apparatus runs a fortnight, and is constructed to give 2,700 interruptions, which number is deemed sufficient for practical purposes.

The Chicago Telephone Company now makes claim to having the most complete, as well as the busiest, telephone exchange in the world. Chicago has 10,400 telephones, operated in 11 exchanges. The number of "talks" really represents the business of the exchange, and they number over 145,000 a day. To accommodate this vast business the telephone company has put down 48 miles of underground conduit, containing 18,000 miles of wire.

Boston Notes.

To mitigate somewhat the privations of the laid-off employees connected with their Lynn factories, the management of the General Electric Company has determined upon a system of alternation by which those men who were discharged some time ago owing to the financial depression will be given employment a portion of the time, while those now working steadily will have to take even chances with the others. This is an arrangement which we think cannot fail to be appreciated all round by virtue of the old adage, "Half a loaf is better than no bread."

The town authorities of Medford, Mass , have granted authority to the West End Railroad Company of Boston to construct an electric railway through that town, connecting with Malden and Boston. A certain section of the road is to be in operation by January 1 next, and another year is granted for the company to complete the entire work. The West End Railroad Company accepts the conditions.

The Massachusetts State Board of Railroad Commissioners have been busy this week attending to various electric railway enterprises. They have granted authority to the Rockland and Abington Street Railway Company to issue its $60,000 additional stock at par; they have been to Fitchburg to try and settle a dispute about a grade crossing over the Old Colony road, and been over the territory in Cambridge which is in such hot dispute between the residents and West End Railroad Company. This latter dispute is becoming quite famous.

Professor Elihu Thomson is to deliver a lecture in Odd Fellows Hall, Lynn, November 16, on "High Frequency Alternating Currents," which will be illustrated by showing Professor Thomson's personal exhibition now at the World's Fair, Chicago. This lecture is sure to attract great attention, as do all addresses by the earnest and genial professor.

Lasell Seminary, Newton, Mass., is to be lighted by electricity from a private plant which Professor C. C. Bragdon, one of the faculty, is about to erect for himself.

There is a growing feeling in Newton, Mass., in favor of the City Government owning the electric light and gas plants. At present both gas and electric lighting are done by the local company, and while municipal ownership is considered desirable the Street Lighting Committee in a report that is being prepared does not favor the purchasing of the existing plants, but the establishment of an entirely new one.

The appointment of a new president of the West End Railroad Company, Boston, to succeed Mr. W. M. Whitney, retired, will not take place until the annual meeting next month. Meantime the affairs of the company are being well taken care of by the directors, who however are not just now extending the electric system.

The W. S. Hill Electric Company is to be congratulated on the unwonted prosperity it is enjoying 'mid all the depression and stagnation that abound, and it is a pleasure to us to be able to record the fact that this company is actually running its factory both day and night to keep pace with its orders. The company has recently secured a contract from the Philadelphia Traction Company which among the items calls for a number of switches aggregating 35,000 amperes capacity. One of these switches will be for 4,000 amperes, the largest ever made. Another contract includes a handsome marble switchboard 27 feet long, with several a trifle smaller. The goods, devices and apparatus manufactured by this company enjoy so high a reputation that they are coming into demand everywhere.

Mr. J. E. Talbot, for the past six years one of the managers of the Fort Wayne Electric Company's factory, Fort Wayne, Ind., and who is known and highly respected throughout all the East as well, has taken up his residence in Boston, and will practise as consulting electrical engineer and expert in patent causes. He will also edit *Elektron*, a monthly magazine devoted to electricity and its allied interests in their scientific and practical aspects. This magazine will be something entirely new in the literature or bibliography of electrical art and science: a high class monthly in which will appear articles of fine literary and scientific merit contributed by many of the first writers and most eminent specialists of the age. Mr. Talbot is a technical writer himself of considerable repute, has had journalistic experience, and with his scientific attainments, wide and varied practical experience cannot fail to win success. A long personal and professional acquaintance prompts us to speak only in the highest terms of him and to hope for a full measure of prosperity in the duties he has undertaken.

Mr. Winthrop Coffin, of the General Electric Company, and Mr. W. T. Rossell, of the Electrical Corporation, have been elected directors of the Concord Land and Water Power Company.

Messrs. Phillips, Leverett Saltonstall and Chas. C. Pierce have been appointed agents for the General Electric Company's railway department for New England.

General News.

What is Going on in the Electrical World.

Worcester, Mass.—The committee on sewers has voted to put in an electric light plant at the Quinsigamond Purification Works,

Richmond, Va.—Some of the papers are urging the council to put in an electric lighting plant to be owned and operated by the city.

Hillsdale, Mich.—The Jonesville Electric Light and Power Company have submitted a proposition to the city council for lighting the city.

Denver, Col.—A new electric company, the Economic, has entered the field against the Consolidated Company, and put in bids for lighting the city.

Savannah, Ga.—The Electric Railway Company has ordered a cut of 10 per cent. in the wages of all of its employees, to go into effect November 1.

White Fish Bay, Wis.—At a mass-meeting held here a few evenings ago, two-thirds of the people voted in favor of bonding the village to build an electric railway.

Canton, Ohio.—The Canton-Massillon Electric Railway Company is rebuilding its car-house and has ordered new cars, etc., to restore the plant destroyed by the recent fire.

Fond du Lac, Wis.—In spite of the business depression the electric street car company has gone on with work on its line and last week was able to begin carrying passengers on it.

Norristown, Pa.—There is talk here of changing the steam road to Lansdale into an electric road. The distance between Norristown and Lansdale is about ten and one-third miles.

Monroe, Mich.—The Toledo, Monroe and Detroit Electric Railway Company, having secured the right of way from Toledo to this city, are now after a franchise to operate their road on several streets here.

Troy, N. Y.—The E. G. Bernard Company has been awarded the contract for putting in the new power and lighting plant at the Watervliet Arsenal. The light plant will have a capacity of 5,000 or 6,000 lights.

Leavenworth, Kan.—It is reported here that the New York capitalists who are converting the horse car system of Atchison into an electric line are likely to apply for a franchise for an electric system in Leavenworth.

Montreal, Can.—The Ball Electric Light Company (limited) of Canada have sold to the Canadian General Electric Company (limited) their entire electric manufacturing business, including patterns and goodwill.

New York.—The Railroad Committee of the Board of Aldermen, after investigating the matter, have reported that the Second Avenue Railroad Company have the right to use the storage battery system on their road.

Sterling, Kan.—The Sterling electric light plant was destroyed by fire on the 14th inst., leaving the city in total darkness. The plant was the property of J. H. Ricksecker, of Kansas City. The loss is about $6,000.

Camden, N. J.—The work on the extension of the Camden, Gloucester and Woodbury Electric Railroad from Fancy Hill to North Woodbury is rapidly progressing, and cars will probably be running over the extension in the course of two weeks.

Erie, Pa.—Mayor Scott has affixed his official signature to the Edinboro and Erie railroad ordinance, which now becomes a law. The company is required to begin the work of construction within sixty days, and complete the road inside of a year.

Hartford, Conn.—At a public session of the joint convention of the common council held a few evenings ago, there was a preponderance of argument in favor of the use of the trolley in this city, but as there was not a quorum present there was no action taken.

Hamilton, Ohio.—The proposition to issue $50,000 in bonds for the erection of an electric light plant will be submitted to a vote of the citizens on November 7. If carried the city will be released from the contract entered into by council with the Hamilton Brush Electric Light Company.

Winona, Minn.—The Winona General Electric Company have remodelled their plant, and have placed their lighting and street railway interests under one roof. The Winona Company is a branch of the Northwest General Electric Company, and most of the stock is owned by the latter.

Allentown, Pa.—The Pennsylvania Telephone Company suffered a loss of $10,000 by the fire which occurred here on the night of the 13th inst. The fire broke out in the Telephone Exchange, and was caused, it is said, by the crossing of telegraph and electric light wires. The total loss was $200,000.

Manchester, Conn.—In the reorganization of the Mather Electric Company at Hartford last week, M. S. Chapman was elected president in place of B. A. Simmons, resigned, Charles B. Whiting vice-president, and C. T. Welles secretary and treasurer. The company has made a satisfactory basis of settlement with all its creditors and is now prepared to execute orders.

Martinsburg, Md.—The council has declared the franchise granted by it to the Martinsburg Electric Railway Company forfeited, and has served notice on the company to run no more cars or perform any work on the track or wires connected therewith. John B. Wilson, the president of the road, announces his intention of suspending operations until next spring election and then appeal to the people of the town for a settlement of the question by their ballots.

Chicago.—J. J. Brice, U. S. N., inspector Ninth Light-house District, reports that the electric buoys at Lake Michigan, installed by the Bishop Gutta Percha Company, and extending from the foot of Van Buren street to the World's Fair grounds have been running as regular as clockwork since their acceptance by the Government. None of them have failed for a single night. During the heavy storm of a few weeks ago the waves ran high, yet none of the lights went out.

Baltimore.—"The burning of the Brush Electric Light Works," says the Baltimore *Herald*, "is one of the most serious losses which Baltimore has sustained for some time. Not only has the electric company's entire plant been ruined, but the electric lighting facilities of the city are very much crippled. One or two lines of street railway also are hampered by the fire, and some time will elapse before the various facilities for travel and street lighting will be restored."

Detroit, Mich.—The city council has adopted an ordinance to the effect that any person or corporation carrying on a manufacturing business in the city of Detroit, and having surplus power applicable to the purpose, may apply to and receive a permit from the public lighting commission to lay conduits, erect poles and place thereon or therein wires or other conductors for the purpose of furnishing electric lighting to any person or persons desiring the same within the district to be designated in the application made for such permit.

Wilmington Del. — The Wilmington and Chester Electric Railway Company was organized here a few days ago. The following officers were elected to serve until the annual meeting next January: President, James C. McComb; secretary, E. T. Cooper, Dover; treasurer, J. Clayton Erb, Philadelphia; directors, William G. Hill, Philadelphia; S. F. Houseman, Philadelphia; John B. Robinson, Media; J. Clayton Erb, Philadelphia; Richard R. Kenney, Dover; Garret J. Hart, Wilmington; James C. McComb, Claymont, and Peter J. Hughes, Philadelphia. Work on the new road will be begun next March.

Newark, N. J.—A correspondent of the *Sunday Call* suggests the holding of an electrical exhibition in Newark some time in the coming winter. He says the electrical interests of the city are extensive enough to warrant such an exhibition, and has no doubt of its success. He gives the following list of manufacturers in the city and suburbs who would furnish exhibits: The Weston Electric Instrument Company, the Westinghouse Electric Company, the Edison Phonograph Works, Orange, N. J., the Edison Lamp Works, Harrison, N. J.; the Crocker-Wheeler Company, Bloomfield, N. J.; the Backus Electrical Company, the Newark Electric Light and Power Company, and others too numerous to mention.

Haverhill, Mass.—A "grand double-track electric street railway" between Haverhill and Nashua, N. H., is one of several such projects presented to the board of trade; the road would have connecting branches to Manchester through the Merrimack Valley, also from Salem Depot to Derry. Another line was mapped from Manchester along the north shore of Lake Massabesic to Auburn, Chester, Hampstead, Atkinson, Plaistow to Haverhill. Another proposed line is from Haverhill to Georgetown, and starting from the Haverhill and Danvers railway at Georgetown to Rowley, Ipswich, Essex, Salem and Gloucester. This shows the Merrimack Valley from Manchester, N. H., to Newburyport; also a wide range of the Atlantic coast from Gloucester to the Isle of Shoals.

Rochester, N. Y.—Tests are to be made shortly at Rochester of a method of electric propulsion for boats on the Erie Canal. The tests will be made by the Westinghouse Electric and Manufacturing Company, and will be, says the Rochester *Herald*, under the personal supervision of Lemuel Barrister, superintendent of that company. It is said that $20,000 will be expended in perfecting and introducing the invention. The power will be generated in a large storehouse at Pittsford, owned by J. M. Wiltse and leased to the Westinghouse Company. A boat owned in Buffalo has been secured and is to be fitted for use in making the experiments. The apparatus is now being manufactured at Pittsburg. It will be in readiness in two or three weeks, when it will be shipped to Buffalo, loaded upon the canal boat, together with dynamos for the power house and a 75-horse power engine, by which they will be operated, and with this cargo the boat will steam down to Pittsford and active work will begin.

Awards to the Dixon Company.

Judges appointed by the officials at the World's Fair at Chicago have made awards to the Joseph Dixon Crucible Company, Jersey City, N. J., for superior products in graphite, lead pencils, plumbago, crucibles, black-lead stoppers and nozzles, dippers, bowls, foundry facings and lubricating graphite.

These awards are a very proper recognition of the qualities of these goods, as the Dixon Company is known throughout the world as the pioneer in the graphite industry and its goods are always considered as the standard. The United States Government in its bids for supplies says, "Dixon's or equal."

Eureka Tempered Copper.

The Eureka Tempered Copper Company of North East, Pa., who are the only manufacturers of pure tempered copper, have found an extensive field for their well-known products in electrical work, as outside its value as an anti-friction metal for journals, etc., tempered copper has proved its superiority for commutators, brushes, contact springs, and many other parts of dynamos and motors.

The company make a specialty of commutator bars, which are cast of pure copper, rolled and hardened, and the metal thus finished has great toughness and pliability, so that in addition to the superior conductivity due to the absence of all alloys, its wearing qualities adapt it perfectly for use in commutators.

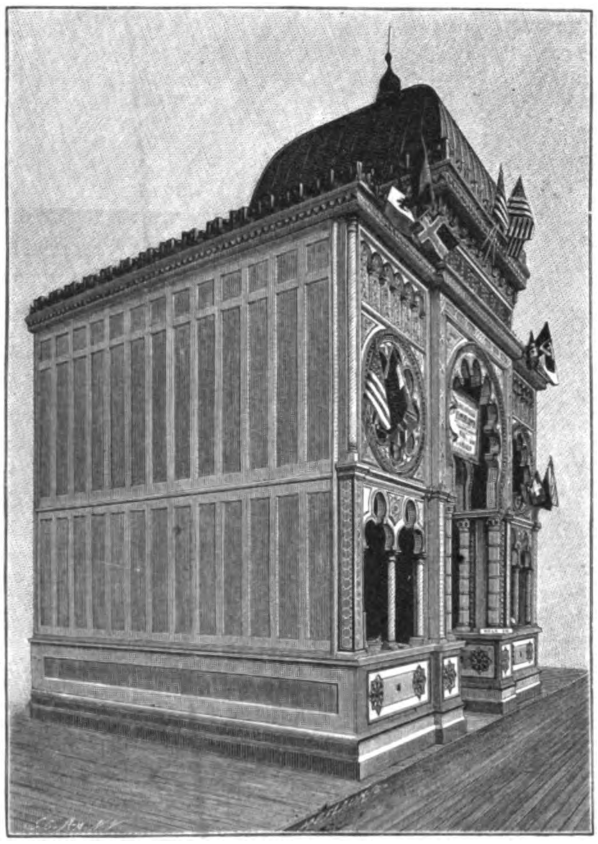

FIG. 1.

The illustration above (Fig. 1) shows the pavilion at the World's Fair in which this company have an elaborate display of their copper goods, whose merits have been recognized by both the Franklin Institute of Philadelphia and the Jury of Awards of the World's Fair. By the former, tempered copper was awarded the John Scott Medal and Premium after a thorough investigation, and the World's Columbian Exposition has also awarded the Medal for Copper for Electrical Purposes, the award reading as follows:

"Tempered copper for use in electrical construction, consists of cast and wrought copper for use in the electrical industries. The mechanical strength and wearing qualities of this copper have been shown to be considerably superior to ordinary copper, cast or rolled.

"The treatment which the copper receives is a distinct advance upon ordinary copper working, as through it sound castings of commercially pure copper are secured without failure.

"The castings may be tempered to any degree of hardness between considerable units, and they may be made forgable by the ordinary processes. The exhibit is worthy of an award for excellence in cast, tempered and forged copper."

Fig. 2 shows a view of the interior of the Eureka Company's pavilion, in which is displayed some of the numerous tempered copper goods which they manufacture. Among these are commutators, contact springs, bearings, trolley wire, lathe steps, soldering irons, dynamo brushes, pinions and other articles too numerous to mention.

One of the most important points in the copper so prepared is its chemical purity, of which the examining committee of the Franklin Institute speak as follows:

"The chemical examination shows that the samples are commercially pure copper. Mechanical examination bears out the statements of the applicants as to the purity of their metal. We are of the opinion that the Eureka Tempered Copper Company has made a decided step in advance in the preparation of copper for many industrial uses."

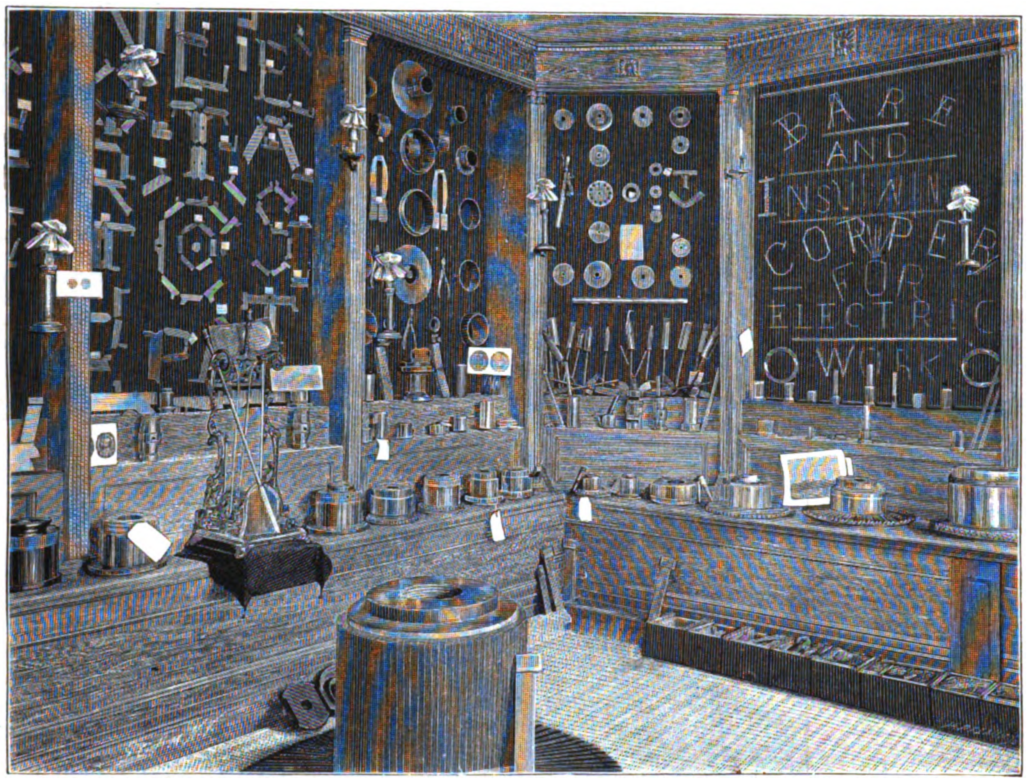

FIG. 2.

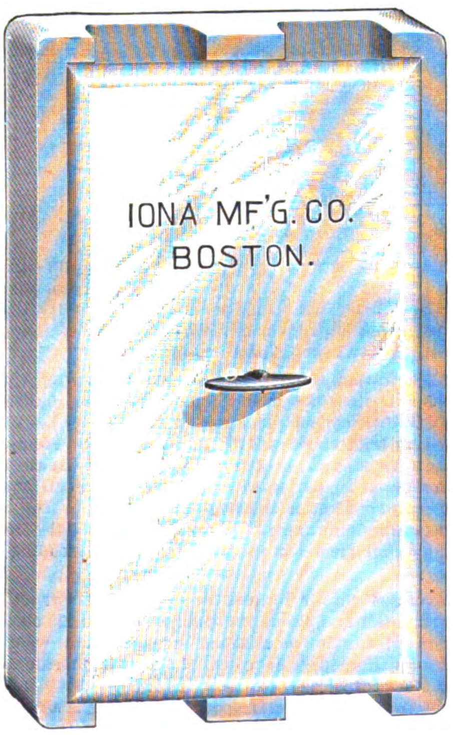
The Iona Covered Cut-Out.*

We illustrate below a new style of covered main cut-out which is being introduced by the Iona Manufacturing Company, of Boston, which possesses several features desirable to the practical wireman. The wire contacts are large and very strong. The porcelain cover can be readily removed by unscrewing the thumb nut when it is necessary to replace the fuses. The Iona Manufacturing Company will soon have a full line of these cut-outs, both branch and main, ready for delivery, and already report a brisk inquiry for them.



COMMERCIAL PARAGRAPH.

Probably the largest single order for Insulated Wire ever placed in this country was recently given the Washburn & Moen Manufacturing Company of Worcester, Mass., by the Brooklyn City Railway Company. This order included 180 miles of 500,000 C. M. Stranded Weatherproof Feed Wire, together with thirty miles of another size. The order amounted to nearly $300,000, and represented a weight of about 2,000,000 lbs. They have also obtained nearly all of the Brooklyn City Railway business during the last year, and the securing of this immense order was due wholly to the very satisfactory manner in which the orders have always been handled. The business of the Insulating Department of the Washburn & Moen Company is daily increasing, and they have recently erected a large and well-equipped factory, which during the recent depression in business has been running nearly full time.

INCORPORATIONS.

The Carpenter Electric Power and Light Company, East St. Louis. Capital stock, $2,000,000. Incorporators: Hiram H. Carpenter, Ephraim C. Dawes and James C. Brush.

The Safety Trolley Improvement Company was organized in Brooklyn, N. Y., on the 18th inst. Carl Peterson was elected president, Thomas I. Williams secretary and treasurer, and Vincent A. Strawson general manager. The capital was fixed at $200,000. Among the men interested are John F. McNamee, William R. Tinsley, a Texas capitalist, President Lewis, of the Brooklyn Heights Railroad, and Dr. Weld. Patents have been secured in this country, England, France, Germany and Belgium.

Pacific Coast Printing Telegraph Company, Los Angeles, Cal.—to manufacture and deal in printing telegraph machines and electrical appliances and operate lines and exchanges. Capital stock, $1,000,000. Promoters: Forbes Parker, Daniel Potter, Daniel Stone, San Diego, Cal.; Cleveland F. Dunderdale, Chicago, Ill.; Matthew T. Aller, Los Angeles, Cal.

The North Scranton Transit Company, Scranton, Pa.—to construct and operate an electric railway in the city of Scranton. Capital stock, $9,000. Promoters: Louis Morel, Jno. H. Fellows, H. Weinschenk, Scranton.

The Empire Electric Company, Chicago, Ill.—to manufacture and sell electric lamps and electric appliances. Capital stock, $15,000. Promoters: David A. Bennett, Henry G. Hinkle, Gustave Schroeder.

The Taylor Switch and Signal Company, Chillicothe, Ohio—to manufacture and sell railroad switches and signals and electrical and other machinery for operating same and for various purposes. Capital stock, $24,000. Promoters: John D. Taylor, Richard Enderlin, Chas. A. Smith, John M. Vanmeter, William M. Tulleys.

The Charles S. Solomon Company, Camden, N. J.—to manufacture, construct, erect and repair machinery and apparatus for electrical and mechanical purposes, etc. Capital stock, $30,000. Promoters: C. S. Solomon, W. S. Griffiths, J. S. Mount, Philadelphia, Pa.; A. H. Gangewer Burlington, N. J.

The Jamaica Electric Light Company, Jamaica, L. I.—to furnish heat and power to villages of New York State. Capital stock, $15,000. Directors: George R. Culling, Mount Vernon; William S. Williamson, Jamaica, and Alonzo B. Pettitt, Jamaica.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 10, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

506,468. Electric Railway Trolley. George H. Benjamin, New York, N. Y., assignor to Siemens & Halske, Berlin, Germany. Filed June 30, 1893.

506,492. Trolley. George F. Green, Kalamazoo, Mich., assignor of one-half to Oliver S. Kelly, Springfield, Ohio; Martha L. Green executrix of said George F. Green, deceased. Filed April 28, 1892.

506,617. Trolley Support for Electric Railways. Johan M. Anderson, Boston, Mass., assignor of one-half to Albert Anderson, same place. Filed April 14, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

506,287. Electric Car Lighting System. Frank E. Kinsman, Plainfield, N. J. Filed Sept. 18, 1890.

506,459. Carbon for Electric Arc Lamps. Royal E. Ball, New York, N. Y. Filed April 28, 1892.

506,488. Electric Light. George Fitch, Millvale, Pa. Filed April 18, 1893.

506,503. Electric Arc Lamp. Carl Hoffmann, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 5, 1893.

506,650. Carbon Electrode for Arc Lamps. Joseph M. Lacombe, Paris, France, assignor of one-half to Louis G. Dreyfus, Santa Barbara, Cal. Filed Aug. 27, 1892.

DYNAMOS, MOTORS, ETC.

506,208. Electric Motor. Job A. Davis and Robert A. Fowler, Philadelphia, Pa., assignors to the International Printing Telegraph Company, Camden, N. J. Filed Dec. 23, 1892.

506,209. Electric Motor. Job A. Davis and Robert A. Fowler, Philadelphia, Pa., assignors to the International Printing Telegraph Company, Camden, N. J. Filed Dec. 23, 1892.

506,282. Electro-Magnet. Illius A. Timmis, London, England. Filed Feb. 1, 1893.

506,358. Electric Locomotive. Johan F. S. Branth, New York, N. Y., assignor of two-thirds to Edward H. Johnson, same place. Filed March 23, 1892.

506,481. Fan Motor. Chaimsonovitz P. Elieson, New York, N. Y., assignor of one-half to Francis A. Pellas, Ogebbio, Italy. Filed July 16, 1892.

506,482. Regulator for Dynamos. William H. Elkins, Cambridge, Mass. Filed Feb. 27, 1893.

506,577. Electrical Transformer or Induction Device. James M. Adams and Martin Adams, Elkhart, Ind. Filed June 22, 1893.

BATTERIES, ETC.

WESTERN ELECTRIC COMPANY'S WORLD'S FAIR EXHIBIT. (See Page 186.)

World's Fair Notes.

Western Electric Company's World's Fair Exhibit.

ELECTRIC LIGHT APPARATUS AND ELECTRIC LIGHTING.

The exhibit of the Western Electric Company may be divided into two classes, one of which is used by the Exposition itself for lighting its own grounds and buildings, and the other is operated by the Western Electric Company for use in its own exhibit in Electricity Building.

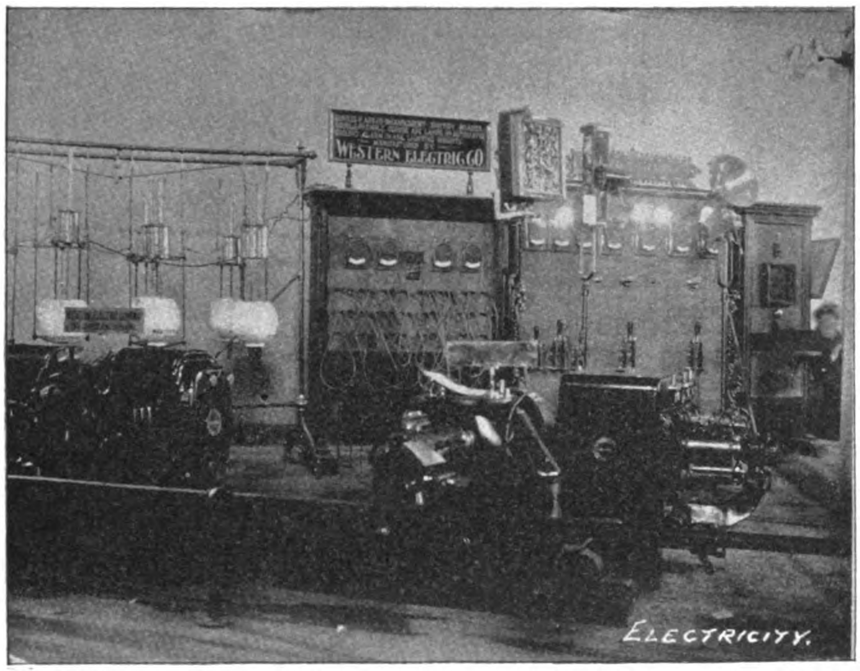

Exhibit of Switchboards.

In order that this article may be more comprehensive, we will begin by describing the portion which is operated by the Exposition. Their plant consists of ten Western Electric arc dynamos, each having a capacity of fifty nominal 2,000 c. p. arc lamps. These machines are built with the latest improvements, being entirely automatic in their action, permitting of change in load from nothing to full capacity without injurious heating or excess of sparking. The machines are of constant current type, operating the lamps in series. In building these machines it has been the design to use a construction which would require a minimum amount of attention from the operator, and in order to do this it is necessary to discard oil cups and provide a means for lubricating the commutator. To accomplish this end, self-oiling ball and socket bearings were designed, which not only lubricate their own bearings but also take perfect alignment with the shaft, thus preventing the bearings from becoming hot. The old-style copper brushes are done away with and carbon brushes substituted in their places which in themselves lubricate the commutator sufficiently to permit it to run 24 hours without attention. The automatic regulator, which is at all times connected with the machine, will operate to detect the variation of ¼ ampere from the normal output of the machine and correct the same at once, the result being a machine which requires little or no attention from the operator. By means of a switch located on the machine the normal output of the dynamo can be varied from 10 amperes to 8 or 7, as desired, so that with the same dynamo and the same lamps any candle power desired can be produced. The machines are also constructed so as to make each part accessible, and with this in view the bearing seats are so constructed that one bolt is sufficient to hold a bearing rigidly in place. It is possible with this construction to stop a machine which is doing full duty, and place the armature upon the floor, in not to exceed three minutes' time. The regulation of this machine is accomplished by shifting the brushes around the commutator as the load changes, thereby producing a constant current output from the machine. Any variation in the current output is immediately remedied by a small electro-magnet through which passes the full current of the machine. The dynamo is mounted upon a wooden sliding adjustable belt tightener, the wooden frame serving to insulate the machine from the foundations. The commercial efficiency of these machines at full load is not less than 90 per cent., and the heating, when operated for any length of time, will not exceed 90° Fahr. above the surrounding atmosphere.

The dynamos are connected to the lamps through a Western Electric arc lighting switchboard made of Tennessee marble. Upon this marble are mounted springjacks, to which are connected the various circuits. Half the jacks in this board are devoted to the service of the Exposition and the other half to that of the exhibit of the Western Electric Company in Electricity Building. These springjacks are constructed in such a manner that any circuit can be short-circuited at the switchboard by means of a disconnecting plug. With this device any circuit can be cut into or out from service while the dynamo is in operation without interfering with the lamps not intended to be affected by this operation. In connection with this board is a testing device by means of which the insulation resistance to ground of any circuit can be measured while the lamps are burning.

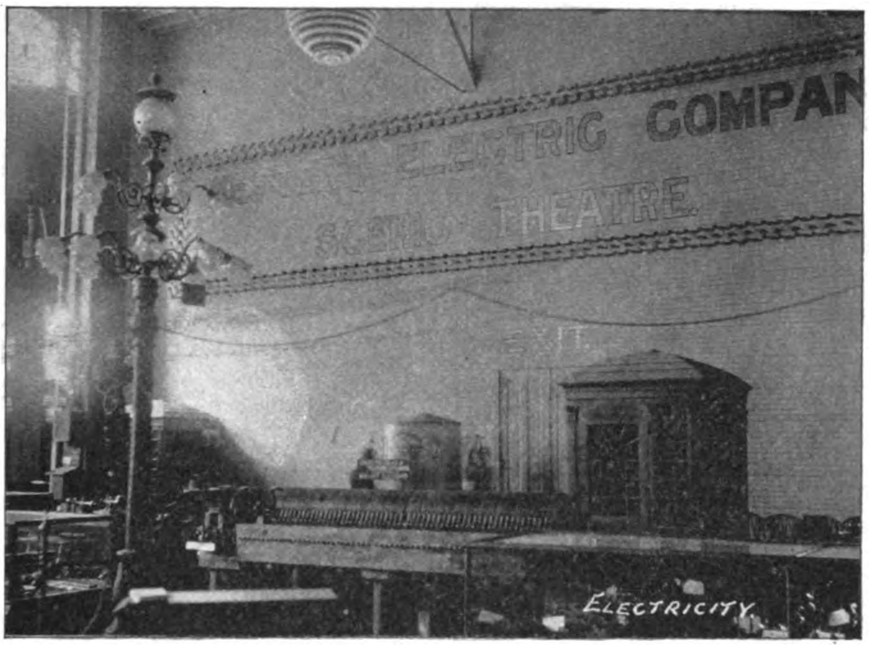
This switchboard consists of brown Tennessee marble 14 feet long and 6 feet high, surmounted with Japan lacquered cap and a handsome eight-day clock in grille work which is located in the centre of the board. The front of the board is finished in the most perfect style of art, no detail being overlooked to make the board complete. The back of the board is not less highly finished. All connections for the arc circuits run up through the floor and are fastened to small porcelain insulators which are held to the board by means of small brass brackets, and thence run to their respective springjacks. All the connections for the incandescent apparatus are made of heavy brass castings, which are finished in Japan lacquer, to which all the circuits are connected beneath the floor. This board is held rigid by means of large grilled bronze brackets, making on the whole a very perfect piece of work.

The apparatus in Machinery Hall which is devoted to the use of the Western Electric Company in Electricity Building consists of two dynamos each operating 50 nominal 2,000 c. p. arc lamps.

It was agreed between the World's Columbian Exposition and the Western Electric Company, prior to the opening of the Fair, that the Exposition should furnish foundations for engines, dynamos, and free steam during the period of the Exposition, and that the Western Electric Company should provide engines, dynamos and operators. As a result of this agreement the Russell Engine Company, Massillon, Ohio, installed two 200 h. p. engines and one 100 h. p. engine for this service, and the Graton & Knight Manufacturing Company, Worcester, Mass., supplied the belting.

These generators and dynamos are directly connected to the switchboard heretofore described. The distance between the power plant in Machinery Hall and the exhibit of the Western Electric Company in Electricity Building measures a trifle over 2,500 feet. It was decided that the 220 volt direct current system would give the best results, and this system was adopted by the company. The circuits extend in the subway between the floors, and the wire was made in 1,500 and 1,000 feet lengths, so that only one joint was necessary to make a complete circuit to the Electricity Building. This arrangement brought all the joints beneath the floor in Machinery Hall, where it is perfectly dry. Special clips were made for fastening these circuits to glass insulators, the old style tie wire being abandoned. The result of this is that the insulation resistance to ground, even in a very wet tunnel, has at all times been over or about a megohm, and grounded circuits rendered an impossibility. The circuits are all run into a switchboard in Electricity Building, which is similar to that in Machinery Hall, being composed of brown Tennessee marble, 12 feet long and 6 feet high. It is designed to be as perfect a piece of switchboard distribution as it is possible to construct. The back of the board is finished in an elaborate manner, all brass and copper trimmings being polished and copper plated. The positives and negatives of the incandescent circuit are connected directly to bus bars, from which distributing circuits run through double-pole knife switches and ammeters directly to the lamp circuits. The accompanying photograph shows the arrangement of one side of the board. One end of the board is devoted exclusively to the distribution of arc circuits, there being 150 arc lamps of the Western Electric Company's manufacture in Electricity Building. Seventy-five of these lamps are devoted to the service of lighting various portions of the building, and thirty of them are placed on Columbian lampposts, manufactured by the Western Electric Company, which are located in the galleries and main floor.

The Western Electric Company's exhibit in Electricity Building consists of a display of artistic effects produced by electric lighting, as well as wares manufactured by its various factories. The exhibit is located in the southeast corner of the building, Section A, Spaces 3, 4 and 5. Located at the north end of the exhibit is a large glass sign reading "Western Electric Company, Chicago, New York, London, Antwerp, Paris and Berlin." This sign is 22 feet long, 8 feet high and 4 feet wide, reading on both sides. The interior of the sign is lighted with 14 arc lamps. The letters are formed of various colored glass crushed into small pieces, and the lamps, swinging continually, cause a scintillating effect resembling that of diamonds, rubies, sapphires and emeralds, making a very attractive display. The office of the company is located in the northwest corner of Space 4. It is of Grecian style of architecture. The interior is divided into two rooms, the front one being a drawing-room and the rear one a private office. The illumination of this office is novel in the extreme, the front room being the green room and the rear one the yellow room. The lighting is entirely concealed behind a frieze of paper over which is placed a light cloth of the same tint as the room. The paper forms a design back of which are placed the lamps, thus giving an appearance of an illuminated wall, and bringing out the design in an artistic manner. The effect is novel and original. In the front portion of the building is placed an elegant painting on glass, nine feet high and six feet wide, entitled "Fairy Queen," the lighting of which shows the evenness with which light can be distributed over a surface of this size. In the front room are also located two miniature fountains placed in glass globes three feet high and sixteen inches in diameter. Six colors are reflected through the water, which is thrown in small jets to the tops of the globes. The action of the fountains is entirely automatic, being regulated by clockwork.



Automatic Switch for Lighting Effects.

Upon entering the south entrance of Electricity Building the visitor is attracted to the Egyptian Temple. The exterior of this building is covered with interesting allegorical figures representing Egyptians in the performance of all kinds of electrical work. The inside of the building serves as a show room for the display of various electrical instruments. The building is divided into two rooms. The larger room has a ceiling composed of stencil cut paper and covered with a fine texture of cloth, while the coves are studded with ruby glass jewels behind which shine incandescent lamps. The tint of the room is green and the walls are frescoed in stencil work apparently representing Egyptian decoration, but a close examination reveals the fact that the figures themselves are composed largely of electrical apparatus. In the four corners and in the centres of the sides are green glass columns about two feet in diameter, the walls of which are three inches thick. These columns are lighted from the interior by incandescent lamps, giving a brilliant effect. Built into the walls of these rooms are recesses which serve for show cases which are lined with red plush and lighted from above. In these cases may be seen all kinds of electrical apparatus and instruments. On the walls of the room there are numerous medals which have been awarded to the Western Electric Company at the Paris, Philadelphia, Australia and a number of smaller Expositions.

Passing through this building the observer is attracted to a rapidly rising band of light around a column two feet in diameter and over twenty feet high, which is studded with red, white and blue lamps, and from the top of which extend four radial zigzag arms typical of lightning. At the end of two of these arms are large revolving spheres forty two inches in diameter, studded with 300 lamps each, and revolving at a high speed. At the ends of the other two arms are conical clusters of lamps of different sizes. Periodically, throughout the day and night, bands of light three feet wide rise from the base of this column, to the summit and then pass out through the arms into the balls and cones, producing a novel effect. The balls are at one instant filled with red light which suddenly changes to white and again to blue. The controlling switch is placed beneath the floor and automatically produces all these various changes. This switch consists of 137 circuits, which are connected and disconnected by means of a revolving cylinder upon which are placed cams so arranged as to make contacts at the proper time. This roller is driven by a $\frac{1}{4}$ H. P. motor. The current furnished to the column is 110 volts; it is reduced to this pressure in order to avoid arcing at the revolving switch. This change of pressure from 220 to 110 volts is made by means of a motor generator of 40 H. P. capacity which receives current directly from Machinery Hall and delivers it at 110 volts.

At the north end of the exhibit is a large cabinet, upon the top of which are placed the letters "W. E. Co." in 16 C. P. lamps, shown in the centre of the Frontispiece. Behind these lamps is a pointer operated by means of a controlling mechanism placed inside the cabinet. This arm commences at the beginning of the letter "W," passes across the cabinet, apparently writing each letter, after which it retraces its course and extinguishes the lamps in the same manner in which they were lighted.

Near this exhibit is placed another exhibit which spells the words "Western Electric Co." by moving a lighted lamp through the air.

One of the most attractive exhibits installed by the Western Electric Company is a Scenic Theatre, which is located in the extreme southeast corner of the building. (See Frontispiece.) After several plans had been discussed it was decided to reproduce in as realistic a manner as possible the natural transitions of light during a period of twenty-four consecutive hours of night and day. The scenery employed to produce these effects represents the Alps. The stage opening is ten feet wide and nine feet high. The front portion of the scene represents a village consisting of several houses and a church. During all the changes of light which occur from sunrise to sunset, including a storm followed by a rainbow, music is arranged to correspond with the different scenes and to interpret as far as possible the time of day. The circuit used is 110 volts pressure, which is furnished by means of a motor generator similar to that described for lighting the column. The scenery was designed and painted by Sosman & Landis, of Chicago.

A 20-light arc machine located directly under a sign on the Egyptian Temple illuminates this sign. It is driven by means of a 220 volt motor. This motor is of the slow speed type.

In the immediate vicinity of the dynamo display are two sample switchboards, one being for arc circuits and one for incandescent circuits, similar to those heretofore described, but intended to show the distribution of current for the various systems employed by the Western Electric Company.

Immediately in the rear of the office of the Western Electric Company is placed a large oak partition 12 feet high, on either side of which are placed counters and show cases. The partition serves as a means for displaying the large line of hotel calls, annunciator and burglar alarms of all kinds manufactured by this company.

In the main aisle, on the western side of this exhibit, and between the Egyptian Temple and the office, is an operative machinery exhibit in which is displayed special machinery invented for the purpose of meeting special demands arising in the manufacture of electrical apparatus. The first of these machines is the automatic nut machine, which manufactures nuts from brass strip, all polished, drilled, tapped, and faced off on one side and chamfered on the other. This machine has a capacity of from 8,000 to 10,000 per day, large quantities of which are used in switchboard apparatus, bells, etc., that are manufactured by this company. Next to this is a multiple drill press, consisting of 24 adjustable spindles. The machine is connected to a line shaft by means of belting, and this line shaft receives its motion from a 220 volt slow speed 10 H. P. motor of the Western Electric Company's system. In addition to this machine are seven other machines connected to this shaft, two of which are metal working machines and the others wire insulating machines. The product of this drilling machine consists of a small souvenir of white holly wood, $\frac{1}{8}$ inch thick, $1\frac{3}{16}$ inches wide, and 2 inches long. Through these small blocks are drilled $24\frac{1}{8}$ inch holes simultaneously. These holes are drilled at a uniform distance from each other, which is equal to $\frac{3}{16}$ inch; they are drilled in two rows near and around the outer edge, leaving a blank space in the centre; in the blank space on one side is stamped the inscription, "Western Electric Co. 1893," and on the other side is stamped "Drilled by one operation."

Next to this machine stands the double turreted automatic screw machine, made to work on both sides of a piece before it leaves the machine. The stock is fed in through the lower head, and the work at one end is finished, after which it is cut off and picked up by an automatic finger and placed in the upper head where the opposite end of the piece is finished at the same time that the machine performs the operation on the first end of the next piece, after which the piece is thrown out into a receptacle made to receive the finished work.

In this space are also found spooling and insulating machines, which are used in the manufacture of annunciator and magnet wire, as well as telephone cable. The cotton yarn used in covering the wire is wound upon spools, and then put on revolving heads where it is wound upon the wire, which is in turn wound upon spools ready for shipment. Magnet wire is covered in the same manner, silk being used in the place of cotton, and the heads being made to take in any size wire from the smallest up to any size desired. Here is also shown the first process of insulating wire for telephone cables, paper being used in place of cotton.

Near the centre of the southern end of the exhibit is a historical display, the special features therein being work done by Moses Gerrish Farmer, an excellent portrait of whom overhangs the exhibit. Here is shown a reproduction of what is supposed to be the first reversible motor ever produced, it having been built and put on exhibition by Mr. Farmer in Dover, N. H., in 1847. Next to this stands an old mantelpiece which was taken out of the Farmer house in Salem, Mass. The principal objects of interest on this mantelpiece are the small incandescent lamps placed upon it in exactly the same manner as arranged by Mr. Farmer in 1859. In this space is also shown a dynamo-electric machine which was made by Mr. Farmer about the year 1859.

In one corner of the space allotted to the Western Electric Company is shown almost every instrument or piece of apparatus used in telephone work. Near the entrance to the "Scenic Theatre" are the magneto call bells and allied apparatus, and at this point an examination of this very comprehensive portion of the exhibit should begin. No attempt has been made to conceal the apparatus or even to put it out of reach; the many types of magneto bells, transmitters and telephones are within reach, and can be examined and handled by all.

The familiar Blake transmitter, the ordinary Bell receiver, the Hunnings transmitter, the new "solid back" transmitter, the long distance receiver, and the various forms of switchboard transmitters and receivers are among the articles displayed. The small transmitter and receiver, together with the compact stand and call bell for use on short lines ("speaking tube system"), are worthy of a careful examination.

Many diagrams of the circuits used on the various switchboards are displayed, by the help of which the workings can be understood, and the evolution of the switchboard from its simplest form to the present complex apparatus followed. The entire display of telephone appliances is worthy of more than a passing glance even from the average visitor, while to the telephone man the careful study of the various pieces of apparatus cannot but be of profit.

Almost directly under the large illuminated sign of this company is a display of complicated apparatus for use on police and fire alarm work. This apparatus is such as is in use by many of the municipal corporations throughout the country. The most striking objects in this part of the exhibit are the three full size police booths, in general outline like those to be seen on so many street corners of Chicago and other cities. These exhibition booths are finely finished, of oak, surmounted by polished copper domes upon which lamps with many colored shades throw a brilliant light. Two of these booths are provided with "double" signal boxes, one part for use from the outside, for sending in simply an alarm of fire or call for help from the station, the other part for use from the inside of the booth, permitting the sending of several distinct signals or of telephonic communication. The third booth has the inner box only, showing the different methods of using the signalling apparatus. On a wall just back of the booths are several kinds of signal boxes for use on street corners, in banks, or other business places, as well as the smaller and more handsomely finished boxes for use in residences.

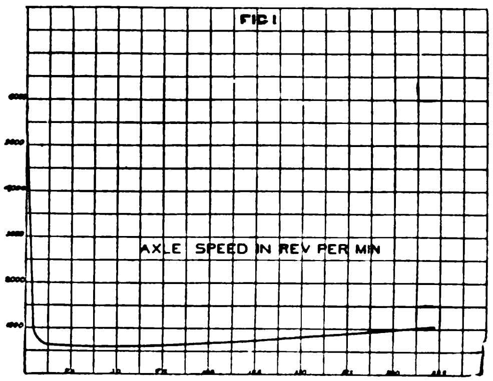
The exhibit of insulated wires and cables comprises a full line of magnet wires of various sizes, with silk and cotton insulation; office and annunciator wires; flexible conducting cords of various numbers of conductors; switchboard and office cables; "underwriters" and "weatherproof" wire; and underground and aerial cables for telegraph, telephone and electric light service. In addition to the finished product, machines are shown in operation covering wires with silk, cotton and paper, and the cable exhibit comprises terminals, model splices and branches, and a complete cable laying apparatus for underground cables. A complete cable laying outfit is exhibited, showing a couple of brick manholes sunk below the floor, with main conduits and branches, and with cables in position and splices in different stages of completion. A wagon with a full kit of tools stands between the manholes, and a reel of cable on a stand is in position to be drawn into a duct at one manhole while a capstan with all the necessary apparatus is at the other.

Taken as a whole, the exhibit of this company constitutes one of the most extensive, popular and instructive displays to be seen at the Fair.

Special Paper on "Traction and Street Railway Trucks."

BY ELMER A. SPERRY.*

The adhesion between the car wheel and rail is really friction of quiescence. In studying the laws governing both friction of quiescence and friction of motion one is struck with a peculiarity in the curves; notably so when metallic substances are undergoing examination. The curve shown in Fig. 1 illustrates this for a rail and wheel supporting about 3.200 lbs. The most cursory examination of the curve will at once show that the characteristic is by no means one of gradual or proportionate transition from a state of quiescence to that of motion, but, on the contrary, a breaking away with a wonderful suddenness of drop from high values to those which are very low.



Without recounting those experiments which have forced me to the following deduction, I will state that in my opinion what we know as friction of quiescence or adhesion between a wheel and a rail consists essentially of molecular gearing, the teeth of which, though minute, are as positively in mesh as those of the regularly organized gear. I have found the adhesion to be maximum when the substances are alike, under these conditions the aforenamed molecules or irregularities probably being very similar as to dimensions. By this statement it is not meant that the highest values are necessarily attained under conditions of like materials, but that the lines connecting the higher and lower values are more nearly vertical, arguing more complete intermeshing, hence in shearing a more sudden giving away of the molecular teeth at the time of dropping from the high to the lower values. The curve in question is drawn to scale, and graphically portrays the extremely low values in terms of traction or drawbar pull upon the dynamometer of the slipping wheel, as compared with the wheel rolling upon the track without slip. This curve was obtained in determining by trial the grade at which forwardly revolving slipping wheels would just balance the tendencey of the weighted car to slide down the grade. Space does not permit multiplying data and curves, all of which prove the importance of preventing the slipping of traction wheels. The insight afforded by these curves leads to revelations which are at first startling to the investigator, and in the judgment of the writer the present investigation should be followed by others in this most important field. The curve shows the instant of starting to slip to be the critical point, and the problem is preeminently one of preventing the wheels in question from starting to slip.

How can this be best accomplished?

The writer has made a number of tests which may be of interest in this connection, and which show that there is a possibility of improvement upon methods which we at present accept as standard. The oldest method of accomplishing this purpose has been to couple all the drivers for absolute harmony and uniformity of movement, so that the tendency of one driver to slip will be checked by all the others instead of by its mate only. The question being, Do we find in practice the coupling of the wheels in this way to accomplish the desired result—does it in any way increase the traction?

Experiments have been made to determine this question, including a bi-axled equipment of the ordinary kind with an independent motor for each axle, and also equipments consisting of four, six, and as high as eight separate drivers locked together to revolve in unison, being supplied with a single motor or source of power. I have found the method employed in coupling the wheels to seriously affect the traction appearing as drawbar pull. For instance, if locomotive connecting rods are used, the necessary flexibility of truck for parallelism of axle must be entirely sacrificed, as if allowed to exist it produces a continually and constantly recurring tendency to slip, resulting in a change from compression to extension of all the strains in both the truck and connecting rods. This change occurs twice in each revolution of the system, and results in a slip alternately of the wheels upon each side in amount dependent upon the lost motion existing. I have seen experiments where this periodic slip amounted to as much as five-sixteenths of an inch, occurring twice each revolution, when working upon a grade without trailers.

This is avoided by steam locomotive engineers by holding the axles in absolute parallelism in a plane normal to the roadbed, and until within the last few months English locomotive builders have maintained that the parallelism of driver axles should be absolute.

As to the street car truck, the flexibility necessary argues the employment of belting or rope transmission, which easily and naturally permits of such flexibility. I am free to say that no one who has not tried this experiment can form an adequate conception of the tremendous strains which motor gearing is called upon at times to withstand. I have seen as many as fourteen parallel strands of rawhide rope under very heavy tension in forty-five degree grooves slip and burn in their efforts to do work under conditions where gears are ordinarily employed, the gearing doing its work with perfect ease. No form of friction drive or friction gearing is admissible for this work. The chain drive was the first to be employed in this country, but was early abandoned on account of noise, excessive wear and journal strains, together with the impossibility of keeping it anything like adequately lubricated.

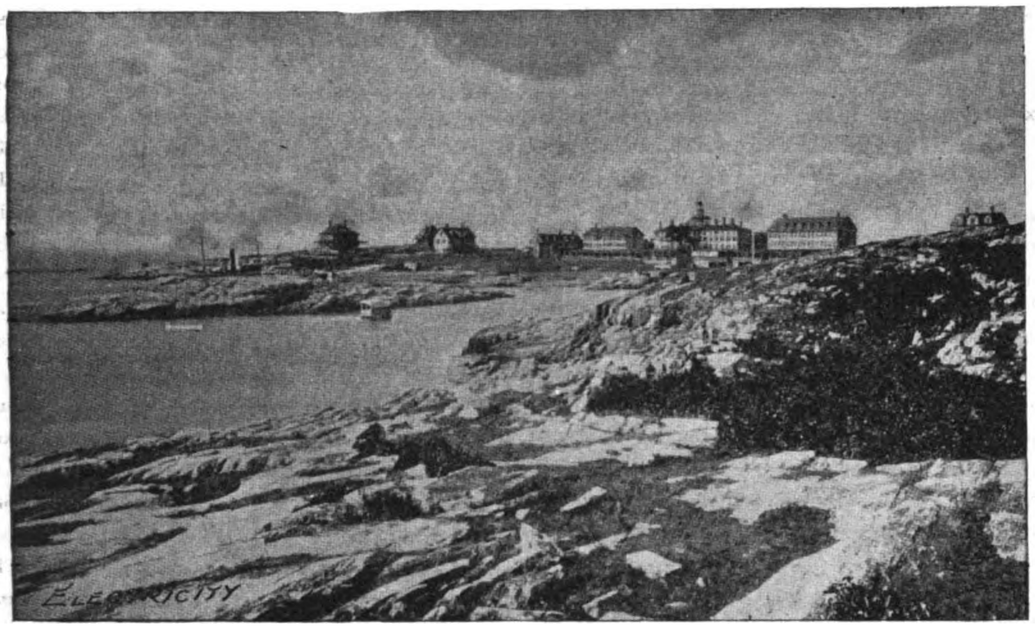
(*To be continued.*)

---

[*] Abstract of paper read at the American Street Railway Association Convention, Milwaukee.

The Isle of Shoals Cable.

There has been for many years one place at least on the picturesque coast of New Hampshire where the business man after escaping from the hurly-burly of competitive strife, the rancor of exchange, mart and office, could hie himself away even beyond the reach of the post-office, the telephone, the telegraph, the newspaper and the railway train, and commune with Nature in one of her quietest retreats. That place is the Isles of Shoals, situated a few miles off the New Hampshire coast, one of the most charming marine resorts New England can boast of, and that is saying a great deal.



Appledore Island.

This group of islands has won a world-wide reputation for its quietude and invigorating air, and for years past there has been a constantly increasing number of visitors there from many parts of the United States. All who wended their way thither were fully confident of finding a temporary Elysium where they could rapidly recuperate their physical strength while giving the mental powers a complete and much needed rest.

Appreciating the future of prosperity that would inevitably open up for such a resort, men of enterprise were not slow to make provision for the accommodation of health seekers, the outcome being the erection of one or two hotels on Star and Appledore islands, which form the larger of the group of the Isles of Shoals.

These hostelries soon became well and favorably known far and near, and enjoyed a fair patronage. The facilities for reaching the islands were provided by the Boston and Portsmouth Steamship Company, which for years has been constantly improving the service. During the last season hundreds of passengers were carried thither daily from Boston by the magnificent steamer "John Brooks," and by other boats from Portsmouth and elsewhere.

So important a summer resort have the islands now become that it has been deemed advisable to provide cable facilities, for transient patrons as well as residents, with the outer world, thereby enabling gentlemen to maintain communication with their home friends and business associates, and when necessary transact business which might be urgent.

With this end in view, a number of capitalists interested in the continued prosperity of the Isles of Shoals organized the Gardner Cable Company for the purpose of laying a submarine cable from Appledore Island to the mainland.

In April last the project had so far advanced that a contract was made with Mr. C. S. Knowles, of Boston, representing the Safety Insulated and Wire Cable Company of New York, to manufacture such a cable as was necessary.

The cable itself is $1\frac{1}{4}$ inches in diameter, containing two wires, protected by insulation, and armored with 15 strands of No. 8 galvanized iron wire. The total weight was about 36 tons.

Saturday, August 19, was the day appointed for laying this cable, and the work was successfully done, though some unlooked for interruptions somewhat impeded its execution.

The cable, on an immense truck, as shown, was shipped from New York on a barge, which was towed to its destination by the tug R. C. Veit.

On the morning of the day set nearly every soul on the islands turned out to watch the work of laying the cable.

Notwithstanding that a northeast gale had left a strong surf rolling, the work was accomplished in a few hours, telegraphic communication with the outer world being promptly established. The work of paying out the cable went on at a rate of nearly three miles an hour, the end on the mainland being first secured, the tug then steering towards the islands.

Shipping the Cable.

When it was proved that there would be some little difficulty and delay in landing the mainland end of the cable, ropes were made fast to it, and about every person present assisted in hauling on the ropes. The cable lands near the point shown in the accompanying cut, which gives an accurate view of Appledore Island with hotel and cottages.

The Postal Telegraph Cable steamer, Captain West, rendered valuable assistance. As soon as telegraphic connection could be made with the Western Union Company's line, the following message was despatched from Appledore Island to Mr. Oscar Leighton, one of the proprietors of the hotel and a director of the cable company: "You are at last connected by wire with the United States. Praise God from whom all blessings flow."

There were many distinguished visitors staying at the Isles of Shoals and all took the liveliest interest in the proceedings. In the evening there were illuminations and a ball given at the Appledore House in honor of the event.

The cable itself was a magnificent piece of work, being 36,000 feet in length. When loaded on a heavy truck for transportation from the works to the wharf where it was transferred to a barge, in New York, the whole weighed 53 tons, and to haul this mass through the streets of the metropolis no less than thirty horses were harnessed to the truck. It is said to have been the heaviest load that ever was hauled through New York City, and naturally excited much attention. The Safety Insulated and Wire Cable Company in accepting the contract and executing the work has made quite a reputation for itself, and without doubt this order will be the forerunner of many more for submarine cable.

The cable is now in regular service, giving great satisfaction, and its value as a means of communication with the mainland has already impressed itself on the minds of the authorities, so that there is a probability of a life-saving signal station being established on the islands.

The credit for undertaking this great enterprise from its very inception to its final and useful consummation, as above reported or described, is due to Mr. F. M. Ferrin, of Boston, a gentleman who, acting as representative for Mr. C. S. Knowles, has most efficiently and skilfully carried out a very important task.

put on revolving heads where it is wound upon the wire, which is in turn wound upon spools ready for shipment. Magnet wire is covered in the same manner, silk being used in the place of cotton, and the heads being made to take in any size wire from the smallest up to any size desired. Here is also shown the first process of insulating wire for telephone cables, paper being used in place of cotton.

Near the centre of the southern end of the exhibit is a historical display, the special features therein being work done by Moses Gerrish Farmer, an excellent portrait of whom overhangs the exhibit. Here is shown a reproduction of what is supposed to be the first reversible motor ever produced, it having been built and put on exhibition by Mr. Farmer in Dover, N. H., in 1847. Next to this stands an old mantelpiece which was taken out of the Farmer house in Salem, Mass. The principal objects of interest on this mantelpiece are the small incandescent lamps placed upon it in exactly the same manner as arranged by Mr. Farmer in 1859. In this space is also shown a dynamo-electric machine which was made by Mr. Farmer about the year 1859.

In one corner of the space allotted to the Western Electric Company is shown almost every instrument or piece of apparatus used in telephone work. Near the entrance to the "Scenic Theatre" are the magneto call bells and allied apparatus, and at this point an examination of this very comprehensive portion of the exhibit should begin. No attempt has been made to conceal the apparatus or even to put it out of reach; the many types of magneto bells, transmitters and telephones are within reach, and can be examined and handled by all.

The familiar Blake transmitter, the ordinary Bell receiver, the Hunnings transmitter, the new "solid back" transmitter, the long distance receiver, and the various forms of switchboard transmitters and receivers are among the articles displayed. The small transmitter and receiver, together with the compact stand and call bell for use on short lines ("speaking tube system"), are worthy of a careful examination.

Many diagrams of the circuits used on the various switchboards are displayed, by the help of which the workings can be understood, and the evolution of the switchboard from its simplest form to the present complex apparatus followed. The entire display of telephone appliances is worthy of more than a passing glance even from the average visitor, while to the telephone man the careful study of the various pieces of apparatus cannot but be of profit.

Almost directly under the large illuminated sign of this company is a display of complicated apparatus for use on police and fire alarm work. This apparatus is such as is in use by many of the municipal corporations throughout the country. The most striking objects in this part of the exhibit are the three full size police booths, in general outline like those to be seen on so many street corners of Chicago and other cities. These exhibition booths are finely finished, of oak, surmounted by polished copper domes upon which lamps with many colored shades throw a brilliant light. Two of these booths are provided with "double" signal boxes, one part for use from the outside, for sending in simply an alarm of fire or call for help from the station, the other part for use from the inside of the booth, permitting the sending of several distinct signals or of telephonic communication. The third booth has the inner box only, showing the different methods of using the signalling apparatus. On a wall just back of the booths are several kinds of signal boxes for use on street corners, in banks, or other business places, as well as the smaller and more handsomely finished boxes for use in residences.

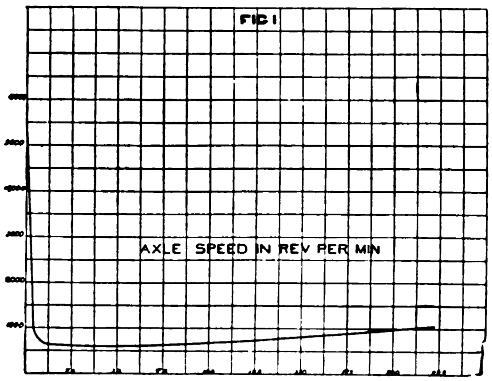
The exhibit of insulated wires and cables comprises a full line of magnet wires of various sizes, with silk and cotton insulation; office and annunciator wires; flexible conducting cords of various numbers of conductors; switchboard and office cables; "underwriters" and "weatherproof" wire; and underground and aerial cables for telegraph, telephone and electric light service. In addition to the finished product, machines are shown in operation covering wires with silk, cotton and paper, and the cable exhibit comprises terminals, model splices and branches, and a complete cable laying apparatus for underground cables. A complete cable laying outfit is exhibited, showing a couple of brick manholes sunk below the floor, with main conduits and branches, and with cables in position and splices in different stages of completion. A wagon with a full kit of tools stands between the manholes, and a reel of cable on a stand is in position to be drawn into a duct at one manhole while a capstan with all the necessary apparatus is at the other.

Taken as a whole, the exhibit of this company constitutes one of the most extensive, popular and instructive displays to be seen at the Fair.

Special Paper on "Traction and Street Railway Trucks."

BY ELMER A. SPERRY.*

The adhesion between the car wheel and rail is really friction of quiescence. In studying the laws governing both friction of quiescence and friction of motion one is struck with a peculiarity in the curves; notably so when metallic substances are undergoing examination. The curve shown in Fig. 1 illustrates this for a rail and wheel supporting about 3.200 lbs. The most cursory examination of the curve will at once show that the characteristic is by no means one of gradual or proportionate transition from a state of quiescence to that of motion, but, on the contrary, a breaking away with a wonderful suddenness of drop from high values to those which are very low.



Without recounting those experiments which have forced me to the following deduction, I will state that in my opinion what we know as friction of quiescence or adhesion between a wheel and a rail consists essentially of molecular gearing, the teeth of which, though minute, are as positively in mesh as those of the regularly organized gear. I have found the adhesion to be maximum when the substances are alike, under these conditions the aforenamed molecules or irregularities probably being very similar as to dimensions. By this statement it is not meant that the highest values are necessarily attained under conditions of like materials, but that the lines connecting the higher and lower values are more nearly vertical, arguing more complete intermeshing, hence in shearing a more sudden giving away of the molecular teeth at the time of dropping from the high to the lower values. The curve in question is drawn to scale, and graphically portrays the extremely low values in terms of traction or drawbar pull upon the dynamometer of the slipping wheel, as compared with the wheel rolling upon the track without slip. This curve was obtained in determining by trial the grade at which forwardly revolving slipping wheels would just balance the tendencey of the weighted car to slide down the grade. Space does not permit multiplying data and curves, all of which prove the importance of preventing the slipping of traction wheels. The insight afforded by these curves leads to revelations which are at first startling to the investigator, and in the judgment of the writer the present investigation should be followed by others in this most important field. The curve shows the instant of starting to slip to be the critical point, and the problem is preeminently one of preventing the wheels in question from starting to slip.

How can this be best accomplished?

The writer has made a number of tests which may be of interest in this connection, and which show that there is a possibility of improvement upon methods which we at present accept as standard. The oldest method of accomplishing this purpose has been to couple all the drivers for absolute harmony and uniformity of movement, so that the tendency of one driver to slip will be checked by all the others instead of by its mate only. The question being, Do we find in practice the coupling of the wheels in this way to accomplish the desired result—does it in any way increase the traction?

Experiments have been made to determine this question, including a bi-axled equipment of the ordinary kind with an independent motor for each axle, and also equipments consisting of four, six, and as high as eight separate drivers locked together to revolve in unison, being supplied with a single motor or source of power. I have found the method employed in coupling the wheels to seriously affect the traction appearing as drawbar pull. For instance, if locomotive connecting rods are used, the necessary flexibility of truck for parallelism of axle must be entirely sacrificed, as if allowed to exist it produces a continually and constantly recurring tendency to slip, resulting in a change from compression to extension of all the strains in both the truck and connecting rods. This change occurs twice in each revolution of the system, and results in a slip alternately of the wheels upon each side in amount dependent upon the lost motion existing. I have seen experiments where this periodic slip amounted to as much as five-sixteenths of an inch, occurring twice each revolution, when working upon a grade without trailers.

This is avoided by steam locomotive engineers by holding the axles in absolute parallelism in a plane normal to the roadbed, and until within the last few months English locomotive builders have maintained that the parallelism of driver axles should be absolute.

As to the street car truck, the flexibility necessary argues the employment of belting or rope transmission, which easily and naturally permits of such flexibility. I am free to say that no one who has not tried this experiment can form an adequate conception of the tremendous strains which motor gearing is called upon at times to withstand. I have seen as many as fourteen parallel strands of rawhide rope under very heavy tension in forty-five degree grooves slip and burn in their efforts to do work under conditions where gears are ordinarily employed, the gearing doing its work with perfect ease. No form of friction drive or friction gearing is admissible for this work. The chain drive was the first to be employed in this country, but was early abandoned on account of noise, excessive wear and journal strains, together with the impossibility of keeping it anything like adequately lubricated.

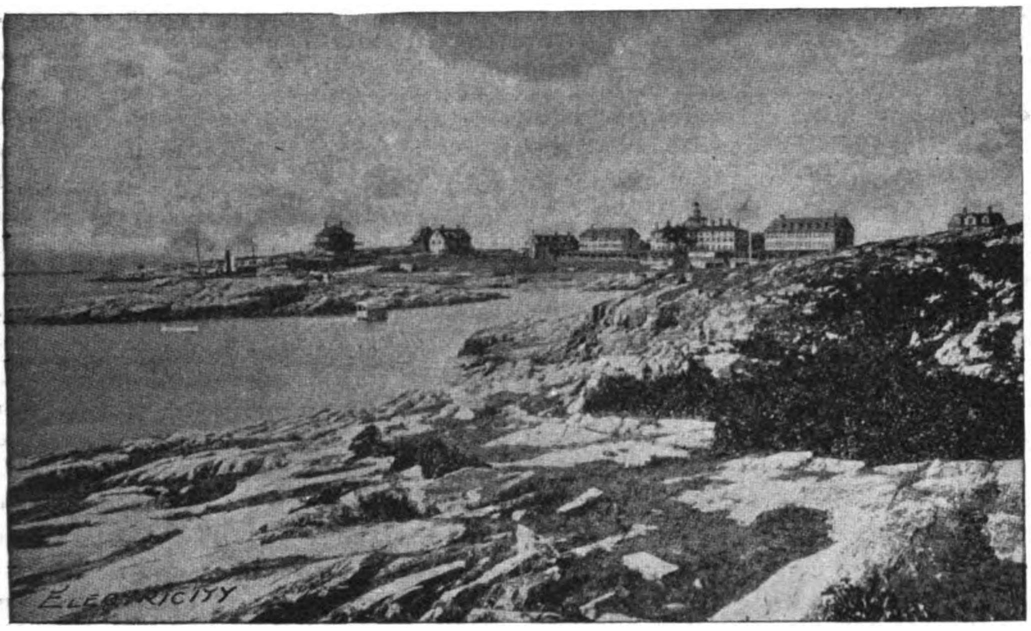
(To be continued.)

---

* Abstract of paper read at the American Street Railway Association Convention, Milwaukee.

The Isle of Shoals Cable.

There has been for many years one place at least on the picturesque coast of New Hampshire where the business man after escaping from the hurly-burly of competitive strife, the rancor of exchange, mart and office, could hie himself away even beyond the reach of the post-office, the telephone, the telegraph, the newspaper and the railway train, and commune with Nature in one of her quietest retreats. That place is the Isles of Shoals, situated a few miles off the New Hampshire coast, one of the most charming marine resorts New England can boast of, and that is saying a great deal.



Appledore Island.

This group of islands has won a world-wide reputation for its quietude and invigorating air, and for years past there has been a constantly increasing number of visitors there from many parts of the United States. All who wended their way thither were fully confident of finding a temporary Elysium where they could rapidly recuperate their physical strength while giving the mental powers a complete and much needed rest.

Appreciating the future of prosperity that would inevitably open up for such a resort, men of enterprise were not slow to make provision for the accommodation of health seekers, the outcome being the erection of one or two hotels on Star and Appledore islands, which form the larger of the group of the Isles of Shoals.

These hostelries soon became well and favorably known far and near, and enjoyed a fair patronage. The facilities for reaching the islands were provided by the Boston and Portsmouth Steamship Company, which for years has been constantly improving the service. During the last season hundreds of passengers were carried thither daily from Boston by the magnificent steamer "John Brooks," and by other boats from Portsmouth and elsewhere.

So important a summer resort have the islands now become that it has been deemed advisable to provide cable facilities, for transient patrons as well as residents, with the outer world, thereby enabling gentlemen to maintain communication with their home friends and business associates, and when necessary transact business which might be urgent.

With this end in view, a number of capitalists interested in the continued prosperity of the Isles of Shoals organized the Gardner Cable Company for the purpose of laying a submarine cable from Appledore Island to the mainland.

In April last the project had so far advanced that a contract was made with Mr. C. S. Knowles, of Boston, representing the Safety Insulated and Wire Cable Company of New York, to manufacture such a cable as was necessary.

The cable itself is 1¼ inches in diameter, containing two wires, protected by insulation, and armored with 15 strands of No. 8 galvanized iron wire. The total weight was about 36 tons.

Saturday, August 19, was the day appointed for laying this cable, and the work was successfully done, though some unlooked for interruptions somewhat impeded its execution.

The cable, on an immense truck, as shown, was shipped from New York on a barge, which was towed to its destination by the tug R. C. Veit.

On the morning of the day set nearly every soul on the islands turned out to watch the work of laying the cable.

Notwithstanding that a northeast gale had left a strong surf rolling, the work was accomplished in a few hours, telegraphic communication with the outer world being promptly established. The work of paying out the cable went on at a rate of nearly three miles an hour, the end on the mainland being first secured, the tug then steering towards the islands.

Shipping the Cable.

When it was proved that there would be some little difficulty and delay in landing the mainland end of the cable, ropes were made fast to it, and about every person present assisted in hauling on the ropes. The cable lands near the point shown in the accompanying cut, which gives an accurate view of Appledore Island with hotel and cottages.

The Postal Telegraph Cable steamer, Captain West, rendered valuable assistance. As soon as telegraphic connection could be made with the Western Union Company's line, the following message was despatched from Appledore Island to Mr. Oscar Leighton, one of the proprietors of the hotel and a director of the cable company: "You are at last connected by wire with the United States. Praise God from whom all blessings flow."

There were many distinguished visitors staying at the Isles of Shoals and all took the liveliest interest in the proceedings. In the evening there were illuminations and a ball given at the Appledore House in honor of the event.

The cable itself was a magnificent piece of work, being 36,000 feet in length. When loaded on a heavy truck for transportation from the works to the wharf where it was transferred to a barge, in New York, the whole weighed 53 tons, and to haul this mass through the streets of the metropolis no less than thirty horses were harnessed to the truck. It is said to have been the heaviest load that ever was hauled through New York City, and naturally excited much attention. The Safety Insulated and Wire Cable Company in accepting the contract and executing the work has made quite a reputation for itself, and without doubt this order will be the forerunner of many more for submarine cable.

The cable is now in regular service, giving great satisfaction, and its value as a means of communication with the mainland has already impressed itself on the minds of the authorities, so that there is a probability of a life-saving signal station being established on the islands.

The credit for undertaking this great enterprise from its very inception to its final and useful consummation, as above reported or described, is due to Mr. F. M. Ferrin, of Boston, a gentleman who, acting as representative for Mr. C. S. Knowles, has most efficiently and skilfully carried out a very important task.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR, - - 823 Monadnock Building.

BOSTON:
W S. KEY, - Room 75, 520 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

Telephone Patents Again.

We still continue to receive inquiries from a great many quarters as to the status of the telephone patents, and while we wish to oblige our readers as far as possible by answering any questions on which information is obtainable, it is manifestly impossible to authoritatively answer a number of inquiries which involve questions that are as yet undecided by the United States Supreme Court; nor can we undertake to invent or adapt a system of telephony which avoids infringing all existing patents; yet it is not impossible to do so and will be less difficult on the expiration of the Bell receiver patent, next year.

In regard to establishing exchanges to compete with systems already existing in different places, operating under the patents of the American Bell Telephone Company, it is very doubtful if such an attempt would prove successful, as the established business would for many reasons have great advantages over its rival. From the nature of the business there is hardly room for more than one telephone service in any city, as there would be naturally no connections permitted between the subscribers of the rival companies, a condition which would be as unsatisfactory to the subscribers as the divided service would be to the telephone companies.

In a city without this service, where a new system is be installed, the conditions are different. The only trouble in this case would be in arranging the details of the exchange so as to avoid infringements of patents on minor points, of which there are quite a number. For example, the switch on the magnets for ringing up the central, which is normally closed by hanging the receiving instrument on its forked handle, is patented, and without this an extra switch would need to be manipulated. Many of the details of the central station switchboards are also patented, and considerable work would be involved in arranging the details of a system which would both secure an efficient service and avoid all infringements on these patents.

Concerning the manufacture of telephone instruments there is less difficulty in the way, and for private lines there are no important obstacles in the way of patents which have not already been overcome.

It is well known that the art of telephony and the Blake transmitter are public property, and that the first patent on the Bell receiver will shortly expire. The Edison patents and the Berliner patent relating to microphones with variable surface contact are still in force, and although the validity of the latter patent has been called into question, no decision on this point has been handed down by the courts. The use of a permanent magnet in the transmitter is also patented, but this is not of much importance as an electro-magnet may be used there with equally good effect. The variable contact microphone is also not an absolute essential, although it is undoubtedly the most convenient device that can be adopted. This can be replaced, however, by a microphone in which the conductivity is varied by the changes of density in the carbon or other material due to varying pressures but with a fixed contact surface. This has been accomplished in various ways, among others by the compression of a carbon spiral.

As the matter stands now, telephones of the pattern at present used by the Bell Company cannot be generally manufactured, but enough of the patents on these instruments have expired to permit the free manufacture of very serviceable and effective instruments for this purpose.

……o……

Electric Line Construction.

There is no branch of electrical work that has undergone such a radical change as that of construction work both in the department of house wiring and outside lines. With the former the change has been brought about largely by the increasing demands of fire underwriters, while in the matter of street lines the improvement in construction is due chiefly to the demands of æstheticism, although in a few cases accidents on overhead lines have accelerated the movement in the direction of underground construction.

The experience of a number of illuminating companies in New York City at the time all overhead wires were ordered to be buried was, in many respects, a trying one, as at that time very little experience could be brought to bear on what was then a practically untried problem. In time, however, most of the overhead wires were buried, and in spite of the large expense which this involved, it is safe to assume that not one of these companies would willingly return to the old and poorly insulated aerial lines which were abandoned only under compulsion. For large cities, underground lines are now generally specified by municipal regulations, and for these the standard of insulation is maintained at a figure unthought of for overhead lines. The cost of conduits and of the extra insulation for this work is enormous in comparison to the cost of overhead lines, and it is only in a few of the largest cities that sufficient business is done to warrant such an investment. In a good many places, it must be admitted, the companies operating overhead lines have brought this extra expense of burying their wires upon themselves by permitting the overhead lines to remain in a most disgraceful condition, both as to insulation and general appearance, and in order to prevent the demand for underground wires from becoming general, which would mean bankruptcy for a good many companies, it behooves them to take the greatest care in the construction and maintenance of their overhead lines. Although in a large system this change may prove economical in the long run, the first cost of it is enough to warrant almost any company in avoiding it if possible, and in order to do so the overhead lines must be made as unobjectionable as possible. The public are now assured of the feasibility of underground construction, and will be pretty sure to demand it if overhead lines are not kept in thorough order.

……o……

THE General Electric Company on October 27 made a formal announcement that the November dividend would be passed, but failed to state when dividends would be resumed.

The Packard Lamp Factory Reopened. By reference to our news columns our readers will see that the Packard lamp factory at Warren, O., which was closed in July by injunction, has been reopened, and that the company is prepared to supply standard incandescent lamps in any quantities, guaranteed to be entirely independent of the Edison patent.

Thus the long coveted monopoly of the General Electric Company in incandescent lamps recedes farther and farther from their grasp.

The field is open, and we welcome the Messrs. Packard, who also announce a new style of lamp, the "Mogul," which is to be made in sizes hitherto unattempted.

……o……

THAT was an interesting circular sent out by Mr. Coffin a few days ago, announcing that the common stockholders in General Electric might share in the benefits of the much-talked-of syndicate which has bought about $12,000,000 of General Electric securities for $4,000,000. The circular failed to explain how it came about that the stockholders are compelled now, in order to protect themselves, to buy something which already belongs to them and for which they never received any compensation. Mr. Coffin's literary effort would have been far more interesting to electrical people if he had included a list of the securities sold. The fact that the rights to subscribe to the stock of this syndicate are selling at a premium of ¼ of 1 per cent. only would indicate that a few gems from Syracuse, Little Rock, Pueblo or Fort Worth have been sandwiched in with the really good securities.

……o……

WE HAVE remarked several times that, in our judgment, Mr. R. T. McDonald is a slicker man than Mr. C. A. Coffin. There are many who agree with us, and many who do not. The opposition has gained strength in the last few days, because Mr. McDonald has been arrested first for crime, while Mr. Coffin has only been indicted. We, however, stand by our original opinion, as we believe Mr. McDonald to be an unfortunate and innocent victim of adverse circumstances. He fell among thieves when he became a stockholder in the Madison Square bank by borrowing the money from the bank with which to pay for his stock. We hope the courts will take our view. Ravvy and Caddy have worked the public too long in company to be separated now by prison walls. We prefer to have *both* of them at large, contributing, as they always have, to the gaiety of life. But if Ravvy must go to jail, by all means let Caddy go with him.

……o……

THE HUMOROUS editor of the *Electrical World*, in supplying titles for the illustrations of the Milwaukee Convention exhibits, apparently attempted to escape criticism by making them as indefinite as possible. In one instance, however, his humor is almost too subtle to be easily explained. In an illustration entitled "The Largest Belt in the World in Actual Operation," a large belt is shown closely coiled and standing on the floor.

Is this the "actual operation" for which this belt was designed, or have we missed the joke?

THE General Electric Company announced some months ago that they had practically secured the Niagara contract. But "things got by fraud abide not," and the theft of the blue-prints miscarried.

……o……

RECENT events indicate that Mr. R. T. McDonald, like Mr. C. A. Coffin, regrets his attempt to soar as a capitalist in this great and bustling metropolis. He was very successful when the scene of his activities was confined to the rural districts, and scores of aldermen throughout the land remember with pleasure and profit his warm and substantial handshake. New York is no place for a pious and unsophisticated countryman like Mr. McDonald. There are too many newspapers here, always ready to blast a man's reputation whenever the opportunity rises. And the worst of it all is, we fear, Mr. McDonald has utterly ruined his chances of succeeding Mr. Coffin in the Presidency of the General Electric Company.

……o……

IT IS said in Chicago that the once placid features of Mr. B. E. Sunny have taken on a troubled look since "Stockholder" began a series of articles for ELECTRICITY. Important instalments may be looked for shortly.

……o……

THE wrong blue-prints were stolen. The General Electric Company should have stolen the drawings of Dr. Sellers and Prof. Forbes.

……o……

THE FINANCIAL editor of the *Daily America* believes the recent advance in General Electric is unwarranted by the actual value of the stock. He says:

> Taking the present earnings of the property, and allowing for the debenture bonds and capitalizing the earnings on a basis of 6 per cent., the present issue of stock is just about worth 30 and no more, and when the facts concerning the property are made public previous to the reorganization of the property, which is inevitable, the stock will go to just about that figure.

Legal Notes.

By a decision of the Court of Appeals at Albany, John W. Cleary obtains $3,500 from the Municipal Electric Light Company of Brooklyn and an additional $855 for costs. The plaintiff was a lamp trimmer in the employ of defendant, and February 9, 1888, received a shock that threw him to the ground. Two weeks after he received $250 from the company and afterwards his wages for four months. He at that time executed a general release, but claims he did not understand it at that time, and subsequently brought suit for $50,000. The release executed by the plaintiff was the chief point in appellant's argument.

The Bidwell electric patent case, now in the courts at Toledo, is an interesting one, as it attacks the right of the use of the trolley pole and stand in the transmission of electricity from the single overhead wire in the supply of power to street cars. A similar application for the lighting of cars is also involved in the same suit. "Mr. Bidwell, the complainant, claims," says the Toledo *Blade*, "to be the first and original discoverer of this manner of utilizing electricity, and alleges that any use of his principle is an infringement. In late years this method of street locomotion has become exceedingly popular, and wherever electric street railroad systems have been established the single wire trolley is in use. This means a big fight, as the opposition to the Bidwell claim is unlimited, and millions of dollars are involved."

In the United States Circuit Court, New York, Judge Lacombe has granted a preliminary injunction to the American Bell Telephone Company against John S. Steenburg for an infringement of Letters Patent Nos. 186, 187, granted to Alexander Graham Bell, January 30, 1877. A similar order has been asked for against Lewis H. Multer and William Harvest for violating the same patent, and a hearing has been fixed for November 3. The patents were granted to Mr. Bell for a period of seventeen years, were subsequently by assignment vested in the American Bell Telephone Company, who since have, it is claimed, the sole right to manufacture and authorize others to use telephones embracing the invention. It is said that 150,000 instrumonts are now in use, from which the American Bell Telephone Company obtains royalties.

In appointing H. C. Adams receiver of the Newton Electric Light and Power Company, whose capital stock was claimed to be $150,000, while the whole plant, it is alleged, cost but $28,000, Chancellor McGill, at the hearing of counsel in Jersey City, remarked: "There must be some pretty rough handling of these companies by the courts. They issue millions of stock, and thus deceive poor people by conveying the impression that there is abundant capital behind the concerns, but when the end comes the assets have no value. They have issued stock for patent rights that have no real or attachable values to them. These corporations are but little more than partnerships as organized under the General Corporation act, and the courts and Legislature will be soon forced so to consider them."

The Niagara Contract Closed.

The Westinghouse Company is the Winner.

End of a Long Struggle.

The Cataract Construction Company on Saturday, the 28th ult., awarded to the Westinghouse Electric and Manufacturing Company the contract for building the immense generators, etc., for the transmission plant at the Falls.

The machines are to be built from designs prepared by Messrs. Coleman Sellers and George Forbes, the engineers of the Cataract Company, and will be many times larger than any that have been built heretofore.

The apparatus will be built in units of 5,000 horse-power. The revolving field of the generators is to be constructed with inwardly projecting poles, and will revolve in a horizontal plane, being mounted upon the vertical shaft of the turbine.

The weight of the shaft, turbine and armature is to be carried by the upward pressure of the water-columns producing the heads for the turbines. The electromotive force generated will be 2,000 to 2,400 volts, and will be increased by step-up transformers for long distance transmisson and lowered by reducing transformers for distribution. The motors will be the two-phase Tesla motors, which have been found to be well adapted for power purposes. The system adapts itself readily to the use of motor generators or rotary transformers, so that it is possible to develop either single phase alternating currents or continuous currents of any desired electromotive force as may be required for the uses of individual customers.

The officers of the Cataract Construction Company include the following well-known business men: Edward D. Adams, who is president, Francis E. Stetson, Edward A. Wickes, Wm. B. Rankin and Dr. Coleman Sellers as engineer, with Prof. George Forbes, of London, as consulting engineer.

Power House Engines.*

The subject of Power House Engines for Electric Railways embraces one of the most important and interesting subjects that street-railway companies have to consider in the equipment of a power plant.

The subject represents the vital part of a street railway; as the heart forces the life current through the arteries of the body, and an impairment, or weakness of this vital organ, will produce impaired health, so also is the power house engine the vital part of the street railway, as it produces the power that creates and forces the electric current through the arteries (the trolley wire) of the electric railway, and, like the heart, if the engine regulates badly, it produces a bad circulation of varied potential, which impairs the service of the road.

The variety of opinion as to the best kind of an engine for street railway power makes the subject a difficult one on which to reach a conclusion that would not be criticised, and your committee will therefore endeavor to treat the subject impartially, and in such a manner as will result beneficially to the Association. The most essential points to be considered are as follows:

First—Perfect Regulation.
Second—Highest Economy.
Third—Greatest Durability.
Fourth—Division of Power into Units.

Good service and uniform speed of cars can only be maintained by a constant, unvarying potential, and in order to do this the engine must regulate practically perfect, so that there will be no variation of speed as the load varies The varying power required on an electric railway is unquestionably considerable, caused by cars constantly stopping and starting, going up and down grade, rounding curves, using resistance in order to run slow through crowded streets (which necessarily increases the load), and in order to have perfect service, and uniform speed of cars, the engine must be constructed so as to maintain a constant and uniform speed under any variation of load. This variation of load amounts to a very considerable fraction of the whole maximum load; in small plants it may read 95 per cent. of the maximum, and in large plants is frequently 50 per cent.

If the speed of the engine decreases when a heavy load comes on, the potential is reduced, which consequently reduces the speed of the cars, heats the car armatures, and creates an extra strain upon the machinery, which of course means an increase in the consumption of fuel, and in various other ways produces imperfect and expensive service. If the speed of the engine increases when the load diminishes, it consequently increases the voltage or potential, which is liable to result disastrously to the generators and car motors. Moreover, if the engine regulates badly, and the load diminishes suddenly, the engine is liable to "race," which is nearly always attended with more or less disastrous results.

The governor or regulator to be mechanically perfect should be made of the best material and workmanship, and should be so constructed as to control the engine under any variation of load, with a variation of speed not to exceed two per cent. An engine that will regulate within two per cent. is practically perfect for street railway work, though there are engines on the market that, on electric railroad service, can be held to one per cent. deviation from the mean speed. The governor should be constructed so as to be easy of access to all of its parts, and capable of being oiled while the engine is running. Particular attention should be given to the construction of the governor to see that there are no weak parts, and it should be so constructed as to make it the least intricate and complicated. The range of cut-off must also be larger than in engines for less variable load. This cut-off should be easily regulated between the limits of $\frac{1}{10}$ and $\frac{7}{10}$ of the stroke.

The severe conditions of high speed and sudden and extreme variations of load make it especially important that the engine have the best possible construction, with extra weight in the fly wheel and bed plate, and that the foundation be more than usually substantial.

One of the most important features to be observed, in order to maintain perfect regulation, is to place the engine in the hands of a competent engineer, who is capable of adjusting and keeping the engine in good running order; a good engine, or piece of machinery, placed in the hands of an incompetent person will never give good service or economical results, and no doubt a large number of cases where engines do not give good service, the expense of maintenance high, and perhaps a large number of the frequent casualties, are attributable to incompetent, careless or negligent engineers.

The matter of economy has been exhaustively discussed from a scientific standpoint in the various periodicals, as well as before the learned societies, and your committee feels inadequate to the task of presenting a report that will not be a repetition of the records on the subject. The committee will, therefore, not undertake to deal with the subject in an elaborate and scientific manner, but will endeavor to give a few practical hints that will be of interest to the Association.

The economy of an engine is dependent to a great extent on the other parts of the power plant, and it will therefore be proper to discuss the matter in all of its phases, even though it may be a slight digression from the subject proper, as economy is the most important factor in the operation of a power plant.

In order to obtain the highest economy in the operation of an engine, it is necessary to have the engine properly adjusted to its load. It is a fixed principle that the highest engine efficiency results in working the engine constantly at its maximum rated capacity; underloading or overloading are each, therefore, undesirable, though the compound condensing engines of the larges stations will stand underloading better than the simple high-speed engines, and both classes of engines will stand underloading better than overloading; there should then be ample power both in boilers and engines to obviate excessive overloading as well as to provide for contingent breakdowns or needed repairs. Whatever the style or type of engine adopted, it should be kept scrupulously in the best possible working condition. The packing should be kept intact, valves free of leaks, cylinder perfectly smooth and true in diameter, so that there will be no loss of live steam. The cylinders and bearings should be kept well lubricated, and one of the most important factors is to have the steam enter the engine at a steady pressure at all times, as good service cannot be obtained when a steady steam pressure is not maintained. Careful attention should be given to the setting of the valves so that the cut-off will be the same at both ends of the cylinder. The engines should be set in the closest proximity to the boiler so as to require the least amount of steam pipe, as the longer the steam pipe the greater is the loss by condensation. The steam pipe should be covered with one of the best non-conducting materials, of which there are several on the market, so as to reduce to the minimum the loss by conduction, radiation and consequent condensation. Flexible joints should be used to prevent leaks at the joints from expansion and contraction. It should be borne in mind that wherever there is a leak of steam there is a loss of dollars and cents.

We are so accustomed to consider the reciprocating engine as the only steam motor within our reach that it is not surprising that a new form of steam motor should have quietly been developed without our notice. The committee refers to the steam turbine, one form of which, the Parsons steam turbine, has recently been subjected to rigorous and searching trials and tests by Prof. A. D. Kennedy, of London, England, who has developed power at the rate of $20\frac{3}{10}$ pounds of water per electrical horse power per hour in a turbine using steam at 97 pounds per square inch and making 4,600 revolutions per minute, the turbine having a capacity of about 165 horse power. The small size of this motor, absence of reciprocal motion and consequent independence of heavy foundation; high speed of rotation and consequent availability for gearing direct to generator; simplicity of construction and consequent low cost, and its very high efficiency as a motor, all tend to make this a strong rival to the reciprocating engine as a steam motor for electric power and light stations.

The next point to consider is the boiler room, where the steam is generated. Engines may be of the very best type, and, together with the steam pipe, may be in perfect condition, but unless the boiler room receives the proper attention there will be dollars lost where cents are saved in the engine room. The design and proper construction of the boiler plant are quite as essential to economy as is the case with the engine. The boiler plant should have ample capacity, as there are few cases when the draft and setting are so excellent as to allow heavy forcing without a serious loss of economy. A raising of the evaporation from $6\frac{1}{2}$ to 7 pounds of water per pound of coal represents the saving of about seven per cent. of the coal bill, which would warrant the incurrence of an expenditure for improvements equal to one whole year's coal bill. The boilers should be equipped with good boiler cleaners, and should be inspected regularly and kept free of scale; the flues should be kept clean and boiler walls intact. With the boilers in proper condition, and with proper draft, the very best results should be obtained, but in order to do this the boiler room must be in charge of a competent man.

Fuel is one of the largest items of expense attached to a power house, and the waste of fuel by incompetent firemen is one of the greatest leaks attached to the operating expenses; it is a safe proposition to state that an incompetent fireman will waste enough fuel in a year to assist very materially in paying a dividend. Simply the act of pitching a shovel of coal does not qualify a man as a fireman, it requires skill and intelligence. There is a natural disposition among the laboring classes to endeavor to do their work with the least amount of labor, and as a rule the fireman will fill his furnace half full of coal at one time, give it a stir with a poker, and then sit down and rest until time to fill it up again, instead of firing frequently, maintaining a light fire, and scattering each shovel of coal evenly over the grate bars, by which the maximum amount of heat can be obtained from the least amount of coal.

The use of oil as fuel in place of coal is a live question with power and light station engineers and managers. Probably the most complete evidence of this kind comes from a recent and exhaustive test of the power plant of the Twin City Rapid Transit Company of Minneapolis and St. Paul, Minn., made by Messrs. Wm. A. Pike, of Minneapolis, and T. W. Hugo, of Duluth, Wis., on the comparative value of the two fuels, coal and oil. This test showed that with ordinary Lima oil weighing $6\frac{8}{10}$ pounds per gallon, and costing $2\frac{1}{4}$ cents per gallon, and coal that gave an evaporation of $7\frac{1}{2}$ pounds of water per pound of coal, the two fuels were equally economical when the price of coal was $3.85 per ton of 2,000 pounds. With the same coal at $2 per ton the coal was 37 per cent. more economical, and with the coal at $4.85 per ton the coal was 20 per cent. more expensive than the oil.

---

* Abstract of Committee Report read before the American Street Railway Association.

The loss of power between the engine and switchboard terminals is from 15 to 25 per cent., which is attributable to the inefficiency of dynamos, and also to the friction of countershafts, belts, idlers and attachments, which are simply power consumers, representing a waste of power without any resultant benefit. Besides the loss of power, the expense of maintaining the various arrangements for the transmission of power is quite considerable. This waste of power can be overcome by connecting the generator direct to the shaft of the engine. While machinery of this class is more expensive than the other because it demands a slow speed for the generator, necessarily increasing its size, the saving in power and maintenance of the machinery of transmission will be sufficient to compensate for the slightly reduced dynamo efficiency, due to slower rotation, and will warrant the recommendation of the direct driven equipment for moderate or large sized plants. The direct coupling of engine and generator gives also an important advantage, particularly in the large stations in crowded cities, by the considerable saving in floor space.

The committee look with favor upon compound engines for street railway work, especially so with engines having ranges of cut-off wide enough to keep the low pressure cylinders from ever expanding below atmosphere. When this is the case, there is no doubt that the compound engine is very economical, as it carries the expansion of steam to a greater limit. Where it is possible to condense in connection with the compound engine, there is not the slightest question as to economy. In fact, where condensing is possible, there is no reason why the expansion should not be carried to a further limit.

When electric traction was first introduced for street railways, engine builders were not cognizant of the actual requirements for this kind of service; they did not anticipate fully the extraordinary variation of load and the liability of a short circuit, which so severely test the strength of an engine. They proceeded to build engines from theoretical plans and specifications which have proved by actual practice to be entirely inadequate for this class of work. Engine builders, however, are endeavoring to overcome mistakes which were made at the outset, by strengthening and making all of the parts more durable and to make such improvements as will meet all the demands for this extraordinary class of work.

DIVISION OF POWER INTO UNITS.

When electricity was first introduced as a motive power for street railway transportation the largest type of generators were small units as compared with those manufactured at the present time, and, as a rule, high-speed engines, from one hundred to two hundred horse power, belted direct to the generator, were in most cases adopted without regard to the size of the plant. Local surroundings and conditions will, to some extent, govern the division of power into units, but, as a rule, the following principle will be safe to follow: The size of the proper unit of subdivision should be such as to give the required relay or reserve above the maximum power adopted. This will apply equally to boilers, engines and dynamos. The accompanying table will serve to show approximately the proper proportion.

Maximum H. P. Required to Operate Road.	Number of Engines Required.	H. P. of each Engine.
200	2	200
400	3	200
600	3	300
1,000	3	500
1,500	4	500
2,000	4	750

It will be observed from this table that enough engines are provided to furnish the maximum horse power required to operate a road and have a surplus of one engine. This is very essential, as it enables the engineer to keep his engines in perfect adjustment and repair, having at all times an extra engine to work on, or, in case of a breakdown, the extra engine is ready to take the place of the disabled one.

In selecting a type of engine, the size of the installation must largely govern, as well as local conditions, such as water supply and price of fuel, though some consideration may be given to opportunities for station room and arrangement. For small plants to run ten or fifteen cars, simple high speed engines belted direct to generators are unquestionably the proper choice. For twenty to fifty car plants, compound engines, with condensing apparatus where it is possible, with tandem compound engines for the smaller plants and cross compound engines for the larger ones, geared direct to generator, will probably be found most economical, while for the larger systems compound or triple expansion condensing engines, using steam at a high initial pressure and either driving a countershaft or coupled direct to generator, whichever the conditions of the case will warrant, will be found a proper selection. In every case, except for small plants, where engines are belted direct to generator, the vertical type of engine is recommended.

In conclusion, the committee desire to impress the importance of keeping the steam plant as near as possible to the conditions that exist when the engines are installed and being run under the supervision of the mechanical engineer who installed the plant. This, perhaps, is of as much or more economic importance as the design of the engine, as the plant is then run by the expert in charge with a view to attain the highest degree of efficiency and economy.

Respectfully submitted.

E. G. Connette, *Chairman of Committee.*

Heavy Gradient Compensator.

One of the most ingenious contrivances for assisting tramcars up and down a short length of stiff gradient is described in the *Engineering Review* for September. The plant has been in successful operation for some time at Seattle, Washington. For a distance of 1,000 feet there is a gradient varying from 11 to 16 per cent. Two counterbalance weights aggregating six tons run on rails laid in a conduit beneath the track. These weights exactly balance an empty car, and are attached to wire ropes running over pulleys. At the top of the gradient on its way down the car picks up the rope and in descending hauls the weights up, thus checking its own speed, so that the car brakes will hold the load without difficulty. At the foot of the gradient the conductor disengages the rope by means of a hand-lever. Going up, the connection is made automatically and disengaged in a similar manner. A gradient of 20 per cent. may be readily overcome by means of this simple and admirable expedient. It will be evident that since the action is cyclical the only loss of power is that due to the small friction of the gear and tackle, while the only condition necessary to continuous working is that cars going up the gradient shall alternate with those coming down. In a horse traction system such a device means humanity; in a system of electric traction it means smaller motors per ton of rolling stock and a greater annual saving of energy which would otherwise be spent in raising cars up hill or in brake-power on the down trip.

BOOK REVIEWS.

Drum Armatures and Commutators. By F. Marten Weymouth. The Electrician Printing and Publishing Company, Salisbury Court, Fleet Street, London, Eng. 273 pp. 152 illustrations.

This work treats in an elementary manner the subject of drum winding, and describes the principal methods of winding in use on armatures of this type. Commutators are also treated in the same general manner, which is essentially descriptive.

The first nine chapters deal with the various styles of drum windings in use in different types of machines, and the construction of these armatures. The four following chapters are devoted to the description and construction of various commutators, and the remaining chapters treat of armature reactions as affecting sparking at the commutator.

The scope of this work is limited to the discussion of the general principles of construction and to descriptions of drum armatures, and avoids mathematical treatment as far as possible, as well as all reference to the calculation of the windings and capacities of armatures. For this reason the book is necessarily elementary and is adapted to the instruction of the beginner rather than to the use of the practical designer of electrical machinery.

Within the range covered by this work the information is complete and accurate. The general principles laid down for the design of armatures and the best methods of construction, as well as the precautions to be observed in the matter of insulation, are all carefully explained at considerable length and in language intelligible to the non-technical reader.

The Book of the Fair. By Hubert H. Bancroft. The Bancroft Company, Publishers, Chicago, Ill. Twenty-five parts, 40 pp. each. Price $1.00 a part.

We have before us Part IV of this serial which is being issued at the rate of about two parts monthly. The object of this work is to present in print the Columbian Exposition entire, and the name of its well known author is a guarantee of its excellence.

Too much cannot be said of the artistic features of this work. The illustrations, which are well chosen, are profuse and handsomely executed. The work is printed on heavy enameled paper, with imperial folio pages 12 x 16, and the typography is unsurpassed. When completed, the volume will form an interesting as well as an elegant souvenir of the Exposition. Rhude, Thomas & Company, 24 Park Place, New York, are the sole agents for the work this section.

Personal.

Mr. Charles Wirt, late electrical engineer of the Ansonia Electric Company, has opened an office as consulting engineer at 56 Fifth avenue, Chicago.

Mr. W. H. McKinlock, president of the Metropolitan Electric Company, who has been in the East for a couple of weeks, has returned to Chicago.

Mr. B. J. Arnold, who was connected with the Chicago office of the General Electric Company for a long period, has established himself as a consulting engineer, with offices in the Rookery.

Mr. H. W. Weller, who has a wide reputation in the trade through his connection with the Sprague and Edison Companies, is now general manager of the United Columbian Electric Company, 280 Broadway, New York.

The Ansonia Electric Company's Affairs.

Application was made in the Superior Court at New Haven two weeks ago for the removal of John B. Wallace as trustee of the insolvent Electrical Supply Company of Ansonia, on the ground that Mr. Wallace owes the concern more than $100,000. The court was also asked to order the books of Wallace & Sons, of Ansonia, inspected by an expert. The petition states that John B. Wallace is indebted to the firm from $25,000 to $100,000.

New President of the West End Railway Company, Boston.

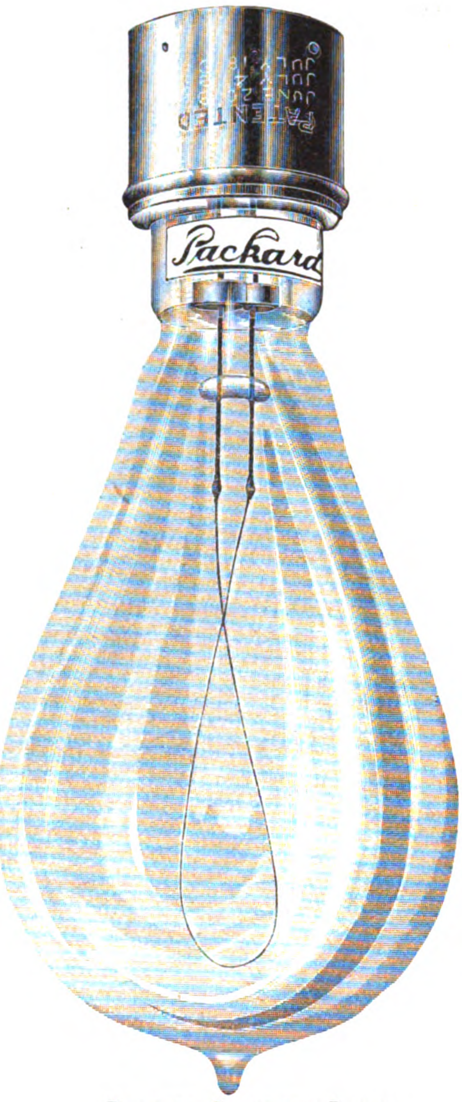
To the surprise of many people the announcement appeared in the Boston morning papers on Thursday that Mr. Samuel Little had been appointed president of the above road in succession Mr. H. M. Whitney, who resigned a few weeks ago.

Since Mr. Whitney's retirement several names had been mentioned as those of his prospective successor. These names included that of Mr. C. A. Coffin, president of the General Electric Company, and Mr. Nathan Matthews, Mayor of Boston. Both have shown much interest in street railway concerns and were thought very eligible for the office. It was stated only a few days ago that no successor to Mr. Whitney would be appointed until the annual meeting in November, but the directors decided otherwise, and on Wednesday one of their own number was chosen.

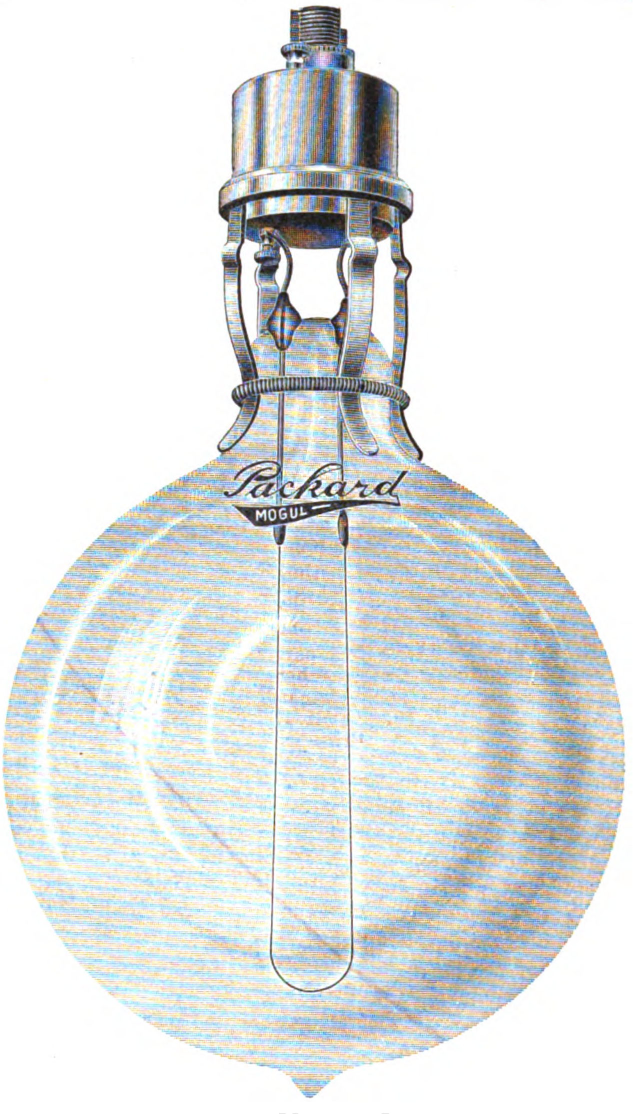
Mr. Little has been identified with the road since its inception. He was one of the original organizers of the Highland Street Railway in 1872 and its treasurer until its consolidation with the Middlesex Company. From the time when all the Boston roads were consolidated and became the West End system, Mr. Little has been a director of the company.

The new president is one of the best known men of affairs in mercantile Boston, and has for years taken a prominent and active part in the management of several large concerns. At the present time he is president of the E. T. Howard Watch and Clock Company, the National Rockland Bank, the Bay State Gas Company and the Boston Lead Manufacturing Company. He is also a director of the Boston, Dorchester and South Boston Gas Light Company and a trustee of the Roxbury Institution for Savings. For more than twenty years he took an active part in public life, having been a member of the State Legislature and of the Boston Board of Aldermen, as well as one of the Board of Directors of Public Institutions of Boston. Mr. Little is a prominent Mason, having filled several important positions in that ancient order, and stands high in the regard of all who know him. In looks, training and genealogy, he is a thorough New England man, having been born, August 15, 1827, in Hingham, Mass., where his ancestors settled after they arrived from Hingham, England, in 1637.

The new president is thoroughly well posted in railway matters as the outcome of a long and active experience, and while he has not as yet outlined the policy he will pursue, his long and close connection and endorsement of Mr. Whitney's policy warrants the belief that the same policy will be pursued under the new president.



Packard Standard Lamp.



Packard "Mogul" Lamp.

PACKARD LAMPS.

The Factory at Warren Running on Full Time.

The "Mogul" Lamp to be Made in Sizes up to 1,000 Candle Power.

The Packard "Mogul" lamp illustrated above is something different from any other lamp heretofore attempted commercially in the United States, and at present they are being manufactured in sizes of 200, 300 and 500 candle power, while other sizes up to 1,000 candle power are in preparation. Special quality of carbons of very low resistance is used in the manufacture of these lamps, and combined with a treatment with gas it produces a lamp of very high efficiency and one that maintains its candle power nearly constant during its normal life.

An efficiency of two and one-half watts per candle power may be attained, and consequently with the same dynamo and engine power nearly double the light of ordinary lamps can be obtained with the Packard Moguls. As compared with small incandescent lamps or with arc lamps in opal globes they give far more light for the same watt expenditure and are absolutely steady. The light never falls momentarily in brightness as does the arc lamp, and its color is much pleasanter and casts no objectionable shadows; it gives no hissing noise and requires no attention from the time it is first installed until the lamp gives out.

Packard Moguls are made in two classes, A (high efficiency) and B (longer duration), but they can be made especially for any efficiency. When they are run at the usual efficiency of the ordinary incandescent lamp their life exceeds that of the latter, but for lighting large spaces it is found more economical to run them at the higher standard.

As their cost is small compared to a group of small incandescent lamps, the extra light gained will on the average pay for the cost of the renewal of the lamp after 150 hours of life.

A special porcelain socket and shade must be used with these lamps. These are permanently attached to the fixture or suspending cord and do not have to be renewed with the lamp.

Packard Moguls are especially adapted for lighting stores, large halls, exhibitions, reception rooms, etc., and in short, wherever a large, steady and efficient light is required.

Packard Standard Lamps.

The Packard factory is now in full operation turning out their new style 6 to 50 candle power lamps of the pattern illustrated. These lamps are protected by about twenty patents besides a number of applications for additional patents.

The neck of the lamp is closed with cement and mica, and iron is used in the in-leading wires, which are not sealed into glass. By this method of manufacture they sacrifice none of the merits of the old style lamp, but all of the good qualities are retained and several new ones added which are genuine improvements.

The Niagara Power House.

The Cataract Construction Company at a recent meeting closed a contract with Stewart & Company, of St. Louis, for the construction of the immense electrical power house at the Falls, and work will be commenced immediately. The contracts for the electrical apparatus, dynamos and other large machinery were discussed at the same meeting, but no awards made.

Current Items.

The tallest building in Stockholm, says the London *Daily News*, is the huge iron latticework tower of the central telephone depot. Myriads of wires run from it, darkening the air. Every one in Sweden uses the telephone, and uses it, moreover, very much. A writer in *The Cornhill*, who has been sojourning in a boarding house in the Swedish capital, declares that the most significant feature in the routine of the establishment was its never-ending telephone babble. When he awoke in the morning it was to hear the jingle of the bells in the corridor outside his room and the iteration of the word "hvad?" (what?). One morning he asked the landlord, who was at the machine, what it all meant. His wife, he replied, was buying some stores, and was telling him about them and their prices, and he on his part was shouting back to tell her in which particulars the prices seemed reasonable and in which unreasonable. Another day the writer's landlord went for a sleigh drive into the country. When he had gone two hours the telephone began to be annoying, and his wife stayed at it for a long time, crying, "oh!" and "ah!" and "yes" and "no." "It is monsieur," explained a young lady who happened to be standing by. "He is resting for dinner at ——, and is informing madame about the incidents of his excursion and the details of the meal that is being prepared for him."

A suggestion having been made of telephonic connection between churches and the houses of lazy or infirm parishioners, in order to supplement the attendance at services, the Rev. Arthur Ritchie is quoted as favoring the scheme, while a number of other clergymen oppose it on one ground or another, principally because the personal influence or individuality of the preacher would be lost. A Roman Catholic clergyman asks: "Can a person receive the full benefit of the presence in the body of the Divine Presence at a mass through telephone? Oh, no; it is necessary for a personal attendance at church and for the eye to see as well as the ear to hear the priest when he celebrates mass, if a person is to receive the full benefit."

To meet the requirements of the numerous large establishments engaged in the manufacture of ready-made garments, in which many hundreds of yards of fabrics of various kinds are cut to pattern every day to be fashioned into articles of wearing apparel, a new electric cloth cutter has been devised. These machines are said to be used in large numbers in New York, Boston, Buffalo, Rochester, Chicago and elsewhere. One machine, it is affirmed, will do the work of eight men. As an example of its serviceability, the statement is vouched for that in a certain New York clothing manufactory one machine is doing the work of cutting 1,000 pairs of trousers per week of five and a half days.

Carl Peterson, a native of Sweden, now residing in Brooklyn, N. Y., is the inventor of a safety trolley device, for the manufacture of which a company has been formed in Brooklyn, with Mr. Peterson as president. He claims that it will do away with all danger of falling trolley wires. The invention consists of a number of brackets, one of which is fastened on the support of the main trolley wire. The brackets are fastened together by a clamp. When a wire falls, or even sags, the clamp opens and the current is stopped. At the same time the system can be operated so that there will be no blockades. The road is only affected between the two supports where the break occurs. The cars can be run up to the break, shifted across the intervening space of about 100 feet, and continue trips.

The question of long distance submarine telephone cables is one which has of late attracted much attention. The idea that a merchant in New York could converse directly with his correspondent in London is a captivating one, especially as questions could be asked on both sides and explanations given to a degree not possible in practice with telegraphy. That the time will shortly arrive when this will be done is the opinion of some of the foremost electrical engineers of the day. An authority of such weight as W. H. Preece, the electrician-in-chief of the English postal telegraph service, has already expressed his belief in its feasibility, and Prof. Silvanus Thompson now concedes that ocean telephony is possible. He says: "The means of attaining it are within our grasp. Compensated cables of the new type are entirely practicable. It may be needful to begin with some shorter line than an Atlantic cable in order to gain experience. But an Atlantic cable constructed on the new plan will not cost much more when laid than one of the old type, and whether or not it is successful in conveying telephonic speech it will certainly transmit telegraphic messages at a greatly accelerated speed of signaling. If one Atlantic cable can be constructed to do the work now requiring eight cables that cable will be constructed. Acceleration of ocean telegraphic service is in itself a desirable step in advance, but the advance will not be complete until telephonic speech is transmitted also from shore to shore."

L'Electricien, Paris, gives the following pedigree of a word which has attained importance in electrical phraseology: Most persons who use the word "trolley" probably do not know the origin of this term, or why this name was given to that apparatus by which the electricity is conveyed from an aerial wire. Twenty years ago the word was used to designate "a form of truck which can be tilted, for carrying railroad material or the like." This is the only definition of the word in Webster's Dictionary of the edition of 1848. In the edition of 1892 of the same work, three other definitions are added. 1. "A narrow cart that is pushed by hand or drawn by an animal." It is noted that this meaning of the word is in use in England, not in the United States. 2. "A truck from which the load is suspended on some kinds of cranes." This meaning is technical, according to Webster, and employed only in speaking of machinery. 3. "(Electric Railway.) A truck which travels along the fixed conductors and forms a means of connection between them and a railway car." It is easy to see how the primitive form of the electric trolley, which travels upon the wires, came to receive its name from its resemblance to other types of trolley; and the name, having been immediately given to this primitive form, was naturally retained when the method of connection was changed from a little truck moving on a wire to a mast having at its end a wheel pressing on the lower surface of the wire.

The latest application of electricity in marine work is to a deep sea fishing boat. A vessel has been fully equipped in England with facilities for utilizing electricity, not only for propulsion but for hauling nets and every other purpose where power is required in the fishing industry.

General News.

What is Going on in the Electrical World.

San Francisco.—The Baden extension of the San Francisco and San Mateo Railway Company is completed.

Indianapolis.—It has been decided to convert the street railway that runs out Kentucky avenue into an electric line.

Plainfield, N. J.—The Plainfield Electric Street Railway Company is building an extension of its line to reach New Market.

Wilmington, Del.—The track of the New Castle and Wilmington Electric Railway will probably be laid this fall, and the wiring and other work be done next spring.

Westbrook, Me.—The Westbrook Electric Light Company has strung wires for the incandescent circuit to Deering and expect to have that city lighted by the last of the present week.

Grand Haven, Mich.—The electric light plant here has been sold by the Greenwich, N. Y. owners to Andrew J. Ernlaw and Geo. W. Miller, of Grand Haven. The plant is valued at $20,000.

Emporia, Kan.—At a late meeting of the city council resolutions were passed looking to the purchasing of an electric plant, and the committee on gas and electric lights was instructed to take such steps as were necessary.

New York.—The east and west driveways in Central Park are to be lighted by incandescent electric lights, served probably from underground conduits, as the park commissioners have so recommended to the Board of Electrical Control.

Hagerstown, Md.—The engineers of the South Mountain Electric Railway, between Keedysville and Boonsboro', have resurveyed the line, making some corrections and shortening the route. The road must be finished in three months.

Ottawa, Can.—An electric dynamo has been placed on a special car at the Canada Atlantic Railway workshops for the purpose of furnishing electric light to the workmen on the Parry Sound road above Arnprior, where the work of laying the steel is to be pushed forward night and day until Renfrew is reached.

Warwick, N. Y.—The Greenwood Lake Railroad Company is considering the scheme of building a trolley line from Greenwood Lake to Warwick, with a view to attracting travel to the railroad. A fine water power at Hewitt's station will, it is claimed, generate all the electricity needed for the operation of the road.

Toronto, Can.—The present year will see all the street car lines within the city converted to the electric system, and next year will likely witness a big development of suburban lines, which will either work in a close alliance with the city system or become part of it. This development will probably cater not so much to the passenger as to the freight traffic.

Chicago.—The Chicago City Railway Company has asked permission of the council to apply the overhead trolley system to all its horse lines.—The Board of Underwriters has decided that hereafter the introduction of electric light into a building, or electric power, or any change in electrical connections, must be approved first by the insurance companies, or the policy will be vitiated.

Sioux City, Iowa.—The creditors of the Sioux City Street Railway Company, which is being operated by a receiver, are preparing a plan for the reorganization of the company. It owns forty miles of electric road, the chief system of the city, and the appointment of a receiver was necessitated by its inability to pay interest on the $1,500,000 of bonds it has out. A meeting of bondholders and other creditors will be held soon to adopt a plan.

Leavenworth, Kan.—Newman Erb, L. M. Erb and M. Summerfield have registered the transfer by the Leavenworth Suburban Street Railway Company of its real estate franchises, cars, equipments, machinery, etc., to the Leavenworth Electric Railway Company, the consideration being $193,000. Electricity will replace the present motive power (dummy and horses) on the greater portion of the line if Mr. Erb's application to do so be granted by council.

Baltimore, Md.—The Southern Electric Company, which made a voluntary assignment in July last because of temporary embarrassment arising from inability to make collections during the financial depression, is about to resume business under its former management. At a meeting of the creditors in New York, the Roebling's Sons Company of Trenton, N. J., the Safety Insulated and Wire Company, the Interior Conduit and Insulation Company, the Okonite Company Limited, and the Western Electric Company of New York, all creditors, were named as a committee to confer with the Southern Electric Company as to the details for the resumption of business.

Tacoma, Wash.—The new Tacoma-Spokane long distance telephone, the second longest line of the kind in the world, has been completed and is now in operation. The line is 600 miles long and extends from Tacoma to Portland, via Tenino, Centralia, Kalama and Vancouver; thence up the Columbia River, across to Colfax and Garfield, and thence along the line of the Spokane and Palouse branch of the Northern Pacific to Spokane. From Portland there is a branch west to Forest Grove, thence south to Independence, Albany and Corvallis, with another branch line to Oregon City and Salem. From Tacoma there is a branch line to Olympia and Hoquiam, another to Orting and another to Seattle and Everett.

Boston Notes.

The Pittsfield, Mass., Electric Railway Company has recently held its annual meeting, at which a very satisfactory report was submitted. The treasurer's report showed that the company had enjoyed a very prosperous year. A new track had been laid nearly the entire length of the road at a cost of $17,000.

The Edison Electric Illuminating Company of Boston has declared a quarterly dividend of 2 per cent. payable November 1. This company is now doing an enormous business in every part of the city, and just as soon as the present financial depression ceases they expect to still further largely increase their business.

Mr. George A. Marden, who is Treasurer for the State of Massachusetts, has just returned from the World's Fair, and in speaking of the great Exposition he said to an acquaintance: "The thing about the World's Fair that struck me most forcibly is the important part that electricity plays in making it the perfect Exposition it undoubtedly is. Without electricity the Fair would be a totally different thing. Eliminate the illumination of the Court of Honor and the Wooded Island, take away the electric railway and the electric launches, close the Electricity Building and remove the electric lights from the grounds and buildings, and one-third of the Fair has disappeared. If we have made this Exposition immeasurably greater than the one of 1876, electricity is greatly to be thanked for it."

The New England Telephone and Telegraph Company has declared a dividend of 75 cents per share payable November 15.

The big new power station erected by the Union Railway Company, Providence, R. I., is nearing completion, and one of the powerful engines was started up for the first time on Thursday last. The plant that is being installed consists of 3 Greene compound engines of 750 H. P. each, run by the batteries of 6 Babcock & Wilson boilers of 1,500 H. P. aggregate capacity. These engines are belted directly to the electric generators of 500 K. W. each, built by the General Electric Company. There are two more engines contracted for of 1,100 H. P. each, which will also be coupled directly to generators. The interior of the engine room is 170 x 72 feet, and the boiler room 104 x 72 feet. The company will use its own electric current on the street cars from November 1.

Col. John T. Wheelwright, a well known Boston lawyer and novelist of repute, has been appointed a member of the State Board of Gas and Electric Commissioners to take the place of Commissioner McDonald, resigned. Col. Wheelwright is noted for his ability and fearlessness, and his accession to the Board is considered to promise advantage to the community.

The Framingham Union Street Railway Company is discussing the question of electricity as a substitute for horse power on its system.

The Quincy and Boston Electric Street Railway Company has declared a 6 per cent. dividend and carried $3,000 to its reserved fund. This company is one of the most prosperous in New England.

It was hoped by the manipulators on the inside that the jumps of 7 or 8 points in General Electric stock which occurred Wednesday and following days, after receipt of repeal news from Washington would tend to restore confidence in the Trust, but it didn't. Conservative men are as shy of it as ever, and it is impossible to find a man who believes anything but that the Trust is nearing its fate—collapse and reorganization. It is equally difficult to get an intelligent expression of opinion as to how matters are working on the inside, but an evening or two ago a gentleman standing very, very near to the president was frank enough to admit that his own opinion and that of others connected with the company both as stockholders and officials was that the only hope of salvation is in the appointment of a receiver, and that the sooner such a step is taken the better for every one interested.

A petition signed by 8,000 prominent citizens came up for hearing before the Board of Aldermen Wednesday afternoon, the petition praying for a reduction of street railway tracks and cars on Washington and Tremont streets. The hearing was a lively one, the petitioners being ably represented by Messrs. Arthur T. Lyman and T. L. Gargan, Mr. H. D. Hyde being in attendance as counsel for the West End Company. For the petitioners it was shown that they represented $180,000,000 of property, and claimed to voice the sentiments of most of the best people in Boston. Mr. Lyman stated that as many as 400 cars per hour passed along parts of Tremont street, while at the Park Street Church over 100 cars were shifted in the hour to the obstruction of the general traffic and with great danger to the crowds of foot passengers in that district. It was urged that only a single track should be allowed along the northern or busy downtown sections of Tremont and Washington streets, and that a circuit should be formed whereby all cars should run round in one direction. It was urged that the public could be properly accommodated under the suggested system, while the inconvenience and dangers would be minimized. Both prominent ladies and gentlemen supported the petition, and warmly urged prompt and decisive action on the part of the aldermen. Mr. Lyman in alluding to the number of accidents that were always occurring, said: "Wonderful street railroading, but a disgrace to the city! It is a magnificent nuisance!" The hearing will be continued Friday evening.

The West End Railway Company's estimated earnings for twelve months ending September 30 were about $385,000 larger than last year, and net about $200,000 larger. Earnings are now about the same as last year. The customary increase of $1,000 per day has not been realized for two or three months.

COMMERCIAL PARAGRAPHS.

The Newton Rubber Works, whose chief offices are in the John Hancock Building, Boston, and factories at Newton, Upper Falls, Mass., is a wealthy firm possessing almost unlimited facilities for the manufacture of rubber goods, including car springs, buffers, rubber-covered rolls, and other devices for use on street railways. The company makes a specialty of storage battery cells, which are now in use everywhere. These cells are of hard rubber, moulded to shape and size as required, and occupy a leading place in storage battery work. They have been on the market for some time, and give splendid satisfaction, the company having received many repeat orders. They are at present busy on some good contracts, and the outlook for business is most promising. Recently they have had to largely increase their facilities, and under the careful yet enterprising care of Mr. Edwin R. Rand, general manager, the company is very prosperous.

The Stirling Company has closed contracts since the 1st of October, 1893, with the following firms for their well-known and efficient boilers: L. A. Riley & Company, Centralia, Pa., 250 H. P.; Simpson & Watkins, Scranton, Pa., 300 H. P.; J. I. Case Threshing Machine Company, Racine, Wis., 300 H. P.; Adriance, Platt & Company, Poughkeepsie, N. Y., 250 H. P.; Midland Steel Company, Muncie, Ind., 400 H. P. This company is to be congratulated for the fine reputation it is making with its specialty, which reputation has just been still further increased by receiving the very highest award given for boilers at the World's Fair. As will be remembered, the Stirling Company had a hard legal battle to fight with competitors before they were admitted to the Fair, but they won their fight, and have captured the highest honors, and now a genuine boom has started up for Stirling Water Tube Safety Boilers.

H. Ward Leonard & Company have placed their name prominently before their friends by distributing an advertising blotter containing a long list of the most important plants installed by them during the past year.

INCORPORATIONS.

The Carbondale and Dundaff Street Railway Company, Scranton, Pa.—to construct and operate an electric railway. Capital stock, $30.000. Promoters: Michael Moran, Carbondale, Pa.; Jos. O'Brien, Jno. P. Kelly, Scranton, Pa.

The Ongley Company, Hoboken, N. J.—to purchase, manufacture and sell electrical and other devices and appliances, patented or otherwise. Capital stock, $25,000. Promoters: G. M. Keasbey, Newark, N. J.; C. E. Ongley, G. B. Hopkins, W. P. Dixon, Jr., W. Miller, G. J. Schoeffel, New York City.

The Forest City Electric Railway Company, Scranton, Pa.—to construct and operate an electric railway. Capital stock, $30,000. Promoters Michael Moran, Carbondale, Pa.; Jos. O'Brien, Jno. P. Kelly, Scranton, Pa.

The Green Electric Signal Company, Kittanning, Pa.—to manufacture and sell articles of commerce made from wood or metal. Capital stock, $50,000. Promoters: M. D. Wayman, Ford City, Pa.; Ira L. Green, G. M. Fox, Kittanning, Pa.

The South Mountain Electric Railway and Power Company has been incorporated at Hagerstown, Md., by George W. Jacobs, Jr., of Philadelphia; Theodore E. Bowne, of New York; Edgar L. Miller, Elmer J. Smith, of Frederick; Charles J. C. E. Shafer and George A. Davis, of Boonsboro. The company will construct and operate twelve miles of electric railway in Washington County, three miles of which will be between Boonsboro' and Keedysville, Md. They will also light the towns of Boonsboro' and Keedysville.

The West Baltimore Passenger Railway Company, incorporated at Baltimore, Md., on the 18th inst., intends to build a suburban electric line through Mount Winans and Camden Junction to the Relay and finally to Ellicott City. Connection with Baltimore lines will be made probably through the Columbia avenue line of the City and Suburban Company. The directors of the proposed road are Wallace Stebbens and Harry O. Stebbens, of Relay: W. H. O'Connell and Henry W. Bennett, of Baltimore, and Barton W. Fenton, of Findlay, Ohio. The capital stock is $100,000.

The Tacoma Gas and Electric Company. Tacoma, Wash.—to erect and operate gas and electric light and power works and sell and dispose of their products. Capital stock, $500,000. Promoters: Wm. H. Elliott, Edmund Rice, Wm. A. Rice, Tacoma.

The Mather Electric Company has filed a certificate with the Connecticut Secretary of State certifying to the issue of preferred stock to the amount of $81,000 and the reduction of capital stock from $200,000 to $120,000.

The Suburban Street Railway Company, Harrisburg, Pa.—to construct and operate an electric railway. Capital stock, $5,000. Promoters: W. H. Seibert, Steelton, Pa.; E. K. Meyers, C. L. Brinser, Harrisburg, Pa.

The Jonesville Electric Light and Power Company, Jonesville, Mich.—to furnish electric light and power to the village of Jonesville. Capital stock, $15,000. Promoters: Geo. F. Avis, Hudson, Mich.; Geo. S. Pomeroy, Enos A. Pomeroy, Victor Hawkins, Jonesville, Mich.

The Gladstone Electric Lighting and Power Company, Gladstone, Mich.—to manufacture and sell electricity for light, power or otherwise. Capital stock, $20,000. Promoters: Jno. W. Kendrick, Jno. Wood, Minneapolis, Minn.; Edwin S. Tice, Gladstone, Mich.

The Gibbs Electric Company of Milwaukee has filed notice increasing its capital from $2,000 to $10,000.

The Connecticut Dynamo and Motor Company, Hartford, Conn.—to execute electrical and mechanical engineering and do all things incidental to said business. Capital stock, $6,000. Promoters: Roscoe W. Ney, Robert E. Dunston, Hartford, Conn.; Donald W. Durand, Middletown, Conn.

The Jamaica Electric Light Company, Jamaica, N. Y.—to manufacture and use electricity for light, heat and power. Capital stock, $15,000. Promoters: Geo. R. Cullingworth, Mt. Vernon, N.Y.; Wm. S. Williamson, Jamaica, N. Y.; Alonzo B. Pettit, Jamaica, N. Y.

The Bryan, Marsh Company, New York City—to manufacture and sell electric batteries, lamps, etc. Capital stock, $40,000. Promoters: Converse D. Marsh, 202 W. 74th street; Thos. C. Hughes, 206 W. 52d street, New York City.

The Natchez Light, Power and Transit Company, Natchez, Miss.—to do a general light, power and transit business. Capital stock, $200,000. Promoters: Maurice Moses and Abraham Moses.

People's Power Company, Rock Island, Ill.—to manufacture and furnish light, heat and power to citizens of Moline and Rock Island. Capital stock, $300,000. Incorporators: Thomas B. Davis, Samuel S. Davis and Charles V. Nason.

Simpson Electrical Supply Company, Chicago, Ill. Capital stock, $12.000. Incorporators: George A. Gloeman, Henry R. Pebbles and Thomas Fahey.

Electric Car Ventilating Company, Portland, Me.—to manufacture and deal in ventilating apparatus and machinery of all kinds. Capital stock, $500,000. Promoters: Wm. Y. Ober, Lynn, Mass.; L. B. Haskell, F. W. Homans, Gloucester, Mass.

Inman Brothers Construction Company, Jersey City, N. J.—to construct, buy and sell water works, gas works, electric light works, etc. Capital stock, $75,000. Promoters: G. B. Inman, W. F. Inman, A. C. G. Williams-Foote, all of 136 Liberty street, New York City.

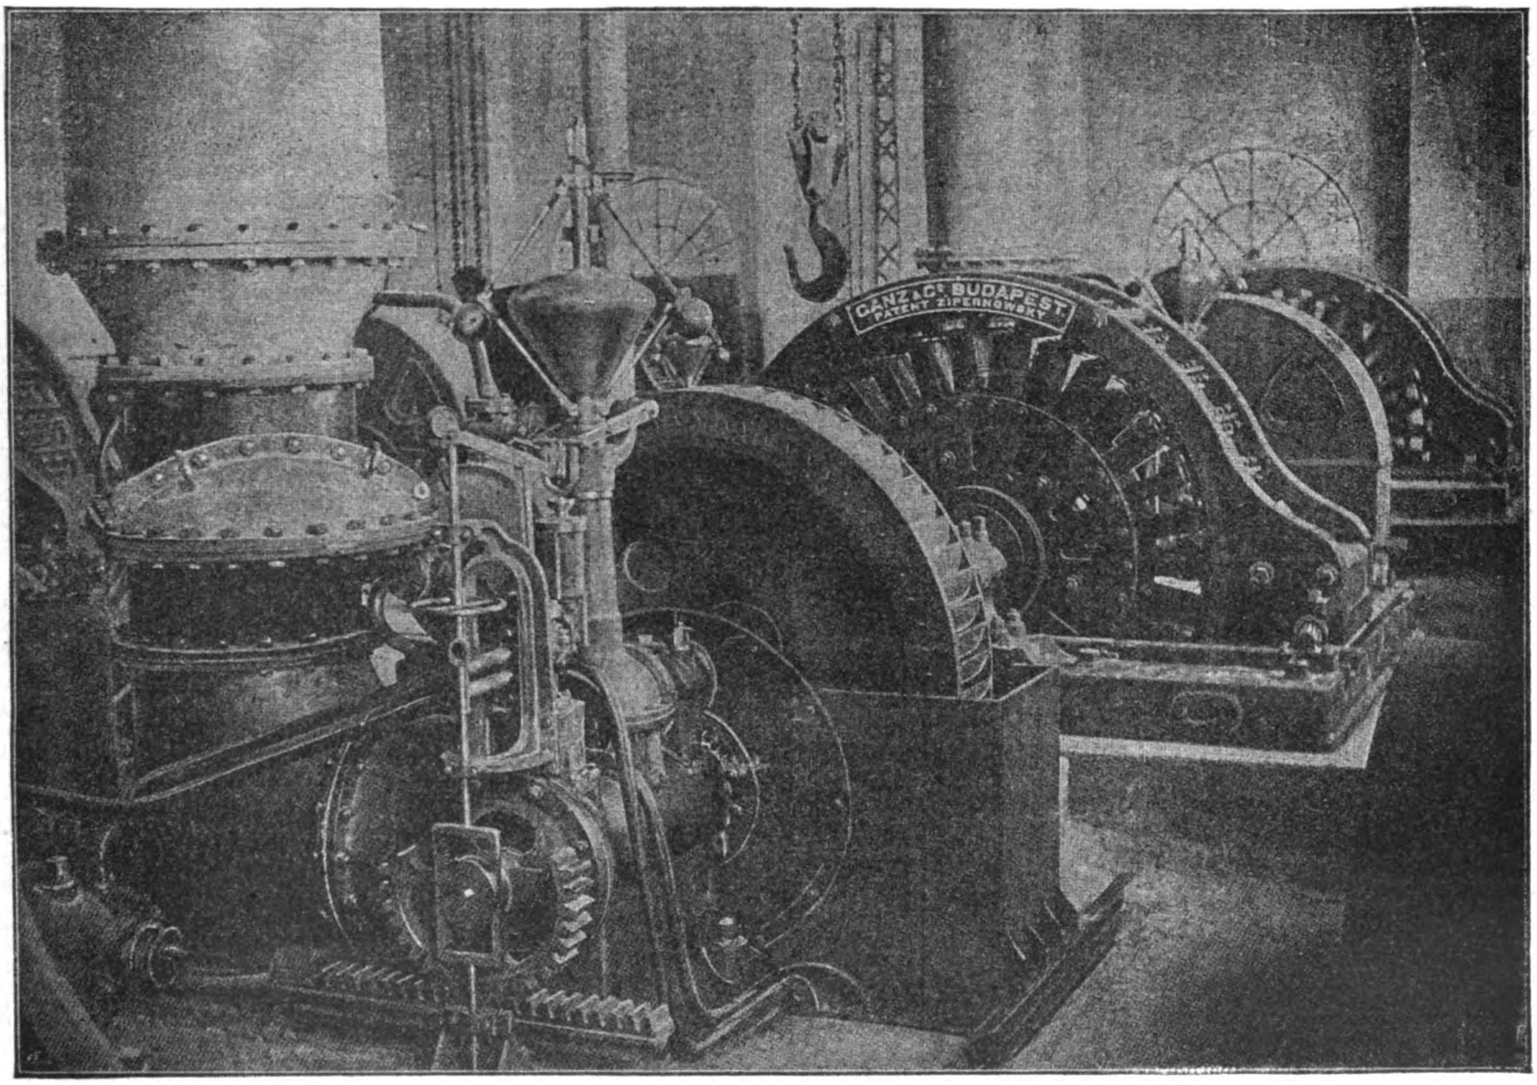
The Muncy Electric Light, Heat and Power Company, Muncy, Pa.—to furnish light, heat and power by electricity to the borough of Muncy. Capital stock, $20,000. Promoters: E. R. Noble, D. B. Dykins, I. B. Painter, all of Muncy.

The Connecticut Royal Arc Company, Elizabeth, N. Y.—to manufacture, operate and deal in apparatus for producing and transmitting light by means of electricity. Capital stock, $500,000. Promoters: G. H. Squires, Plainfield, N.J.; A. Bellamy, C. B. Harris and A. H. Patterson, New York City; F. C. Marsh, Elizabeth, N. J.

The Pullman Electric Company, Chicago—to manufacture, deal in and operate electrical machinery and general electrical business. Capital stock, $25,000. Promoters: F. A. Pullman, David Reid, J. M. Atkinson.

ELECTRICITY.

VOL. V. NEW YORK. NOVEMBER 8, 1893. CHICAGO. No. 17



THE TIVOLI HYDRAULIC-ELECTRIC STATION. (SEE PAGE 198.)

Fraud is Charged.

The General Electric Company Said to Have Been Robbed of $200,000 at Omaha.

Mr. E. A. Kilbourne, formerly assistant auditor in the Chicago office of the General Electric Company, and who has been discharged at various times and reinstated, has given publicity to the charge that he discovered a shortage of something over $200,000 in the accounts of the Omaha office, and was discharged for calling attention to the matter.

Mr. B. E. Sunny, and Messrs. S. L. Wiley and H. E. Chubbuck, of Omaha, it is charged, were the principals. Mr. Kilbourne says the stealings may reach a far larger total.

Mr. Sunny denies the shortage, but admits the truth of all the rest of Kilbourne's statement.

The Tivoli-Rome Transmission.

The large hydraulic station which is operated by the cascades of Tivoli, from which power is transmitted to Rome, Italy, has now been in operation for some time, and has attracted considerable attention among engineers.

The waterfalls which supply this power, it will be remembered, were illustrated in ELECTRICITY, Vol. II, No. 12, and the following description of the plant by means of which this power is utilized will be found of interest :

The origin of the present work may be traced back as far as 1887, when a local company received a charter to divert a certain amount of the water from the falls and to utilize the total fall in several hydraulic stations, for the local industries, for transmitting electric power to Rome and for irrigating purposes.

At that time this company utilized a small falls for lighting in Tivoli, the system being that of Gaulard & Gibbs transformers, with high potential alternating currents.

For several years this was the only work undertaken, but more recently the question of light and power transmission to Rome was revived and the present plant was constructed.

The main features of this are the generating station at Tivoli, the large canals, the transforming station in Rome and the system of wiring.

The main canal, which delivers twelve cubic meters of water per second, has two branches, one of which supplies the power to the generating station, the latter discharging four cubic meters per second. This water is first used for small stations in Tivoli and then passes into a reservoir of 300 square meters surface and two meters deep, from which it is carried to the large station by a series of reservoirs and large pipes. At the station a horizontal pipe 1·6 meters in diameter branches from the main conduit, and runs parallel to the length of the building. From this three smaller pipes run into the building near the roof, and from each of these three vertical columns supply water to the nine turbines.

Of the total fall of 110 meters only about 50 meters is utilized at the station, the remaining fall being utilized further on. The available power, however, provides a total capacity for the station of 2,600 horse power.

The nine turbines, built and installed by Ganz & Company, of Budapest, are of the horizontal axle type, and to each of these is coupled an alternator and an exciter.

A general view of the turbines and alternators is shown in the Frontispiece, which is taken from *Electricité*. Each of these turbines has a special distributor and regulator, both of which are shown in the illustration.

The alternators are of the Zipernowsky type, which is well known. These run at 170 revolutions per minute at full load, generating at that speed 42 amperes each at a pressure of 5,100 volts. The armatures have a diameter of 2·2 meters, and have thirty poles. The efficiency of the machines is 93·5 per cent.

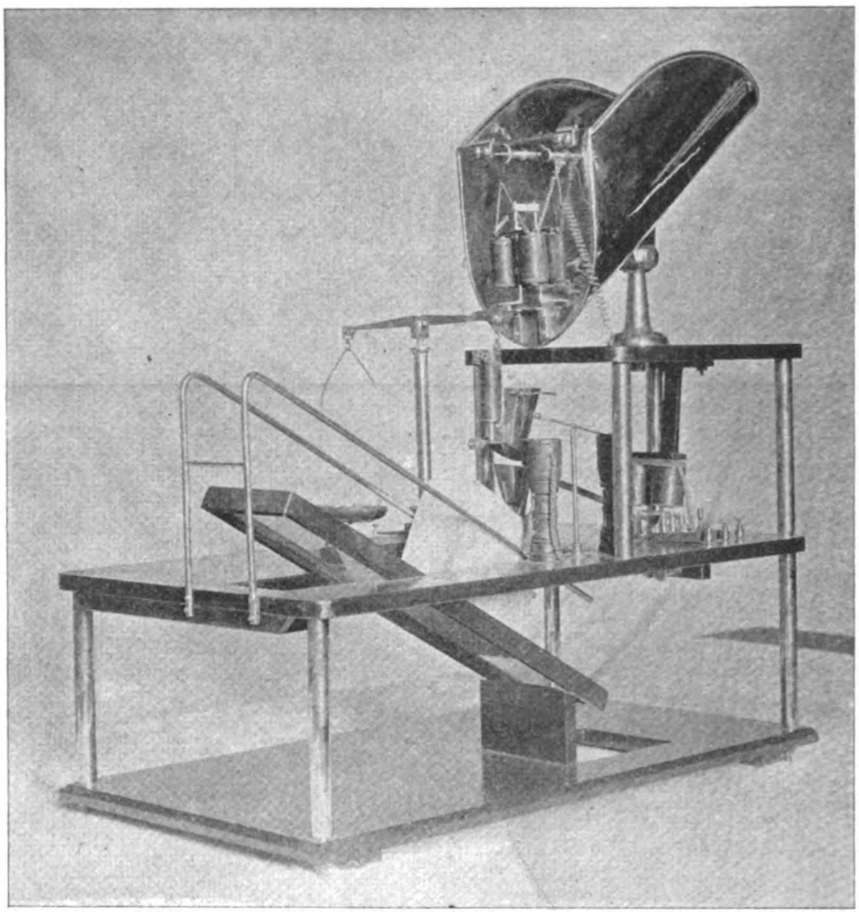
The exciters are four-pole direct current machines with a capacity, at 375 revolutions per minute, of 150 amperes at 180 volts.

An Electric Weighing Machine.

The facility with which electricity lends itself to automatic operations has suggested its use for running weighing machines of this character. One of the latest and most ingenious of these devices has just been completed by Mr. C. F. Wood, of Richmond, Va., and the particular machine described was designed for use in the seed business, in which Mr. Wood is engaged. It is apparent, however, from an examination of this model that but slight modifications are needed to adapt the machine for use with a wide range of materials, and its capacity may be varied to meet almost any requirement.

The object of the invention is to provide an automatic machine that will weigh and deposit in bags, boxes or packages seeds or groceries, such as coffee, tea, spices, baking powder, etc., drugs, or anything else of a granular nature that is offered in commerce. In the seed business the amount of labor and money expended in this work is considerable, some of the larger firms putting up from ten to twenty-five millions of small packages, weighing from one-tenth of an ounce to one ounce, which cost from twenty to thirty-five cents per 1,000 to put up. The way this is generally done is by measuring. This method is inaccurate, and the machine to be described overcomes this inaccuracy by weighing each package, besides doing the work four or five times more rapidly than can be done by hand. The cost of power to run it does not amount to over one dollar per month, as this can be obtained from a gravity battery; or a power circuit divided up with resistance boxes would run fifteen or twenty machines for weighing small packages. The machine can be made of any size, and will weigh practically any quantity from five grains to a thousand pounds or more. It is so arranged that when a weight is placed in the scale pan it regulates the size of the orifice in the reservoir hopper, so as to give the weighing as much speed as possible consistent with accuracy. For instance, take a machine built to weigh packages of from one-fourth to one pound. For a one-pound package there should be a larger opening in the hopper than for a quarter-pound one, as otherwise the former would be too long in weighing, so it is regulated so that when a large weight is put on the scale pan the orifice is large, and as the balance is gradually reached by the merchandise flowing into the receiving vessel the orifice is gradually made smaller until it reaches a certain size, which allows but a small quantity to run in to complete the exact weight.

The machine, illustrated herewith, consists of a reservoir hopper tilted forward so as to give momentum to the materials inside, and having an aperture cut out of its front at the bottom, which is opened and closed by a door sliding in grooves and actuated by electric magnets. The magnets are suspended on a spring and move freely up or down. When the scale beam swings up it strikes a projecting arm fastened to these magnets, and raises them to a height in proportion to the weight on the other end of the beam. At the same time the electric circuit is completed through them by means of a contact piece on the scale pan and a mercury cup, so that the door, being of iron, is drawn towards the magnets, and raised by the pressure of the scale arm. As the weight is gradually balanced the magnets and door move down to a certain point, and as soon as the requisite quantity of material is obtained the contact is broken, and the door, leaving the magnets, cuts off the small stream flowing in. The scale then swings down, and a plunger enters a mercury cup and closes a circuit which operates to open the bag. The seed is deposited in it by the action of another insulated plunger, which operates the door on the weighing receptacle. As soon as this is done the scale swings back, the door in the receptacle closes, the bag is lifted up over a projection and slides away to be sealed, and the door on the reservoir hopper opens again to repeat the operation. The working is entirely automatic, and each package put up is sure to contain the same quantity. The bags used are ordinary seed envelopes, and are placed on an inclined plane with a roller behind them which forces them into position. As fast as one is filled and removed, another moves down into its place. The machine in its present construction is built only for small bags, and an apparatus is now being perfected that will seal them as they are filled. In the form that boxes are made it can readily be seen that the filling of them will not be nearly as difficult as what has already been accomplished.



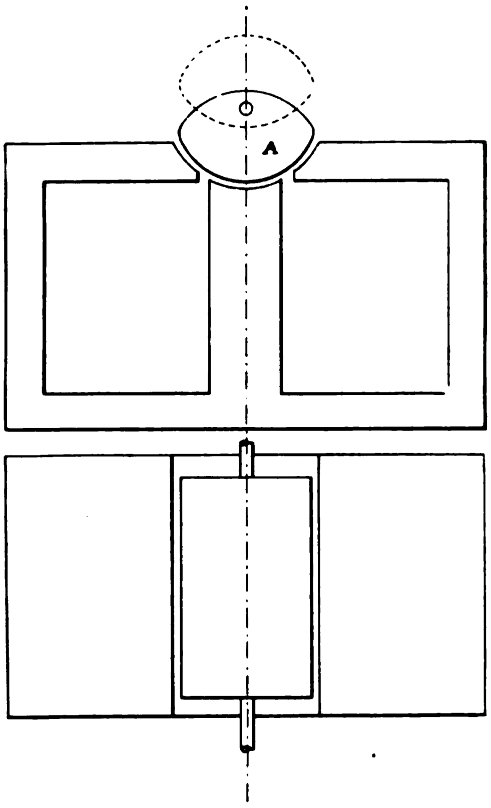
AN ELECTRIC WEIGHING MACHINE.

Transformer Diagrams Experimentally Determined.*

BY DR. FREDERICK BEDELL,

Assisted by A. W. Berresford, W. M. Craft and B. Gherardi, Jr.

Of the various experimental methods used in alternating current work, those are most valuable which ascertain the phase relations of the different currents and electromotive forces, inasmuch as without a knowledge of these relations a full understanding of the phenomena is not possible. Phase relations may be shown by plotting curves representing instantaneous values; or they may be shown by polar diagrams if the currents are harmonic or are assumed to be the equivalent of certain harmonic currents. The representation of the results of alternating current experiments by polar diagrams has an advantage in the fact that such may also be constructed according to theoretical considerations, thus enabling us to compare experiment with theory. The work which is described in the following paper was undertaken with the object of experimentally determining polar transformer diagrams for comparison with similar theoretical diagrams, with particular reference to the effects caused by the variation of the constants of the transformer, as described in a current series of articles entitled the "Theory of the Transformer."†



Arrangement of Transformer. (Half Size.)

FIG. 1.

Experiments were made upon a small transformer, with an output of about 500 watts, constructed and used by Dr. Crehore and the writer for experimental work. This transformer was particularly adapted for the present investigation since it was provided with means for varying the reluctance of the magnetic circuit and thereby the coefficients of self and mutual induction. This variation was produced by the moving of an iron tongue in and out of a gap in the metallic circuit. Figure 1 shows in diagram the magnetic circuit of the transformer and the arrangement of the movable tongue. A laminated iron tongue, A, is arranged so that it may be rotated about an axis occupying the central line of the circular gap which it fills. In the position in which the tongue is represented in the figure, the magnetic circuit is as nearly complete as it can be made. When the tongue is moved through 180° to the dotted position in the figure, the magnetic circuit is most imperfect and the reluctance is highest. The tongue may be moved by an arm and secured in any desired position, and the position is indicated by a pointer moving over a graduated scale.

The essential dimensions of the transformer are as follows:

Length of core (perpendicular to lamination)	2¾ inches.
Width of each plate	5 "
Length of each plate	8 "
No. turns large coil	128.
No. turns small coil	90.
Size of wire in both coils	No. 10 B. & S.
Resistance of large coil	.2272 ohms.
Resistance of small coil	.160 ohms.
Cross section magnetic circuit	12 sq. c.m.

Either coil may be used as primary or secondary.

TABLE OF CONSTANTS.

Changing the position of the tongue alters the reluctance of the magnetic circuit and alters the coefficients of self and mutual induction accordingly; these coefficients increase as the reluctance decreases, and have the highest values when the tongue is all in.

DETERMINATION OF THE COEFFICIENTS OF INDUCTION.

Preliminary to the experiments proper upon the transformer, the values of the coefficients of self and mutual induction of the coils were determined for the different positions of the tongue.

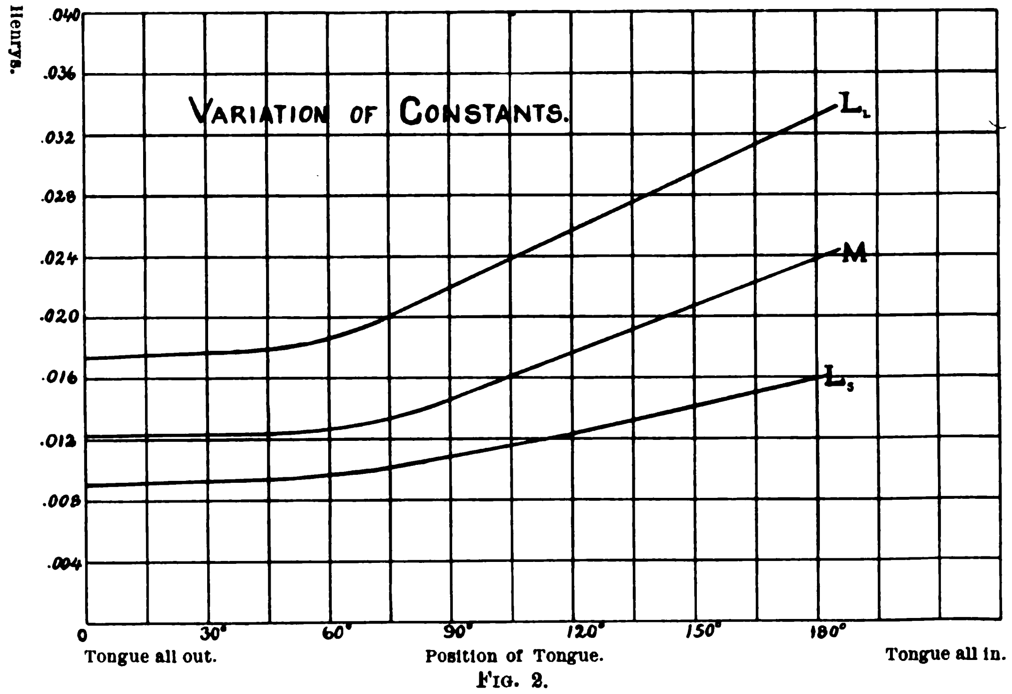

FIG. 2.

For alternating current work, when a reliable voltmeter and ammeter are at hand, the coefficient of self-induction may be readily determined from a determination of the impedance. Measuring the current which flows through a coil when a certain measured electromotive force is impressed, we obtain—

$$\text{Impedance} = \sqrt{R^2 + L^2\omega^2} = \frac{E}{I},$$

where R = ohmic resistance,
L = coefficient of self-induction,
E = electromotive force,
I = current,
ω = 2 π × frequency.

When the ohmic resistance is small as compared with the effect of self-induction, as is usually the case in transformer coils, the value of L becomes

$$L = \frac{E}{I\,\omega}.$$

The coefficient of mutual induction was found by passing an alternating current through one coil and measuring the electromotive force induced in the other. The primary current was measured by a Thomson balance, and the secondary electromotive by a Cardew voltmeter connected across the open circuited secondary. The secondary electromotive force is

$$E_2 = M\,\omega\,I_1,$$

whence the coefficient of mutual induction is

$$M = \frac{E_2}{\omega\,I_1}.$$

As a matter of convenience, the values of the coefficients of self and mutual induction were obtained by simultaneous measurement. The values of these coefficients for six different positions of the tongue are given in the accompanying table.

The position of the tongue is indicated in degrees by the reading of the pointer over the graduated scale, the tongue being all out at 0° and all in at 180°. The two coils of the transformer,

---

[*] Read before the International Electrical Congress, Chicago.

[†] Bedell and Crehore, *Electrical World*, Vol. XXI., No. 12, March, 1893, et seq.

either of which may be primary or secondary, are distinguished as the "large" and the "small" coil, and by the subscript letters $_L$ and $_s$, respectively.

In obtaining the coefficients of self and mutual induction for different positions of the tongue, observations were made for different values of the current. The values obtained for the coefficients decreased as larger currents were used, this variation extending through a range of five or six per cent. Mean values were taken corresponding to the currents used during the experiments and the coefficients were considered constant.

The coefficients increase steadily as the arm is moved in from 0° to 180°, but not by equal increments. The positions 0°, 70°, 90°, 120°, 150° and 180° were afterwards used as giving approximately equal increments to L and M. The values of L and M for different positions of the tongue are plotted in Fig. 2.

The column headed M (computed) in the table gives the values of the coefficient of mutual induction computed from the values of the coefficients of self-induction of the two coils, according to the formula based on the assumption of no magnetic leakage,

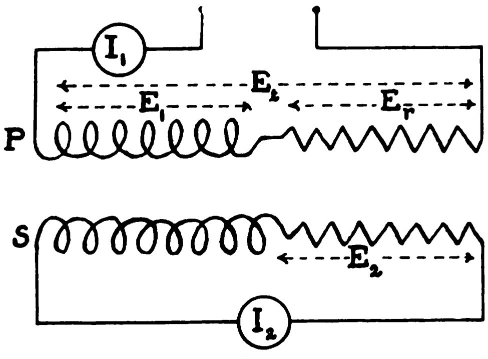

Diagram of Connections.

FIG. 3.

$$M = \sqrt{L_1 L_2}.$$

The values of M thus computed agree very closely with the observed values.

The column headed $\frac{L_L}{L_s}$ gives the ratio of the coefficients of self-induction for the two coils, which we would expect to find equal to the square of the ratio of the number of turns of the respective coils, or

$$\left(\frac{128}{90}\right)^2 = 2.$$

The observed ratio approximates quite closely to this.

Experiments were made with the transformer on constant potential and also on constant current. The constant potential circuit was supplied with a current of such a frequency that $\omega = 2\pi n = 863$; while for the constant current, $\omega = 2\pi n = 566$. In the table are given the values of the inductance obtained by multiplying the coefficients of induction by ω.

METHOD OF MEASUREMENT.

In the experiments proper with the transformer the connections were as shown in Fig. 3. In series with the primary was placed a non-inductive resistance consisting of incandescent lamps. The three-voltmeter method was used to determine the primary power and the angle of lag θ_1 between primary current I_1 and electromotive force E_1. This necessitated a measurement of the primary current, obtained by a Thomson balance, and the differences of potential between the terminals of the transformer, around the non-inductive resistance, and around resistance and transformer together. The secondary load was non-inductive, and the secondary current and electromotive force measured directly.

The quantities observed in making the runs were:

E_1—The E. M. F. around the primary.

E_r—The E. M. F. around the external resistance.

E_t—The total E. M. F. around the primary and resistance.

I_1—The current in the primary.

E_2—The E. M. F. in the secondary.

I_2—The current in the secondary.

From this observed data the following results were computed:

θ_1—The angle of lag between the primary electromotive force and current.

W_1—The watts supplied to the primary.

W_2—The watts in the secondary.

R_2—The secondary resistance.

θ_2—The angle of lag of secondary current behind the secondary impressed electromotive force. The primary angle of lag is calculated by the formula for the three-voltmeter method

$$\cos\theta_1 = \frac{E_t^2 - E_1^2 - E_r^2}{2 E_1 E_r}.$$

The primary power is $W_1 = E_1 I_1 \cos\theta_1$.

The secondary power is $W_2 = E_2 I_2$.

The secondary resistance, being non-inductive, is calculated by the fall of potential, thus

$$R_2 = \frac{E_2}{I_2}.$$

The tangent of the secondary angle of lag is

$$\tan\theta = \frac{L_2 W}{R_2},$$

from which θ_2 can be readily obtained.

(To be continued.)

Tramways for Cairo.

Mr. Frederic C. Penfield, United States Agent and Consul General, notifies to the State Department that the Egyptian Government has decided to authorize the establishment of a system of tramways in Cairo and its environs, and the matter is already attracting the attention of European capitalists and engineers. The introduction of tram lines, Mr. Penfield says, would improve to a great extent the methods of transportation and communication in Cairo, and, if demonstrated a public convenience, a similar concession for Alexandria would doubtless be early decided upon, consequently it may safely be predicted that there will be some competition to secure the franchise. Bids will be received by the Minister of Public Works, Cairo, until the 1st of February, 1894. The permanent population of Cairo is roughly estimated at 500,000, of which 30,000 are Europeans. In the winter season the latter figures would be greatly augmented by the influx of travelers.

"The death of Joseph Creighton last week," says the Omaha *World-Herald*, "recalls one of the most stupendous enterprises ever crowned with failure," for it was he and his brother Edward who planned the prodigious enterprise of connecting Europe, Asia and America by telegraphic communication by way of Alaska, Behring Strait, through Siberia to Russia and across Europe, which the success of the ocean cables, at the time dubious, put an end to.

Lamp Bank Rheostats.

BY C. W. SWOOPE.

It is the prevailing custom with all electrical manufacturers to subject every piece of machinery, instrument or apparatus to a special test before it leaves the factory, the purpose being twofold, to insure the customer satisfaction and to protect the manufacturer. These tests are designed to duplicate as far as possible the the actual working circumstances and conditions in which the apparatus would be placed when on regular duty. Sometimes the current from a dynamo under test, or ammeter being calibrated, is switched onto the shop circuits and utilized, while at other times it is run into any resistance which will absorb it, such as water boxes, iron rheostats or lamp banks. Water boxes answer quite well in many cases, but the objection is the constant regulation required, owing to the change in the temperature of the water, thus producing a varying resistance. The lamp bank, or a series of rows of lamps connected up and switched on the circuit by various devices, is the most satisfactory, as the resistance is constant and the load varies only with that of the main source of supply. They are built and connected up in many forms for different conditions, and the combinations that can be obtained, similar to a rheostat, are quite numerous.

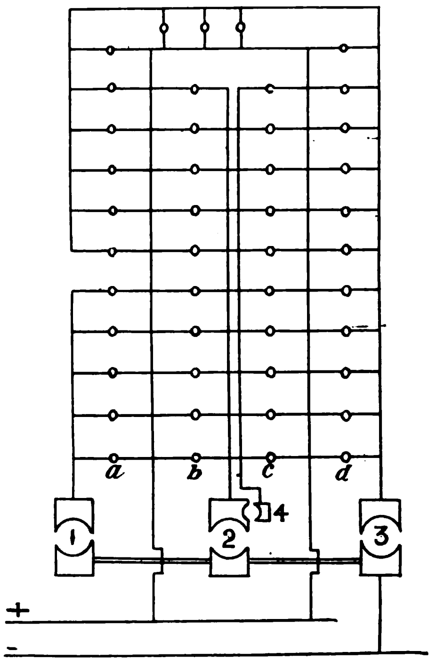

FIG. 1.

Several forms are given herewith, and some combinations showing the range of resistance when properly designed. An ordinary bank is illustrated in Fig. 1, showing connections for four rows of lamps to a single pair of mains. Keyless sockets or receptacles are mounted upon a framework, and the wire terminals from each row brought to lugs made of copper or brass; and for any connection all that is necessary is the insertion of a brass plug, usually mounted on wood or hard rubber handles.

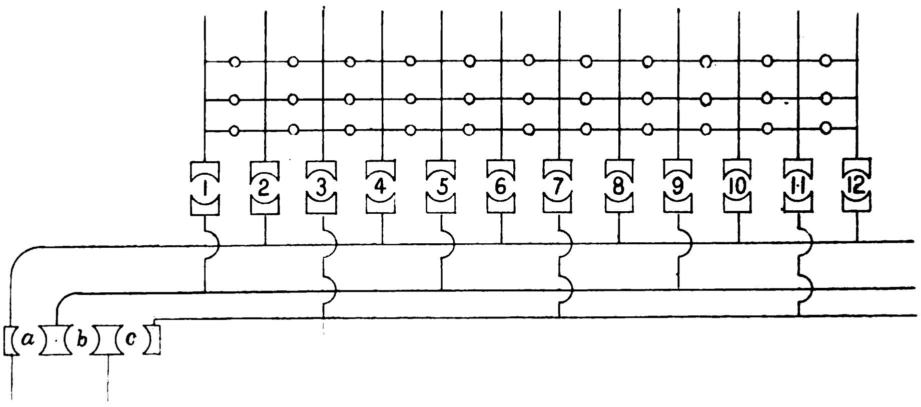

FIG. 2.

In Fig. 1, which is a multiple bank only for use with large loads and voltages not exceeding that of one lamp, quite an even ascending scale

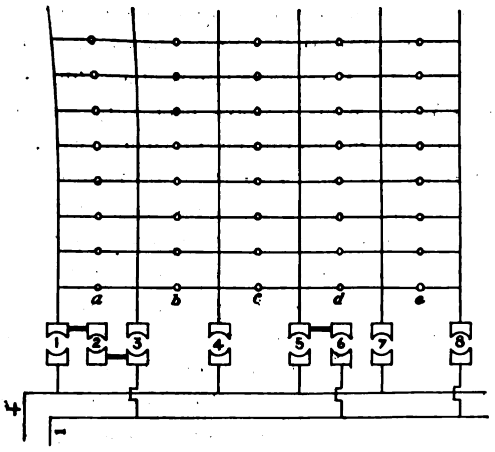

Fig. 3.

of variations can be obtained by choosing the proper number of lamps in the various rows. Connecting 5 lamps on row a, 10 on b and c respectively, and 20 on d, we get the following range of lights:

No. of Lights.	Combination. Plug in.	
5	1	
10	2	4 out
15	1 and 2	4 "
20	3	4 "
25	3 and 1	4 "
30	3 and 2	4 "
35	3 2 1	4 "
40	3 2	4 in
45	1 3 2	4 "

For more variations lamps of different candle power requiring a different amount of current could be used, and for larger loads increase the number of lamps per row, or the number of rows, the latter of course being preferable, thus increasing the combinations. Multiplying each row by 10, the range would be from 50 to 450 lights, the amperes depending on the amperes per lamp.

A multiple or series bank is illustrated in Fig. 2, operated from a single pair of mains, the voltage of the circuit being limited only by the number of rows in the bank. It is well adapted for 125 volt, 250 and 500 volt circuits. For all rows in multiple, on 125 volts or less, insert plugs in b and c on mains and plug 1 2 3 4 5 6 7, etc., on branches. With only one lamp in each row of eleven rows, at 1 ampere, it would give a range from 11 amperes, all in multiple, to $\frac{1}{11}$ all in series, with all the series multiple and multiple series arrangements between these limits. For 250 volts, plug a and c on mains, and 1 3 5 7, etc., on branches—10 rows, range 5 amperes to $\frac{1}{2}$ ampere. For 500 volts, plug b and c on mains, 1 6 11, etc., on branches—range 2 amperes to $\frac{1}{2}$ ampere. 1 and 11 would be plugged for 1,000 volts and so on. Figure 3 is an especially good form for loads not extra large and accurate loads requiring many gradations. To give some idea of its flexibility the following combinations have been calculated, giving the resistance in ohms and current for each combination. Only *one* lamp, 110 volts, was placed in each row, and each one of a different size or candle power. Of course with the same size lamps some combinations would be identical :

Row	a	16 C. P.	.5 amp.	220 ohms.
"	b	20 "	.75 "	145 "
"	c	25 "	1.0 "	110 "
"	d	32 "	1.2 "	90 "
"	e	50 "	2. "	55 "

The table is given in the order of the increasing resistances :

Nos.	Combination.	Plug in.	Resistance of Combination.	Current with Combination.
			Ohms.	Amperes.
1	a, b, c, d, e in multiple	1 3 4 6 7 8	20	5 5
2	b, c, d, e " "	3 4 6 7 8	21	5 4
3	a and b in series, c, d, e in multiple	2 4 6 7 8	23	4.7
4	c, d, e " "	4 6 7 8	24	4.5
5	a, b, c in series, d, e " "	1 6 8	30	3.6
6	a, b, c, d in multiple	1 3 4 6 7	31	3.5
7	d, e " "	6 7 8	32	3.4
8	b, c, d " "	3 4 6 7	36	3.05
9	a, e " " b, c in series	1 3 5 7 8	37	2.9
10	a, e " " b, c, d " "	1 3 7 8	39	2.8
11	b, e " "	3 4 7 8	40	2.7
12	c, d " " a, b in series	2 4 6 7	43	2.5
13	e " " a, b " "	2 4 7 8	44	2.5
14	e " " a, b, c " "	2 5 7 8	45	2.4
15	a, b, c " "	5 2 or 1 6	47	2 3
16	a, b, c in multiple,	1 3 4 5 6	48	2.2
17	e " " a, b, c, d in series	2 7 8	49	2.2
18	a, b " " d, e " "	1 3 5 7 8	53	2.07
19	e " "	7 8	55	2.
20	b, c " "	3 4 6	61	1.8
21	a, d " " b, c in series	1 3 6 7	62	1.7
22	a, b " "	1 3 4	87	1.2
23	b " " c, d, e in series	3 4 8	89	1.2
24	d " "	6 7	90	1.2
25	c " " a, b in series	2 4 6	106	1.03
26	a, b, d, e " "	2 4 5 8	108	1.01
27	c in multiple,	4 6	110	1.
28	a " " b, c in series	1 3 5	118	.93
29	a " " b, c, d " "	1 3 7	134	.82
30	b " "	3 4	145	.75
31	a " "	1 3	220	.5
32	a, b in series	2 4	365	.3
33	a, b, c, d " "	7 2	565	.19
34	a, b, c, d, e " "	1 8	570	.19

The following three combinations might also be added but they give values similar to some in the table :

Like 6.	a, b, e in multiple.	plug	1 3 4 7 8.	31 ohms.
" 17.	c, d " "	"	4 6 7.	49 "
" 21.	a, b " " c, d, e in series	"	1 3 4 8.	62 "

Another form of bank, Fig. 4, is admirably suited for many variations, it being used considerably on bridges, resistance boxes, connecting batteries, etc. Most any combination is readily attainable, and an examination of the figure will be sufficient to explain the method of connections by which the various degrees of resistance may be obtained.

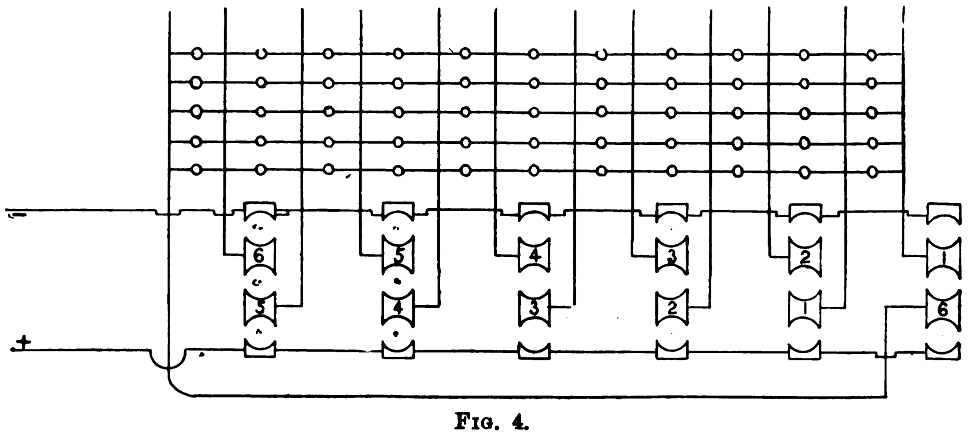

Fig. 4.

The Hydrograph.

The remarkable property possessed by water for conducting sound is well known, but we are not aware that any successful attempt has hitherto been made to turn that property to account for signalling purposes. Its utilization in that direction, however, seems to have been effected in a practical manner by Captain Neale, who has devised a system by means of which signals can be given, messages exchanged, and conversation held between ships on the sea or on rivers, whether moving or stationary, or between ships or lighthouses and harbors, forts, or piers on the shore, or vice versa. Communication, moreover, is effected, without any connection whatever between the two objects except the body of water in which the ships float or the lighthouse stands, the water being the sole medium through which the message is transmitted. The system depends for its action upon harmonics, and its principle will be understood by a reference to the well-known fact that upon a musical note in a given key being sounded an object capable of emitting sound in the same key will, under certain conditions, sympathetically respond by emitting a sound similar to that which awakened its vibrations. It is, of course, a primary condition that the two objects shall be normally tuned in unison. Working upon this fixed principle, and utilizing the high conductivity of water for the transmission of sound, Captain Neale has constructed a signalling apparatus, which consists of a transmitting and receiving instrument, which, when in operation, are in no way connected with each other except through the medium of water. The apparatus as described by the London *Electrical Engineer* is mounted on two punts, the transmitter on one and the receiver on the other. The transmitter consists of a bell about 16 in. diameter attached to the lower end of a framing which is fixed to the side of the punt, the bell being submerged about 6 feet. At the upper end of the framing is a crank handle, which is worked from the punt and actuates a double-beat hammer which strikes and sounds the bell. The Morse code is employed, and signalling is at present carried on by hand, but electricity is intended to be used. The operator gives the handle a quarter turn for the dots of the code, and a whole revolution for the dashes. The receiver, which is on the second punt, consists of a pair of metallic drums, about 10 in. diameter, open at one end and fixed, mouth to mouth, upon a piece of board which is sandwiched in between them. These drums are suspended in the water, and are connected up with a small battery, and through it with a tape recording instrument. As at present arranged, the operator has an acoustic apparatus connected with the drums, by means of which he hears the sounds from the bell as they are received by the drums, and, by a manual arrangement, he records each sound on the tape. Upon the occasion of the inspection, the two punts were moored in the Thames at Kingston, about two-thirds of a mile apart, and signalling was successfully carried on from one to the other. Messages were correctly transmitted and recorded, although naturally somewhat slowly, owing to the apparatus being at present worked by hand. The trial, however, is said to have demonstrated the practical character of the invention and the correctness of the principles upon which it is based.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:

BOSTON:
W. S. KEY, - Room 75, 320 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:
As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

Electric Railway Legislation. The State Railroad Commissioners have for some time been collecting information to enable them to frame regulations for the speed of electric railway cars in thickly settled districts, as well as to recommend the most approved appliances on these cars for the safety of pedestrians.

In the last issue of ELECTRICITY we pointed out the fact that the antagonism to electric railways which is frequently expressed is directed more particularly against the speed of the cars than the method of propulsion. If the list of trolley car accidents that have occurred be examined carefully, it will be seen that almost without exception these have resulted solely from collisions. Accidents from contact with the current are almost unheard of.

Admitting the justice of this view, which is unquestionably established by the statistics of several years, the problem of regulating the speed of street railway cars, and not the motive power to be used, presents another consideration of interest to the public.

The conditions of street traffic are so different in different cities that the question of making a general rule to limit the speed of street cars is not easily determined; nor can such a rule be very strictly enforced.

It is reasonable to assume that the interests of any railway company are best conserved by acceding as far as possible to the demands of the public, from whom its income is derived, but it is also evident that in regard to speed public opinion is divided, as residents and pedestrians along these routes object to just the conditions which the travelling public call for. The rapid and extensive introduction of trolley roads has been undertaken in almost every city where they are found for the purpose of building up outlying districts for which a horse car service has proved inadequate.

In this respect trolley roads have been eminently successful, and this result is due entirely to the rapid and regular service rendered by them. If safety, therefore, compels a reduction in car speed to that of horse cars, the trolley loses its chief advantage over the latter, and the main object for which it was installed is defeated.

In every large city there is, of course, a certain maximum speed which should not be exceeded, and this should practically depend upon the distance within which a car may be brought to rest from full speed. A car running at the rate of twelve miles an hour which is capable of being stopped within one hundred feet is obviously safer than one running at six miles an hour which requires a longer distance before it can be brought to a standstill, and this introduces the subject of electric-car brakes, which are now almost invariably inadequate in cases of emergency. On probably more than ninety per cent. of all our trolley cars the same pattern of brake is employed that has been in general use on horse cars, consisting essentially of a set of brake shoes hung at one side of a pair of wheels which are brought into contact with the latter by winding a chain around the brake rod. As a rule, only one set of shoes acting on one side of a single pair of wheels is brought into play by the action of the brake handle on either platform, and no matter what the leverage may be the time required to give the chain three or four turns around the brake rod is too long to admit of a sudden stop. This point seems to have been very generally ignored in the equipment of electric cars; and although it is easily possible to provide a brake which by a simple short motion of its handle will lock the wheels almost instantly and cause the car to slide, hardly any attempts have been made in this direction. The brake is certaintly the most important and effective safety device with which a car can be equipped, and had this received the same amount of attention that has been bestowed upon guards and fenders, which generally effect more accidents than they avert, trolley cars would have escaped much of the censure which has fallen upon them.

The most cursory glance will suffice to show that the power required to overcome the momentum of a horse car within a given time is far less than a trolley car requires for the same time. The weight of the latter is approximately three times and its average speed about double that of the former; therefore six times the force necessary to stop a horse car would be required to stop a trolley car in the same time.

As an ounce of prevention is universally held to be worth a pound of cure, the safety device for trolley cars most satisfactory to the public should be designed to control the cars rather than to rescue the victims, and the average pedestrian would unquestionably prefer avoiding a collision to being deposited intact on the most efficient style of fender in the market. Life guards may prove of service in some cases, but suitable brakes would constitute a much more acceptable remedy.

Where a human life is at stake the motorman on an electric car has at his disposal a last resort, which is to reverse his motors at full speed without using the brake. This method is, of course, liable to wreck the machines, but under the circumstances that would be of little consequence. As a rule the machinery would stand the shock, and in that case the car would reverse its direction without advancing much more than its own length. If running at a moderate speed it would be stopped almost instantly.

The most thorough precautions possible, however, will not prevail against the carelessness of individuals, and the person who heedlessly steps directly in front of a moving car puts it beyond the power of the motorman, however alert or careful, to avert accident. Over fifty per cent. of the casualties on electric railways reported last month occurred under these conditions. This is about the only class of people a fender is needed for, and if a suitable one can be found it would probably reduce the number of fatalities of this kind.

Where reasonable care is taken by pedestrians, however, the speed of the cars seems of secondary importance to their controlling apparatus, and in this respect most electric cars are deficient. With brakes of suitable capacity provided, a person crossing the tracks at a reasonable distance from the car would be perfectly secure from danger with a careful motorman. There are a few blocks in almost every city which during certain times of the day are so crowded with cars that only a very moderate speed is practicable, but excepting for these short distances it is not necessary for safety to reduce the speed of cars below the usual figures.

A restriction of that kind prevents the cars from making up time after delays and makes it impossible to maintain schedule time on a road, and safety is as well if not better assured by the use of proper brakes in the hands of careful motormen, without defeating the cause of rapid transit.

……o……

Cause for Rejoicing. It is unnecessary for ELECTRICITY to call attention to the fact that business in our trade is stagnant; that collections are slow; that the demand for small supplies has been reduced to meet the actual necessities of consumers, and that large contracts for extensions and for new plants are unheard of—if we except the single instance of the Niagara Falls plant.

It is, however, proper, and it ought to be wholesome, to point out that the present lethargic condition is only temporary, and that the trade at large—leaving out the General Electric Company—is in far better shape to-day than it would have been if the plans of the sham Trust had not miscarried.

It is doubtful if any one, not excepting the organizers and promoters of the General Electric Company themselves, have given a more careful study to the situation, from the organization of that company up to the present time, than we have; and we refer not alone to the internal affairs of the would-be Trust, but to the possible effects of the scheme on the smaller concerns and on the business as a whole.

ELECTRICITY was the first to raise the danger signal, and though few were found a year ago to admit the correctness of our judgment, there were some. Our original supporters and advisers were not among those who came into the business but yesterday; they were old-timers, men who had watched every move in the game for ten years, who knew just what might be expected of Mr. Coffin and the T.-H. coterie if the power to crush out competition ever came to them.

And as there were few who appreciated the dangers of the situation then, there are many now who believe, in all honesty, that the danger never existed, since it has apparently passed away. Nevertheless, the danger did exist, in a marked degree, and the General Electric organization had in it all the necessary factors for temporary success, save one, a competent man at the head of the concern. With that man, one who had the breadth of perception to see the situation as it actually was, and the masterly patience to wait until it was time to strike, monopoly might have been established and maintained for a number of years.

The General Electric Company started off with ample financial backing, and the glamour of mystery thrown around its business was such as to attract additional capital. New England believed Mr. Coffin to be invincible, and the New Yorkers accepted as real prospective extensions of business which had no more basis of fact than Ferdinand Ward's "Government contracts." Money was plenty in the early months of the company. With competent management, and with a disorganized and scattered opposition, it might have secured a strong position.

A series of blunders, an unbroken course of mismanagement, has forced the General Electric Company into a condition worse than bankruptcy, and left the opposition well prepared, as general conditions improve, to take an overwhelming proportion of the business.

We know not whether association with the rapid men of Wall Street was too much for Mr. Coffin, or whether his head was turned by the frequent references in the daily press—references which are now only a reminiscence—to "Young Coffin, the Napoleon of Electrics"; whether, in fact, the errors of judgment have been his or should be charged to his advisers. Certain it is that the company overreached itself; that it claimed the earth before it had cleared the underbrush from its own land; that it disregarded utterly the strength of the opposition, was wholly oblivious to the perils to itself of the campaign it began; that it ignored all precedents in its overweening confidence, and seemed to prefer enemies to friends.

There is, therefore, honest cause for jubilation on the part of the independent concerns who trimmed their sails in the early days of the present financial storm, and who are thus prepared to take early advantage of improving conditions.

The grip of the General Electric Company is forever broken, and the dark clouds which hung over the trade are clearing away, to be remembered only as a temporary object-lesson of what might easily have been a prolonged period of gloom.

……o……

THE *Electrical World* still keeps up the bombardment of Messrs. Stump, Martin et al. with mud. Our contemporary stands in a unique position, and not at all an enviable one. It is forcing on its unfortunate readers page after page of petty personal matter which only one man in the world is reading, and that one man the writer of the stuff. It is guilty of a serious offence against newspaper ethics in this, and a more serious offence in printing a garbled and distorted report of legal testimony. If any one is in doubt as to whether or not this is legitimate newspaper matter, let him ask himself the question, How much space would the *Electrical World* have given to this lawsuit if it had been between Messrs. Martin and Phelps, or Messrs. Stump and DeGraw?

……o……

SPECIAL attention is called to the announcement on page 207 of the establishment of a Patent Bureau by this paper. Correspondence on patent matters is solicited. Questions of general interest will be answered in these columns, and other matters will receive an individual reply. In the procuring of patents, good service on the part of the solicitor is essential, and that ELECTRICITY guarantees.

Dishonesty in the Profession.

BY G. EMIL HESSE.

Every engineer knows that there is a great deal of dishonesty practised in some branches of the technical profession, and in the front rank stands what is called commissions, which in this instance is another word for bribe.

This underhanded business flourishes both in Europe and here, and it seems as if to a greater extent in this country amongst first-class manufacturers and engineers. The fact is that the engineer is almost flooded with corrupt proposals from manufacturers and sales-agents as soon as it becomes known that he has secured an order of any importance. It is hardly necessary to analyze the question in order to find whether it is right or wrong to serve two masters—your client and the manufacturer.

Every honest man who gives it a minute's thought will condemn it, and his attention should therefore continually be drawn to the baseness of the habit, which in many cases is nothing but a custom.

It seems so natural to accept a percentage from the man who has been favored with the order that it hardly ever crosses the mind that there is anything wrong in the transaction.

To an engineer with an elastic conscience no such appeal as the above would have any effect, but the picture has also another purely practical side that touches the pocket. The system is as well known to the client as to the engineer, and he is consequently on the lookout. The result of such a transaction is very often disastrous, and I know personally one case where a man was employed at a salary of over $5,000 a year, and who probably drew as much in commissions from various manufacturers, but with the inevitable result of losing the former and consequently the latter. This is by no means a rare instance, and many others could be mentioned, but it goes to show that honesty pays in the long run.

Another pernicious custom is the appropriation of other people's ideas and inventions that is constantly taking place. This is generally practised by engineers in the employ of manufacturers. As an example I could mention an incident that took place about a year ago in one of the largest electrical concerns in the country. An inventor sent them a model of a machine that would do a certain thing cheaper and better than the old method. The company at once set a man to copy the machine and applied for and obtained a patent. They then returned the model with a polite letter saying that they had no use for it, as they already had similar machines working themselves.

I happened to know the draughtsman who copied the machine, and this was not the company's only experience in that line.

It should be the ambition of every man to raise his profession to a high moral level and meet every attempt to drag it down with contempt. The sooner an engineer realizes that he has a reputation to work for besides a living, the better for himself and for the profession that he belongs to.

The Wyandotte Squabble.

The Wyandotte, Mich., electric light litigation, noticed several months ago in ELECTRICITY, has been settled by the courts. The contract with the Wyandotte Electric Light Company to light the city for five years is held to be invalid, and the city is enjoined from recognizing the local company's contract or paying any money on account of it. The contract for the municipal plant is also declared invalid, leaving the city to go ahead and make a new bargain for one.

The decision is without prejudice to the Western Electric Company, which retains the right to sue to recover the price of the plant it has put in for Wyandotte.

Special Paper on "Traction and Street Railway Trucks."—II.

BY ELMER A. SPERRY.*

As to gearing between the axles, the bevel gear presents by far the simplest solution. This form of gearing, however, has been looked upon as wasteful of the power transmitted. The criticism is probably just for some power transmissions employing this gearing. The question is, How much more power does a bevel gear and pinion absorb than a spur gear and pinion in transmitting the same amount of power, with the conditions identical? There seem to be almost no conclusive or carefully made tests of merit as to the comparative losses in transmission of power by these two classes of gears. Fig. 2 shows a diagrammatic view of an apparatus designed by the writer for testing this feature, with which an exhaustive series of tests covering this point has been made. B is a car axle mounted in journals, D D. E is a hydraulic dynamometer, with lever arm, E, and weight, F. A is an electric motor delivering its power to a pinion co-operating with a gear mounted upon the car axle, B, C being a flexible connection between the motor and the pinion shaft. The car axle was three and three-eighths inches in diameter, and two kinds of gearing were employed between the axle and the motor. A bevel gear and pinion (shown in the diagram) inclosed in an oil housing, G, were alternately tested with a spur gear and pinion, also mounted within an oil housing. When the spur gear was used, the motor was set at right angles to its position as shown in the diagram, and parallel with the axle, B, and connected with the shaft of the spur pinion. It will readily be seen that the conditions under which these tests were made were as nearly alike as it was possible to make them, and at the same time the transmissions took place under the same conditions that obtain on a street car truck. Numerous curves were plotted, showing total losses between the electrical terminals of the motor and the dynamometer, showing gear losses losses resulting from shoulder and journal strains produced by the gearing and all the bearings, in each test through the entire range from starting to about sixty horse power input. Submitted herewith, in Figs. 3 to 8, inclusive, are curves showing that under practical working conditions, when the bevel gear is properly made, the losses are almost identical with spur gear, the small difference, viz. 1.74 per cent., in favor of the cut gear, probably being due to the fact that the surfaces were somewhat rougher in the cast than in the cut gear. The great care exercised in these tests and the clearness of the results certainly speak volumes in favor of the bevel gear transmission, and constitute the first comparative tests of large transmissions under heavy strains which to the knowledge of the writer have been made.

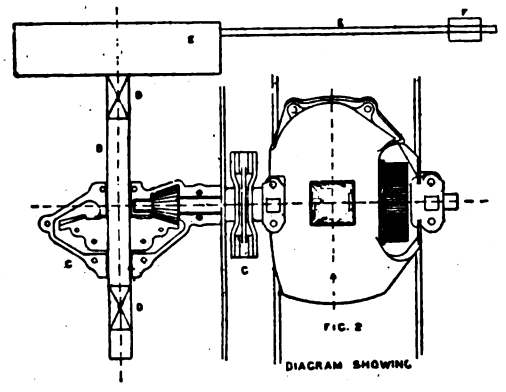

FIG. 2.

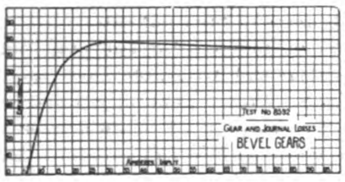

FIG. 3.

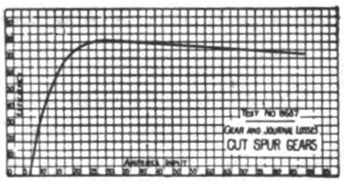

FIG. 8.

Another feature bearing directly upon the all important question of traction is that of axially mounted masses. Locomotive drivers and axles are as light in themselves as is consistent with required strength. The inertia of a large mass axially mounted does not allow the drivers to follow the surface irregularities of the track with anything like equal pressure, especially at high velocities. The wear and tear of the roadbed are also due in large measure to the heavy masses attached directly to the axle. All weights of magnitude should be spring supported.

Referring now to the tests, a track was built consisting of forty-five pound T rails rising from a spur of level track, having a mean grade for the two rails of 12.4 per cent. Upon this grade was run, first, a double motor equipment weighing 17,935 lbs. A dynamometer was attached to the drawbar and back to the track in such a line as not to either lift the car or drag its rear end downward in the test. Current was then applied through a variable resistance, gradually allowing the car to strain upon the dynamometer until finally the wheels slipped. Care was especially exercised on the point of gradual application of the strain so as to eliminate all elements of inertia or lunging forward upon the dynamometer; after slipping had commenced it was observed that the car would slide in each instance to the bottom of the grade. The following table gives the mean of four sets of readings:

INDEPENDENT AXLE, TWO MOTOR EQUIPMENT.

Drawbar pull on dynamometer. Car standing on 12.44 per cent. grade. Weight of equipment, 17,935 lbs.

Group of Tests.	Average Amperes.	Average Drawbar Pull.	Ratio of Drawbar Pull to Weight.
1	1,625	200 lbs.	9 per cent.
2	2,250	280 "	12.5 "
3	2,150	240 "	12 "
4	2,075	230 "	11 "

This car was run off the grade and replaced by one in which all the wheels were compelled to revolve in unison, but of much lighter weight, viz. 12,685 lbs. The dynamometer was attached in the same way and the same rheostat and source of current were used as in the previous experiment, the axles in the equipment being coupled by bevel gears.

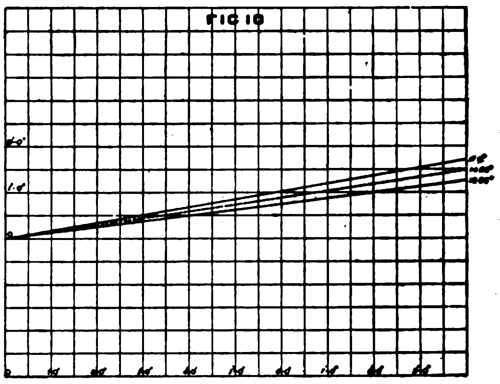
The following table gives the mean of five sets of readings taken on this car:

COUPLED AXLES, SINGLE MOTOR EQUIPMENT.

Drawbar pull on dynamometer. Car standing on 12.44 per cent. grade. Weight of equipment, 12,685 lbs.

Group of Tests.	Average Amperes.	Average Drawbar Pull.	Ratio of Drawbar Pull to Weight.
1	200	3.125 lbs.	24 per cent.
2	240	3,750 "	30 "
3	230	4,075 "	32 "
4	220	4,500 "	35 "
5	200	4,375 "	34.4 "

The same operator applied current to the car in both tests, and every condition of electrical pressure, track and weight remained identical throughout.



The car was then run off the track and the rails blocked, as is shown in Fig. 10, one rail having 12⅝ inches rise in 10 feet, the other having 17.2 inches, making a mean of 14.92 inches rise in 10 feet, equalling a grade of 12.44 per cent., giving a warp of considerable magnitude to the roadbed. This warping, shown in Fig. 10, would at once reveal any rigidity introduced into the truck by the coupling, and would be apparent in the ratio of drawbar pull to the current absorbed if any part of the equipment was bound, unduly strained, or working under any but perfectly normal conditions. The following table shows the readings taken, and is conclusive as to the perfect freedom of the truck while working in this warped and highly distorted position.

COUPLED AXLES, SINGLE MOTOR EQUIPMENT.

Drawbar pull on dynamometer. Car standing upon warped track.

Right rail........................ 14.33 per cent. grade.
Left rail........................ 10.58 " "

Weight of equipment, 12,685 lbs.

Group of Tests.	Average Amperes.	Average Drawbar Pull.
1	230	4,425 lbs.
2	220	4,875 "
3	200	4,150 "
4	220	4,275 "

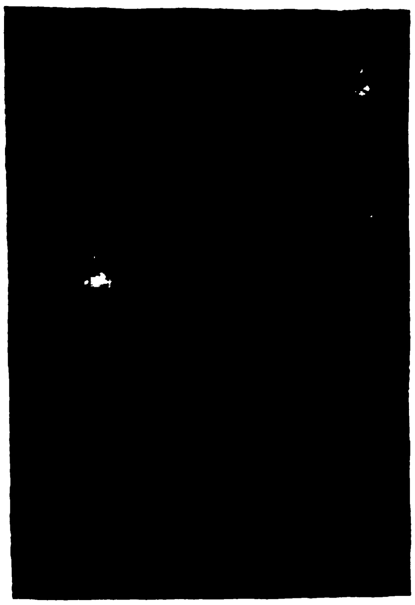
It will be readily understood that when an equipment is running on a grade the centre of gravity of the car lies nearest to the rear wheels, thus allowing the front pair to slip when independently driven. After slipping commences the tractive value of the front motor becomes almost *nil*, as shown by the traction curve in Fig. 1, the work being undertaken almost entirely by the rear motor, whereas with coupled drivers, and especially where a single large motor is used, the motor is compelled to deliver all its power to the rear wheels if the exigency so requires. At the same time the front wheels, instead of slipping, are compelled to revolve in step with the back wheels and bite the rails in unison therewith, and in fact all the wheels are held down to the business of effective non-slipping adhesion, this being true in whichever way the car approaches the hill, and whichever pair of wheels is respectively forward or rear. This great difference in favor of coupled drivers shows a percentage of 35 as compared with 12.5 of the total energy appearing as actual pull at the drawbar under the conditions named.

---

* Abstract of paper read at the American Street Railway Association Convention, Milwaukee.

In running on a level, and especially in damp weather with a slimy rail, almost the same increase in traction as shown here will be found to exist with coupled wheels, provided always the mechanism used in coupling does not interfere in the least with the flexibility of the truck.

(Concluded.)



A Curious Lightning Discharge.

Modern Uses of Electricity—I.

Professor Charles R. Cross, of the Massachusetts Institute of Technology, is engaged in giving a course of twelve lectures on "Modern Uses of Electricity," in Huntington Hall, in connection with the Lowell Institute. The course is to extend over six weeks, one lecture being given every Monday and one every Thursday evening.

The first of the course was given Monday evening, October 30, to a large and appreciative audience. In entering on his subject the lecturer remarked that some definitions of the nature of the agent employed and of certain terms usually employed were necessary to be explained, and in stating, in the first place, what electricity *is not*, he referred to the fact that the questions with which physical science is concerned are *matter* and *energy*. Matter is possessed of mass and inertia, and in virtue thereof refuses to enter into motion except as the result of the application of force.

Energy is the capacity of doing work by virtue of motion or position. An illustration of this is the weight in a clock, or a coiled spring, or a heated body, all of which represent the potentiality of work by reason of work already done to them; and in this connection the lecturer referred to the law of the conservation of energy and the indestructibility of matter. The capacity for doing work in any bodies cannot be affected from within; it must be affected by the application of some force.

Professor Cross then went on to say that electricity, whatever it is, is not energy; that while heat and motion are convertible into energy, electricity is not so convertible, and in this respect is analogous to water, the energy of a falling mass of which is utilized without the disappearance of the water, while in the case of energy derived from heat or motion, the heat or the motion as such ceases to exist.

It further appeared probable that electricity is not matter, although it must be admitted that the experiments on this point are not absolutely final. We do, however, know certain well-defined facts with regard to electricity—for example, if we connect by a wire the two poles or terminals of a voltaic cell, we find that some change takes place in the wire and the space surrounding it, and this change we call a current of electricity. We know that an alteration or change takes place in the condition of the circumambient luminiferous ether; also that an electric charge given to a body results in a condition of strain which is removed by discharge. Vibrating the rapidly successive charges and discharges produces rapid stresses and relaxations; and if these vibrations are carried on at a sufficient rate, they produce the phenomena called light.

The lecturer objected to the usual method of describing the laws of electricity as mysterious or occult. On the contrary, so far as these laws have been formulated, they are clearer and more exact than the explanation of the so-called and well-known law of gravitation, which may be said to be that all bodies attract one another directly in the ratio of their masses and inversely as the square of their distance, which leaves the whole matter about where it was. Other examples were the definitions of an atom or of matter itself.

The term electromotive force, as analogous to mass-moving force, means the force by virtue of which a current of electricity is forced or is tended to be forced through a conductor. Potential or difference of potential signifies difference of electrical level, the current flowing or tending to flow from a point of higher to a point of lower potential as matter does

The point of potential of the earth is taken as the *datum* or *zero*. If current flows from a glass ball or other positively charged body to the earth, it is said to be of a higher potential, and if the flow is from the earth to another body, as in the case of silk, then the body is of lower, and in this case negative, potential.

The term *pressure* is practically synomyous with potential. All generators of electricity, whether frictional machines, batteries or dynamos, operate by producing a difference of potential by setting up an electromotive force. The analogue of this, in hydro-dynamics, is the force pump which operates by producing differences of pressure. In both cases the current results. Generators of electric currents may be fairly called electricity pumps.

Again, it should be observed that electricity, by whatever name it is called, or however set in motion, is one and the same thing, although its manifestations vary infinitely.

The words "static" and "dynamic," often used in connection with electricity, if they mean anything, simply mean electricity at rest and electricity in motion.

The idea usually held, that current is forced through a wire or other conductor in somewhat the same manner as water is forced through a pipe, has now been displaced by the idea, suggested first by Clerk Maxwell, that the current is the result of ether stresses produced in the space surrounding the wire. As all practical commercial forms of electricity are now produced by the instrumentality of magnets, the consideration of magnetism and its phenomena becomes important.

All bodies possess this property, steel and iron most abundantly, nickel in a less degree, and all things to some extent, though in most cases feebly.

By means of diagrams, Professor Cross then illustrated some of the magnetic phenomena, such as the arranging of iron filings around the opposite poles of a bar magnet, etc.

In showing these he said it should be remembered that each line of force must begin at one pole and end at another. The lines are invariably closed curves, and cut, as Faraday said, like stretched filaments, tending to break and also tending to repel each other. These lines cannot end in space, but must return to the opposite pole of the system.

The revolution of loops of wire and of magnets was illustrated by experiments and diagrams; also Maxwell's rule that an electric circuit in a magnetic field tends to set itself so as to embrace the greatest possible number of lines of force, or at right angles to the field.

SOCIETY NEWS.

The New York Electrical Society's First Meeting of the Season.

The first meeting this season of the New York Electrical Society was held at Columbia College Tuesday evening, October 31st, at which a paper was read by Mr. D. McFarlan Moore on "Electricity in Advertising." At the close of the paper a number of lantern slides were shown illustrating various effects that may be produced with electric lights for display purposes. Mr. Moore spoke in part as follows:

Owing to the peculiar and almost inexplicable attraction that the word "electric" has upon the general public, it is used to advertise not only such electrical fakes as rings and hairbrushes, but even articles of some intrinsic value, such as glue and soap, the promoters knowing that the public can be deluded by a single word. Nevertheless, electrical manifestations that attracted public attention a comparatively short time ago are now considered unworthy of notice. We all remember when the "great electric arc light" was one of the leading attractions of the country circus, when crowds would gather to see an incandescent lamp nestling among silks and other inflammable materials in a show window, or when an aquarium with a lamp beneath the surface of the water, or a lamp in the centre of a block of ice, would cause much comment, and also the awe and respect which country folk displayed when the "matchless" lamp appeared, which they could not blow out.

Although an illuminated waterfall or a lamp in an aquarium burning under water ceases to cause wonder, the experiment, first shown by Trouvè, of illuminating the body of a live fish by a miniature incandescent lamp which it has been made to swallow, will always attract attention. Insects and bugs made of incandescent lamps are also attractive novelties, as well as photographic plates placed in a case with a lamp behind them.

Curiosity has always been the greatest factor in exciting the interest of Americans, and this is why the most successful advertisements are those by which this sentiment is prominently evoked. The first impulse upon viewing a revolving figure or showcase is to look for the motive power, and to-day this is generally an electric motor, a machine which has almost entirely superseded clockwork.

One of the earliest methods for attracting the public eye was to construct letters or words of small or freely suspended discs of bright metal, and causing the supporting frame to quiver by means of an electrical vibrator. In the street cars of some of our cities a moving panorama of advertisements operated by a motor beneath the seats attracts much attention.

The idea of illuminating signs, supported upon the posts along the line of an electric railway, only when the car is passing, has proved to be successful.

Although all great fairs and expositions represent the progress of the human race, the fundamental principle upon which rests the possibility of their existence is advertising. Therefore, everything connected with a fair which adds to its attractiveness is an advertisement.

The most impressive feature of the World's Fair was the electrical display—in one sense a huge advertisement, from the "writing hand" and Ferris wheel to the electric fountains, which latter are universally described as indescribable. The object of each exhibit was to produce an effect which would distinguish it from all others, and cause it to be remembered. The incandescent electric light was generally adopted to produce this result, and it offers great advantages, being specially adapted for this purpose by the infinite variety of forms in which lamps can be arranged. Although the arc lamp cannot as a rule compete with its miniature rival for decorative effects, nevertheless in a projector it produces results even more far-reaching. The troublesome and expensive calcium light in stereopticon work is to-day largely replaced by the arc lamp. The advertisements that shine forth at night on conspicuous walls in all our cities enable the operator in many instances to reap a rich reward. A little calculation will demonstrate this very clearly. Suppose the wall can be rented for ten dollars a week, and the operator obtain fifty subscribers at one dollar a week; it will be seen that handsome profits can be realized.

Since projectors are now constructed of 40,000,000 C. P., which throw a beam of light 65 miles, the inhabitants within that radius are forcibly reminded of the structure from which the light is; and when even the clouds are utilized as signboards, the question arises, has not advertising now reached its limit.

An ingenious system of composite letters, for spelling out words letter by letter and one letter only at a time, was devised by Kelway in England. It consisted of arranging a number of lamps on a space large enough for one letter, and so wiring these lamps that different combinations at different times would produce different letters. The immense electric sign, 60 x 68 feet, at the south of Madison Square, is the most gigantic in the world. It cost about $6,000 and consists of 107 letters, averaging 6 feet high, and comprises seven sentences. It is composed of lamps of different colors, which are controlled by switches so that they can be made to alternately appear and vanish. The deleterious effects of rain are prevented by placing a small tin shield over each circular hole through which the lamp is thrust into its socket. 1,457 lamps, representing 145 H. P., bestud the letters, which are made of painted tin, so that they are equally effective as an advertisement by daylight. The current for operating this sign is taken from the Edison Illuminating Company's mains, and costs 24 cents per minute when all of the sign is in use.

But the objection to be found with this, as with most other signs, electric or otherwise, is that it is of one fixed design which cannot be changed without great expense and inconvenience. I now have the pleasure, with your permission, of calling your attention to a new system of which I am joint inventor, and which is designed to overcome the last named difficulty, enabling the immediate production of successive widely varying designs consisting of lettering, sketches of almost any description and size, and adapted for use either indoors or in the open air, owing to its great flexibility. Its construction is as follows: Incandescent lamps are arranged in cross section over any given vertical surface to be used as the sign, covering it entirely, that is, they are placed at equal intervals in horizontal and vertical rows and as closely together as advisable. A cable consisting of as many separate wires as there are lamps connects them with a small table, which we will call the operating board. This operating board, placed at any suitable distance, is completely covered with push buttons or circuit closers, arranged close together, so that each little push-button on the small operating board will correspond to a lamp on the large surface used as a sign. It is now evident that by pressing on any single push button or circuit closer a lamp similarly situated on the sign will be lighted.

Simply by writing or drawing on the face of the operating board, pressing on certain buttons, will cause corresponding lamps to light, all others remaining dark, and practically any effect desired can be produced on the sign in a greatly enlarged scale.

With this system under consideration, absolute flexibility is secured. Comparatively small signs will be required for indoor use, and for them miniature incandescent lamps should be used, as it is evident that the smaller the lamps and the closer they are together the more perfect will be the designs. Of course the push buttons are so designed that when pressed down they will continue to keep the circuit closed and will not return to their normal position until the operator so desires. If the push buttons or circuit closers are made substantial and comparatively large, it is found that writing on the operating board in letters six inches high will produce letters six feet high on the sign. Of course the lamps are wired in multiple, and this will require one small wire of capacity for one lamp to connect each lamp with its corresponding circuit closer. These wires of course, being of one polarity, are in the form of a cable. One pole of the feeding circuit is attached to the sign and the other pole to the operating board. By the movement of a lever at the side of the operating board all the push-buttons are released, and an entirely new design can be produced.

It is not necessary that the operator see the sign as it is being produced, because with a bright light behind the operating board, and the push-buttons slightly conical in form, an exact fac-simile of the sign is produced on the face.

An Interesting Legal Case.

A lawsuit of interest to the electrical fraternity has just been decided at Hartford, Conn.

H. Ward Leonard & Company wired a theatre at Middletown for the Middlesex Mutual Insurance Company, who owned the building. The wiring was connected with the local central station. One Sunday evening after the work was completed, and before it had been fully paid for, a fire broke out in the building and did damage to the extent of some $40,000.

The property was insured, and in paying the loss the various insurance companies, six in number, took subrogation contracts enabling them to sue any party they might consider responsible for the fire.

H. Ward Leonard & Company, after repeated demands for the money due them, finally brought suit for the balance due, some $3,800. This was met by a cross bill from the insurance companies, suing H. Ward Leonard & Company for $40,000 damages, claiming that they caused the fire by negligence and improper construction.

H. Ward Leonard & Company pressed their suit and recovered the full amount of their claim with interest and costs.

A sentence of two months' imprisonment, with hard labor, has been imposed upon a London swindler for selling "electric" spectacles at £4 a pair.

Personal.

Mr. J. Holt Gates, Western representative of the Waddell-Entz Company, spent the greater part of last week in New York. He reports several good contracts for his company well under way.

Mr. George O. Fairbanks, who was for a long term of years the manager of the Westinghouse Electric and Manufacturing Company's business in Chicago, has connected himself with the Railway Equipment Company, particularly with a view of taking charge of the Western agency for the Holmes, Booth & Haydens wire, which has lately been given to that company.

HARD TIMES.

A Wail from the Mohawk Flats.

Some time ago I chanced to read
Of hard times down at Lynn,
And how the boys are all compelled
To bluff without the tin;
But if the version was correct,
This truth is plain to me:
The situation's not as bad
As at Schenectady.

My soul grows sad when I recall
The pleasant times gone by,
When every purse—and man—was full
And none was ever dry.
The clambakes at the Aqueduct,
Oh, they were jolly, fine!
And "hurrahs" out on Bellevue,
Or a dance at Brandywine.

To work then in the office
Was the softest kind of snap,
For every man had a roll-top desk
And an easy chair to tap.
Then envelopes were corpulent
On every Saturday,
But now they're very limp and flat—
They hold but three days' pay.

Then the draughting room was crowded
With fellows killing time,
Who wore "biled" shirts and diamond studs,
And made up quite sublime.
But the room is now a'most empty,
The merry crowd are gone
To put their diamond studs in hock,
Their overcoats in pawn.

The testing room was a jolly place,
None merrier in the town,
Its chiefest toil consisting in
Holding chairs and tables down.
The few now left bestir their bones,
With faces worn and meek,
Honyock with crowbars round the place
For three days in the week.

The students, too, once gay and free,
Roam idly through the streets—
The girls don't see the op'ra now,
Nor any other treats.
The boys are broke, and for a time
Are laid upon the shelf,
And so hard up was one galoot
He tried to pawn himself.

Come back, oh happy days, and let
Us blow ourselves once more
In the Edison at evening
As we used to do before.
Restore the games we used to play,
With wallets full and free,
And let us waken up the life
Of old Schenectady!

But what wild ramblings, vain, are these—
To the world we're good as dead,
For, treading light on our uppers now,
We can't produce a red.
A lucky few draw three days' pay,
And faintly can be heard,
But more are silent as the grave
And never say a word.

The "lion and the lamb" is good—
But, friend, just hear the rest,
Remember that who laughs the last
Laughs loudest and laughs best.
The game's not out, some cards are left,
Don't let your fingers burn,
It's ten to one, aye, bigger odds,
That we will call the turn.

Schenectady, Oct. 28. H. R. M.

Patent Department.

While we have been publishing a list of the electrical patents issued each week, to keep our readers informed of the developments in this direction, we have decided that this was not sufficient to meet the needs of inventor and others interested in patent matters. We have, therefore, established a Patent Department in connection with ELECTRICITY, and have made arrangements with Mr. T. F. Bourne, the well-known patent solicitor and expert, of New York City, to manage this department. The object is to afford to inventors and others a safe, reliable and efficient bureau through which they may procure United States and foreign patents at reasonable expense, and with most satisfactory attention to their wants, at the same time giving them such information as to the patentability of their inventions as they may ask for.

We are prepared to procure patents for inventions in all countries, on all classes of devices and improvements, and especially in the line of electricity. Mr. Bourne is well qualified for procuring patents for inventors, he having been practising before the Patent Office for many years with signal success, and inventors cannot do better than to procure their patents through this agency.

If you have invented an improvement in anything, and desire to protect your rights, communicate with us, and have your patent procured through this agency without delay. Write to us for any information you may desire regarding your invention and we will reply, free of charge.

Our charges for procuring patents are reasonable, and will be given upon application.

Address all communications regarding inventions and patents to

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

Current Items.

An ingenious device for ballroom decoration which has recently appeared consists in the freezing of incandescent lamps into large and prettily shaped blocks of ice, which serve the double purpose of giving forth coolness and light.

Some of the London electrical-supply firms are taking very sensible and practical steps to enable the public to readily enjoy the advantages of electric heating. They are not only lending out electric cooking stoves to customers, but are prepared to supply a separate meter and charge half-rates for cooking, which they can afford to do, inasmuch as the consumption takes place during the day when the dynamos must gather electricity, and when there is little demand for it for lighting purposes. Besides these ovens there are breakfast cookers, in which eggs and bacon may be cooked on the breakfast table; electric plate warmers, which are being ordered for London clubs, for they can be kept in the dining-room without any offensive smell; electric foot warmers, hot plates, stewpans, kettles, flatirons, ornamental screens, which act as radiators of heat and warm a room; electric curling-iron heaters for ladies, and electric shaving-pots for gentlemen.

A correspondent of the Pittsburg *Dispatch* states that works for the manufacture of alkali and bleach powder by electricity are about to be established in Virginia, whose climate is supposed to be well adapted to the production of those commodities. In order to overcome the troubles caused by excessively varying temperature, a factory will be built in a huge excavation in the side of a mountain, and here the bleach chambers will be erected. The property is underlaid by a fine deposit of rock salt, and has a surface deposit of excellent limestone. There is plenty of good timber, and not distant coal fields will supply fuel at fairly cheap rates. The methods of alkali manufacture hitherto in vogue have been tedious, crude and expensive, and the introduction of electricity into the industry opens out new and remarkable possibilities. The electrolytic process, or the decomposition of common salt by electrolysis, is the only direct means of producing by one operation caustic soda and chlorine gas. The value of this process can be seen by comparing its results with those of the old methods. By one standard process 18 cwt. of salt will give one ton of salt cake, but it requires two tons of salt cake to yield one ton of caustic; and therefore 36 cwt. of salt is required to make one ton of caustic and 16 cwt. of bleaching powder. By electrolysis it is calculated that 36 cwt. of salt will yield one ton 16 cwt. of caustic soda and two tons 6 cwt. of bleach. In other words, at present prices the profits on bleaching powder will be nearly tripled, and on caustic nearly doubled.

Recently in Milwaukee four hundred telephones were rendered useless as a result of a trolley wire coming in contact with a telephone wire, the strong current of the former being conducted into the terminal room of the telephone exchange. A vertical strip of current arresters four feet high, on each side of which are trained the subscribers' wires, was speedily ignited and it burned to the top. Twenty-five cables containing subscribers' wires, which are carried from the arresters to the switchboard, were destroyed, rendering about 400 lines unserviceable. The failure of the arresters to act is a mystery.

Boston Notes.

The work of surveying the district for the new electric street railway that is to connect Boston with the popular seaside resort, Winthrop, is being pushed ahead, and the State Board of Railway Commissioners has given a hearing this week to an application for a charter. It is expected that as soon as authority is given work will begin on construction of the road.

A new device has been invented by Mr. George L. Hall, of Lynn, Mass., by means of which he can render dead when necessary any wire charged with electricity. It is called an electric cut-off, and works most satisfactorily. The inventor has already made and installed quite a number of these devices in various power stations around Boston.

The Northampton, Mass., Electric Light Company has just closed a contract for the erection of a new plant that is to cost $50,000 when completed.

The Wanoosnoc Power Company is the name of a new corporation organized in Portland, Me., with a capital of $20,000, to furnish electric power for mechanical and manufacturing purposes.

As yet there has been no final settlement of the dispute in the city of Cambridge about the laying of car tracks along the classic thoroughfare, Brattle street. Each party is equally persistent in urging their side of the case, and when the end will be deponent sayeth not. Meanwhile the people walk through Brattle street and appear as if satisfied to walk forever if only the modern vandals will hold off their ruthless hands from marring the street in dispute.

Accelerator cars is the name of a new type of car now being introduced by the West End Railroad Company of Boston, the distinctive feature of which is a pair of doors placed at the corners of the ends of the cars, and so unlike the single door at present occupying the centre of the ends of the cars. This construction has been adopted so as to facilitate the entering and leaving the car by passengers, which is now too often an unpleasant undertaking when the platform is crowded with passengers standing. Of course only one of the doors will be open at a time—the one on the side of the car furthest from the adjoining track.

General News.

What is Going on in the Electrical World.

Hartford, Conn.—Efforts are being made to organize a stock company at East Hartford to carry on an electric business.

Olathe, Kan.—The electric light plant here has been purchased by B. E. Morrison, of Newport, Ark., who will at once take charge of it.

Richmond, Va.—I. Bluford, of this city, has invented a device for shearing horses by electricity which does the work in one-third the time required by hand.

Fond du Lac, Wis.—The Fond du Lac Light, Power and Railway Company has fulfilled its promise to the public in equipping its electric road in first-class style.

Hamilton, Ohio.—There appears to be a strong desire among the citizens for a municipal electric light service, and meetings have been held to discuss the subject.

Madrid, Ia.—Mr. E. T. Pardee, of Clinton, representing the Fort Wayne Electric Company, has secured a franchise for a lighting plant here, and will begin work at once.

Leavenworth, Kan.—An ordinance has been passed by council giving Receiver Newman Erb the right to change the present street railway lines into an electric system.

Milwaukee, Wis.—There is a block in the transfer of the Milwaukee Electric Railway, the Hinsey line, to the Villard syndicate, which was to have taken place November 1.

Muncie, Ind.—The Citizens' Electric Street Railway Company has changed its old line into an electric system. A first-class 250 H. P. engine has been purchased for the power house.

Dundee, Ill.—The Dundee Rapid Transit Company has, it is said, completed arrangements to connect the river towns, Dundee, Elgin, St. Charles and Aurora by an electric railway.

Cleveland, O.—The electric light mast in the public square has been reduced from 250 feet in height to 135 feet, improving the light.—Electric light meters are to be placed in all the hotels.

Hoosick Falls, N. Y.—Ground was broken a few days ago for the new electric railway to connect North Hoosick and Waloomsac. It is likely that the road may be in time extended to Bennington, Vt.

Chicago.—The Electric Launch and Navigation Company reports having carried over 1,000,000 passengers in its electric launches with safety during its six months' operations at the World's Fair.

Fort Worth, Tex.—Stratton & White, electrical and general implement dealers, have filed a deed of trust for $400,000, with but $50,000 preferred. The failure of the company is a severe blow to Fort Worth business circles.

Scranton, Pa.—Arthur Lewis and William F. Hessel have opened an electrical supply house in this city, and will carry a complete line of electrical goods. Both of the men were lately in the employ of the Electric Light Company.

Port Huron Mich.—An electric railway from Port Huron to Maryville, St. Clair and Marine City will be built in the spring the St. Clair River Railroad Company having been organized for that purpose with a capital stock of $300,000.

Peoria, Ill.—The immense fly-wheel of the General Electric Company plant burst on the morning of the 30th ult., completely wrecking the front of the works and ruining valuable dynamos and machinery. The damage is between $15,000 and $20,000.

Brooklyn, N. Y. The New York and New Jersey Telephone Company propose to establish pay station telephones in bar-rooms and drug stores, many of these places charging the public for use of their telephones, which are rented for private use only.

Colorado Springs, Col.—The Lowe Gas and Electric Company has gone into the hands of a receiver, Irving Hawbert having been appointed to take charge. The company owns the only gas works here, and one of the two electric light plants. L. P. Lowe is manager.

New York.—The Commercial Cable Company has received a blue ribbon, preliminary to the delivery of a medal from the World's Columbian Exposition, for the best system of working ocean telegraph cables, and for the Cuttriss improved cable and telegraph apparatus.

Albany, N. Y.—It is believed here that no experiments will be made this year in the application of electricity to the propelling of canal boats.—The electric heating of trolley street cars has become an important branch of the business of the Consolidated Car Heating Company.

Newton, N. J.—The contract of the gas company for lighting the streets expires shortly and the residents generally have expressed themselves as favoring electric light; it remains therefore for either the gas company, a private corporation, a new company, or the town to furnish what the people demand.

Salt Lake City, Utah.—W. H. Rowe, R. M. Jones, J. W. Summerhays and George M. Cannon have petitioned city council for a franchise for an electric railway which they intend to extend to Big Cottonwood Cañon if they are given the right of way in the city.

Sharpsburg, Pa.—The Allegheny and Kiskiminetas Electric Street Railway Company is making a move to secure a right of way from Tarentum to Etna borough, through Sharpsburg, to connect with the Allegheny and Manchester electric line. The new company has secured a charter for operating the line between Tarentum and Sharpsburg.

Indianapolis.—Walker Brothers & Company, brokers, of New York City, have instituted suit in the Federal District Court at Indianapolis against the Muncie Street Railway Company and Citizens' Street Railway Company of Muncie to recover $5,500, claimed to be due as commissions earned in effecting the sale of the property and franchises of the Muncie Street Railway Company to Russell B. Harrison.

Rochester, N. Y.—The new train safety apparatus invented by Dr. J. H. McCartney, president of the Railway Electric and Automatic Signal Company, has been tested on the Delaware, Lackawanna and Western Railroad. The operation of the new device was witnessed by a number of railroad men and others, and was pronounced satisfactory. It resembles in some respects the block system. The system not only protects a line of straight tracks, but it renders collisions on sidings and switches well-nigh impossible.

Washington, D. C.—Col. Bullock and other representatives of the Universal Electric Company of New York, appeared before the District Commissioners a few days ago and presented the claims of the company of having "the best system of electric traction in existence." (The system is that which was tested on Coney Island a short time ago, and was explained at the time in ELECTRICITY.) The commissioners heard the details with apparent interest, but came to no determination as to its adoption in Washington.

Cincinnati.—The new Telephone Exchange, on Vine, near Fourth street, was opened for business on the 28th ult., at which time the telephone system of the city was changed from overhead wires to the subways.—A test of the Salamander fireproof and waterproof wire was made in the shops of the Card Motor Company last week, under the direction of a representative of the Washburn & Moen Manufacturing Company of Worcester, Mass., and proved a success. The electrician of the local board of fire underwriters witnessed the test and subsequently remarked that the wire filled every requirement for a fireproof electric wire.

Paterson, N. J.—The New Jersey Improvement Company proposes to build an electric railway line from Paterson to New Brunswick, passing through Montclair, Orange, Plainfield, Metuchen, etc., following the line of the Orange Mountains. The length of the proposed line is forty miles. The following are the officers of the company: President and general manager, Jacob L. Stapleman, of Bala, Pa.; secretary, John N. Bethel, of Philadelphia, Pa.; treasurer, Charles E. W. Smith, of Morristown; directors, Lewis E. Mans, of Philadelphia, Pa.; Roland F. Hill, New York; William N. Mills, Boston, Mass., and A. D. Thompson, Plainfield.

Vancouver, Br. Col.—The *Advertiser* says: "There has just been added to the Vancouver Electric Street Railway and Electric Light Works a fine piece of machinery in the shape of a Westinghouse 250 H. P. generator, capable of furnishing illumination required for 2,500 incandescent lights. So accurately is it constructed and placed in position that one can scarcely detect by sight that the parts are revolving with such high velocity. Connected with the generator is a small agitator. Both have the latest improvements in their construction. The machine has an automatic regulator so delicate that whether one light or 2,000 are burning the current remains steady."

The leading feature of the *Review of Reviews* for November is its presentation of the "Possibilities of the Great Northwest," in an article by Mr. S. A. Thompson, and in a supplementary article by Dr. Emory R. Johnson, upon "Inland Waterways for the Northwest." Mr. Thompson, as secretary of the Duluth Chamber of Commerce, has for several years been actively engaged in searching out and applying effective means for bringing the great States northwest of the Upper Mississippi, and the great Canadian Provinces belonging geographically to the same region, into closer communication with the rest of the North American continent. He is therefore able to write with an enthusiasm born of intimate knowledge of the subject and supported by very important and surprising statistics. Dr. Johnson is lecturer on Transportation in the Wharton School of Finance and Economics, University of Pennsylvania, and has recently published a monograph upon "Inland Waterways." Dr. Johnson particularly emphasizes the importance of canal and river transportation as a means of lowering railway rates, and he finds a very large social as well as economic influence resulting from this extension of facilities for shipping and for personal travel. These two articles suggest a future of almost unimaginable growth for the great Northwest. Each article is fittingly illustrated.

INCORPORATIONS.

The Michigan Electric Company, Detroit, Mich.—to manufacture and sell electrical appliances and do electrical engineering. Capital stock, $10,000. Promoters: Geo. A. Manfield, Joe E. Lockwood, Detroit; Francis B. Stockbridge, Kalamazoo, Mich.

The Victor Electric Light, Power and Water Company, Victor, Col.—to erect and operate electric plants, etc., to supply the towns of Victor, Fremont, Lawrence and Barry in El Paso County, Col., with light, etc. Promoters: Wilbur K. Honson, H. E. Woods, J. E. Rockwell, Victor, El Paso County, Col.

The Cripple Creek Electric Company, Cripple Creek, Col.—to operate an electric plant for furnishing light, etc., for Cripple Creek and vicinity. Capital stock, $100,000. Promoters: Robert P. Davie, Hiram Wilson, Willis S. Montgomery, Cripple Creek.

The American Novelty Company, Minneapolis, Minn.—to manufacture electrical machines and novelty devices, etc. Capital stock, $100,000. Promoters: Ed. H. Darrow, Albert E. Pray, Truman E. Penney, Minneapolis.

The Roslyn Light and Power Company, Roslyn, Wash.—to manufacture and sell light, heat and power and do general electric lighting. Capital stock, $17,000. Promoters: Chas. A. Sprandel, Mrs. Lena Sprandel, E. C. Sharpe Roslyn.

The Union Heater Supply Company, at Detroit, Mich.—to manufacture plumbers', trainmen's, electricians', dentists' and painters' specialties. Capital stock, $10,000. Incorporators: B. Rein, George C. Huebner and Catherine L. Huebner.

The People's Light, Heat and Power Company, Camden, N. J.—to manufacture and supply heat, light and power either by electricity, gas or other means. Capital stock, $100,000. Incorporators: Edward Dudley and Henry B. Wilson, of Camden; Selden Twitchell, of Philadelphia.

The Sidney Electric Company has filed notice at Columbus, Ohio, of an increase of capital stock from $15,000 to $25,000.

The San Francisco Bonet Electric Tower Company, Chicago. Capital stock, $150,000. Incorporators: Leo Bonet, Marie Dubois and W. H. Munich.

The Northfield Light, Heat and Power Company, Northfield, Minn.—to manufacture, supply and sell light, heat and power, and own real-estate and plants necessary for the manufacture and supply of such light, etc. Capital stock, $20,000. Promoters: J. W. Hilliard, J. C. Nutting, M. W. Skinner, A. W. Norton, D. J. Ferguson, C. A. Drew, B. Kelly, J. S. Tripp, H. O. Dilley, F. J. Wilcox, Northfield.

The LeRoy Electric Light, Power and Heating Company, LeRoy, Ill.—to supply electric light, heat and power in LeRoy and vicinity. Capital stock, $10,000. Promoters: L. A. Crumbaugh, A. J. Keenan, L. A. Reynolds, Amos Rutledge, S. D. VanDeventer.

The Electric Motor Company, Duluth, Minn.—to manufacture electric motors and electric and mechanical attachments and appliances relating thereto and used in connection therewith. Capital stock, $100,000. Promoters: D. H. Merritt, Geo. J. Northrop, Marquette, Mich.; Frank W. Merritt, Arthur R. Roe, Duluth, Minn.

The People's Power Company, Rock Island, Ill.—to furnish light, heat and power, and sell appliances for same. Capital stock, $300,000. Promoters: Theo. B. Davis, Samuel S. Davis and Chas. O. Nason.

The Atchison (Kan.) Electric Railway and Light Company has filed an increase of its capital stock from $250,000 to $300,000.

The Inter-State Telephone Company of Kansas City, Kan., has been chartered at Topeka. Its capital stock is fixed at $100 000.

The Buttermilk Falls Electric Company, Highlands, N. Y.—to manufacture and use electricity for light, heat and power. Capital stock, $15,000. Promoters: Chas. F. Roe, Geo. W. Flood, Highland Falls; Walter C. Anthony, Newburgh, N. Y.

The Philadelphia *Press* of the 3d inst. says: "The Pittsburg Electric Company yesterday took out a charter at Harrisburg. It is claimed, and apparently with good reason, that when the last Legislature re-enacted the corporation law of the State, and omitted electric light companies from its list, it necessarily repealed all legislation authorizing the incorporation of such companies. Until the Supreme Court settles this question no one can be certain that he can safely make contracts with an electric light company chartered since this repeal went into effect. The new Pittsburg company, therefore, will need to invest in a lawyer before it does in a dynamo."

The Deming Land and Water Company, Deming, N. Mex.—to construct street railways and electric light plants in Deming, etc. Capital stock, $700,000. Promoters: Paschal R. Smith, Samuel C. Hobart, Chas. F. Thayer, Jas. L. VanArsdale, Chas. E. Easby.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED OCTOBER 17, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

506,770. Elevated Railway. James F. Cranston, Springfield, Mass., assignor of one-half to Michael Craven, same place. Filed May 23, 1892.

506,993. Electric Railway Conduit. Henry H. Franklin, Brooklyn, N. Y. Filed July 13, 1893.

507,064. Trolley Wire Hanger. Benjamin B. Betts, St. Louis, Mo., assignor of one-third to Emil A. Kolbe, same place. Filed Dec. 28, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

506,733. Manufacture of Electric Lamps. Hermann Schulze-Berge and Frank G. A. Schultze-Berge, Brooklyn, N. Y. Filed March 23, 1893.

506,890. Electric Arc Lamp. August Utzinger, Nuremburg, Germany, assignor to Schuckert & Company, same place. Filed Dec. 15, 1892.

DYNAMOS, MOTORS, ETC.

506,740. Dynamo-Electric Machine. Sidney H. Short, Cleveland, Ohio, assignor to the Short Electric Railway Company, same place. Filed April 13, 1891.

506,774. Dynamo-Electric Machine. Fritz A. Feldkamp, Newark, N. J. Filed Nov. 15, 1892.

506,775. Dynamo-Electric Machine. Fritz A. Feldkamp, Newark, N. J. Filed Nov. 19, 1892.

506,786. Electric Locomotive. Hosea W. Libbey, Boston, Mass. Filed April 21, 1892.

506,881. Regulator for Dynamo-Electric Machines. Jeremiah Keller, Canton, Ohio. Filed Oct. 10, 1891.

506,920. Electrical System of Distribution. Cyprien O. Mailloux, New York, and William S. Barstow, Brooklyn, N. Y. Filed April 27, 1893.

506,921. System of Electrical Distribution. Cyprien O. Mailloux, New York, and William S. Barstow, Brooklyn, N. Y. Filed June 23, 1893.

506,927. System and Apparatus for Raising Water. John H. McGowan, Cincinnati, Ohio. Filed Dec. 4, 1890.

TELEPHONE AND TELEGRAPH APPARATUS.

506,658. Multiple-Commutator Apparatus for Telephone Systems. Louis A. Berthon, Paris, France, assignor to the Societe Generale des Telephones. (Reseaux Telephoniques et Constructions Electriques). Filed June 15, 1892.

506,884. Apparatus for Suppressing Telephone Disturbing-Currents. Frank A. Pickernell, Newark, N. J., assignor to the American Telephone and Telegraph Company of New York. Filed June 6, 1893.

506,978. Printing Telegraph. Lewis P. Buck and Frank D. Sweeten, Wilmington, Del. Filed July 26, 1892.

MISCELLANEOUS.

506,683. Junction Box for Electric Cables. Samuel B. Fowler, Chicago, Ill., assignor to the Standard Underground Cable Company, Pittsburg, Pa. Filed April 12, 1893.

506,700. Automatic Sprinkler and Fire Indicator. Joseph S. Kiehl, Chicago, Ill. Filed Oct. 19, 1892.

506,729. Electric Push Button. Benjamin F. Rex, St. Louis, Mo. Filed Feb. 16, 1893.

506,830. Insulated Electric Conductor. Leonard F. Requa, New York, N. Y. Filed Dec. 24, 1892.

506,841. Electric Alarm System. George F. Bulen, Bayonne, N. J. Filed July 5, 1893.

506,883. Visible Signal. Frederic S. Perrin, New York, N. Y., assignor to the American Telephone and Telegraph Company of New York. Filed May 15, 1893.

506,936. Electric Synchronizer for Clocks. Henry S. Prentiss, Elizabeth, N. J. Filed Nov. 3, 1892.

506,957. Method of Manufacturing Copper Wire. Emile Viarengo, Turin, Italy, assignor to the Val D'Aosta Syndicate, Limited, London, England. Filed April 5, 1892.

ELECTRICAL FORGING COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 210.)

Electrical Forging.

The exhibit of the Electrical Forging Company of Boston at the World's Fair, which is illustrated in our Frontispiece, proved one of the attractive points in Electricity Building, and the applications of the process which were carried on in this booth attracted the attention of large crowds of visitors almost constantly.

The generator operating the machinery was of a special design, of 75 H. P. capacity, producing a current about 1,800 volts and 25 to 35 amperes. From the generator the current is conducted to the transformer carrying the massive copper conductors leading to the various styles of jaws or electrodes between which the different shapes of metal bars, etc., to be heated are placed. The transformer is four-sided and the electrodes are so arranged that a number of men may work simultaneously about the device. The power of the transformer is such that the current is changed from the high intensity of 1,600 to 1,800 volts down to 30 volts while the amperage is proportionally increased to 8,000 or 10,000.

One of the principal features of this system is the regulation, and this is accomplished by placing a rheostat in the exciter circuit instead of the dynamo circuit; the most sensitive regulation can thus be obtained.

As the details of this system have already been given in Electricity, the reader is referred to the previous description of this interesting and novel application of machinery.

A New Danger from Lightning.

Mr. A. A. Voysey gives an account in *Industries* of an apparently unusual cause of damage by lightning. In a room in a country house near Nottingham stood a table "ornamented by a fringe fastened securely to it by nails. This fringe had been almost entirely burnt on the side of the table facing the room, and the burning had partially extended to one other side. The wood was charred to a depth of $\frac{1}{8}$ to $\frac{1}{4}$ of an inch where the fringe was burnt. If the table had been struck by lightning there must have been some marks in the room showing where the discharge had entered and where it passed to the earth. But not a mark or sign of any kind could be found, and the damage to the table was completely isolated. A rigid inquiry proved that no one had entered the room with a candle. The only possible explanation of the occurrence was suggested by an examination of the fringe. It was found to consist of a fluffy material, probably a mixture of cotton and wool, and certainly of an inflammable nature. Interspersed among the fluffy material were fine metallic threads. Now it is in this combination of inflammable material with the metal threads that the explanation lies. The metal threads were acted on inductively by the lightning discharges taking place near the house. This inductive action was sufficient to cause small sparks to fly between various threads, and the sparks set the inflammable material on fire. If the fire caused in this peculiar manner had not quickly died out, the whole house might have been destroyed, and no sign would have been left to point to the true cause. It is not unusual for fires to occur in connection with thunderstorms, and they are generally attributed to the direct action of a lightning discharge. Possibly a large percentage of such fires have been caused by induction, and the simple incident which has come to my notice is sufficient to show how easily the inductive action may cause a fire."

Electric clocks that automatically ring bells at the end of each recitation hour or period, are being put into a number of New England schools.

The Artificial Lighting of Workshops.

BY BENJAMIN A. DOBSON.[*]

In manufacturing districts the use of artificial light is of considerably greater importance for work of all descriptions than it can be elsewhere. Whether the work be fine or coarse, delicate or bold, a better light is needed than for work which does not come under the head of manufacture. In Lancashire the staple industries of engineering, machine-making, spinning, weaving, bleaching and dyeing, are mainly established in certain centres; and with them is invariably associated in the surrounding district the great coal industry. Although Lancashire coal has a number of excellent qualities, yet it is one that makes the most smoke of any. A large portion of the manufacturing industries, great and small, date from a number of years back, when smoke-consuming and smoke-preventing apparatus had not yet been devised; and many of the factories are working at the present day under pretty much the same conditions as when they started. Hence the atmosphere in all manufacturing towns in Lancashire is heavily charged with unconsumed carbon, producing an excess of cloud and fog, which, while inducing an excess of rain, acts also as a screen against the rays of the sun, and thus does a double injury to the neighboring agriculturist, the producer of the country's native wealth. A circle of thirty miles radius around Manchester is said to include a larger population than an equal circle around any other place in the world; and within this circle, about twelve miles northwest of Manchester, lies Bolton, the town with which the author is best acquainted, where all winds, except the west and northwest, bring the surcharged atmosphere from other manufacturing districts, producing at any season of the year, if the wind happens to be slight, a sky ranging from dull lead to dark brown. For four years in succession it has occurred at the writer's works that on June 21, the longest day, the gas in every room, amounting to nearly 7,500 jets, has had to be lighted by 11 o'clock in the morning, and has remained lighted until work ceased; and this has occurred also in other towns and in weather that ought to have secured abundant sunshine. To such an extent does gloom prevail that in clear weather the effect of bright sunlight becomes even distressing to the eye-sight, simply from the rarity of the contrast.

REQUIREMENTS FOR A WELL LIGHTED WORKSHOP.

Firstly, the light, if artificial, should be sufficiently intense to give the power of clear and natural sight over any portion of the work. For enabling the work to be performed with ease the light should evidently be arranged to produce as nearly as can be the effect of natural sunlight. The light of the sun is diffused by the atmosphere; and unless its entrance is limited in extent, such shadows as it may produce are only natural shadows, so natural that the eye has no difficulty in following detail in any visible part. In this respect, therefore, artificial light should, as far as practicable, imitate the best natural conditions. Secondly, the light should be so diffused as to avoid casting shadows or placing any one portion of the work in too great relief as compared with the general tone of the whole. If the work were being done in front of a window which faced the sun, a certain portion of it would receive an undue amount of light, and give a false idea alike of size and distance, owing to the contrast of the overlighted and underlighted parts. This might be a natural light, but would nevertheless be improper. Thirdly, the light should be of such a character as to have no tendency to injure the sight by a blinding glare. This remark applies either to a good gas-flame or to the electric glow-lamp, from both of which the light is well diffused; the rays, being all comparatively weak, are easily diverted and thus distributed. But the effect of having either a bright gas-flame or the still brighter glowing wire before the eyes is exceedingly fatiguing and destructive to the sight, and in combination with the dust of workshops makes it a wonder that ocular diseases are not more common than they are. Fourthly, the light should be of such a character as to leave the atmosphere free from noxious emanations. Any kind of natural or electric light will fulfil this condition. The artificial light that most infringes it is gas, which varies much from town to town, and even in the same town from time to time; but it is generally so impure as to be deleterious to health and comfort in the products of its combustion, which is always more or less incomplete. Fifthly, the light should not unduly raise the temperature of the room in which it is employed. If, on a hot day, a gas burner has to be lit for every person in a crowded workshop, as has to be done in certain manufactories, the combustion of so much gas affects the temperature greatly, and thereby produces lassitude among the workpeople, together with various ailments which are almost in proportion to the amount of gas consumed. Sixthly, the light should be simple and capable of easy control. The whole arrangement should be so contrived that nothing but the simplest knowledge and experience are required for turning the light on and off. This implies, of course, both a central control and also various points of sub-central control. Seventhly, the cost should be kept within such limits as will render the light practicable at the present day for those who have to make their livelihood in their special trade in open competition with the rest of the world.

ELECTRIC LIGHTING BY INVERTED ARC-LAMPS.

Some years ago, while engaged in visiting and examining certain mills on the Continent, the writer was much struck with a mode of lighting which he then saw for the first time. This consisted in the use of electric arc-lamps of from 1,600 to 2,000 C. P., suspended in a white enamelled reflector at a certain distance below the whitewashed ceiling of the mill. The first he saw was of 2,000 C. P., and thoroughly lighted a large room of about 40 feet square with light sufficient to see to pick up a pin off the floor. The walls of the room, as well as the ceiling, were whitewashed. The light had a sort of bluish tinge, and looked like bright moonlight, but with much greater illumination and entirely without shadows. This appeared so striking that he made a few experiments at once, and found that it was possible to see into the interior of the machines, and even underneath them, in a way that up to then would have seemed incredible; and further, that it was not possible to make a shadow of any description, even when holding a hat only 2 inches above the floor; all that could be seen in the centre of the covered part was a comparatively slight deepening of the shade. In other departments of the factory he found the same plan equally effective, and the diffusion of light so complete as to be astonishing.

INCANDESCENT GLOW-LAMPS.

At that time the author's firm were engaged in replacing gas by incandescent glow-lamps on the Edison-Swan system in a large machining room at their own works, which is 345 feet long by 76 feet broad and only 12 feet high, containing 239 machines tended by 200 workpeople in the area of 26,220 square feet. The exigencies of trade had required that annexes should be constructed almost all round the building, thus further diminishing the amount of natural light that could gain admission. Along the whole of the centre of the shop, for a breadth of some 50 feet, gas was burning day and night; and in the close muggy weather of autumn and the fog-laden days of hot summer the atmosphere of the room became most oppressive, in spite of the best ventilation by Blackman propellers; even at six o'clock in the morning, on entering the room, the smell was most objectionable. It was noticeable, too, that an undue proportion of the men suffered from diarrhœa, which was in fact a standard complaint and furnished the constant explanation for absence from work. Although sometimes this was simply an excuse, there can be no doubt that the exhalations caused by the imperfect combustion of a gas not absolutely pure will suffice to explain the possibility of a large number of men being affected thereby. The incandescent glow-lamps, each with its own switch, and covered with a wire guard, were attached to the gas brackets, which for this purpose were left just as they had been. Within a week of the application of these lamps, the importance of the third requirement, with regard to glare, was amply proved; for nearly every work man had devised a shade of one kind or another, some of white or brown paper, some opaque, and some translucent. No better device than this has been found; it does not look neat, being simply a makeshift; but it answers the purpose, costs nothing, and is applied in a moment. The results of the alteration were curious; the atmosphere was improved, and heat considerably diminished, diarrhœa as a general complaint ceased, and was at first succeeded by bronchitis, which, however, was found to be of a temporary nature and disappeared as soon as the workpeople in that room had become acclimated.

---

[*] Abstract of Paper read before the English Institution of Mechanical Engineers.

Nevertheless with the result of this lighting the author was not satisfied. The shop was as dark and gloomy as with the previous gaslights. The number of lamps broken by accident and by carelessness was so great as to become a serious consideration, their price being out of proportion to their actual cost, and no allowance being made in regard to royalty in replacing broken lamps which had already paid royalty. The writer then made two further journeys to the Continent, in order again to examine the plan of the inverted arc-lamp; and on the first occasion returned more favorably impressed than before. The second journey was therefore made with the view of going more thoroughly into the details, and of concluding arrangements for conducting a trial of the plan in his firm's establishment. On this occasion he had the opportunity of examining a large weaving shed at Ruysbroek, near Brussels, on a dark winter night. The dynamo was driven from the main engine of the mill, and was a fine piece of work. Corridors lighted by incandescent lamps led thence to the vast weaving shed, which had the usual roof containing glass panels almost upright, facing north, with a plastered ceiling sloping southwards from the top of each glazed panel, and lighted from an inverted arc lamp in each bay between the pillars. The impression upon entering the doorway was that the large room was brilliantly lighted by the mid-day sun; no glare, no flames to be seen, but a golden light pervading the whole of the vast enclosure; the color of the hair, complexion, and costumes of the workingwomen perfectly distinct; under the looms not the slightest trace of shadow. In fact the result attained was an absolutely perfect ideal light for textile work. The bluish tinge of the arc light itself, when lighting direct, is more apparent than real, because it does not prevent the most delicate shades of color from being appreciated. If, however, it is considered disagreeable or undesirable, it can be altered, as it was in this particular weaving factory, by mixing a trace of yellow with the ordinary whitewash; the ceiling is then still white, but the apparently bluish tinge is eliminated.

The result of this visit was the application of four inverted arc-lamps in the large low machining rooms at the writer's works. Over 50 tons of castings are daily taken in and out of this room; and there must be at least 300 tons of castings of various sizes and descriptions in progress of treatment stacked and piled in different places on the floor; there is therefore all the more necessity for good lighting in order to avoid accidents. The darkest portion of the shop was chosen, and the four arc-lamps were placed in approximately the best positions for lighting a certain area. The ceiling not being plastered, it was considered advisable to nail up to the joists light scantlings, which were afterwards whitewashed. These lights have now been running almost day and night for about two years, and with unqualified success. The four arc-lamps have replaced twenty-six glow-lamps; but whereas each glow-lamp lighted up its own work only and a few inches around, the whole of the area lighted by the four inverted arc-lamps is bathed in a gentle temperate light, absolutely equal in all parts. This was encouraging, as an arrangement of this description involves a heavy expenditure; and it was therefore considered advisable to have further experience before going largely into it. Moreover, this plan of lighting would not always be applicable. If the ceiling were very low it would scarcely be practicable, because the arc lamp must hang a certain distance below the ceiling and still leave head room. Also there are places where the amount of light required is so small that it would be injudicious to go to the expense of applying these lamps, which are capable of so much more duty. It was determined, however, to make an experiment on a practical scale at the author's works, and with this object to apply inverted arc lamps for the lighting of a three-story building with large attic floor above, the latter being used as an iron and wood pattern-room.

Current Items.

An attempt is being made in London to produce ozone on such a scale that it will be available for innumerable hygienic and commercial purposes. The apparatus used is electrical, the ozonizer consisting of a number of serrated strips formed up into grids and separated from each other by plates of glass. On connecting these grids with opposite terminals of a high potential alternating current, what is called a "brush discharge" takes place on to the glass from the points of the serrations, and the characteristic smell of ozone is quickly apparent. To make the ozone in still greater volume, a large number of these plates are so arranged in a suitable case that when the discharge is established a current of air is passed through the apparatus, whence it emerges heavily charged with ozone. Before the air is passed into the ozonizer it is filtered, cooled and dried, so that its purity is insured.

There is a certain Greek engineer, now resident in Europe, who ought to have been an American, for he is the author of just the kind of scheme that, in the matter of boldness and picturesqueness, the world at large looks to Yankeeland to originate. At various points on the Bosphorus the current from the Black Sea to the Mediterranean has prodigious force, and it is now proposed to harness some of this waste power for the lighting of the whole of the city of Constantinople and a considerable length of the adjacent coast by electricity. The way in which the inventor intends to turn the ocean currents to account is to erect three very powerful dynamo machines upon the three points of the Bosphorus where the current has the greatest force, and, so far as can at present be learned, the project appears to be practical and realizable. It is stated that the company of capitalists has been formed, the necessary funds subscribed and application for a concession addressed to the Turkish Government. It is understood that the Government has taken the project into consideration and has nominated a commission to report on it.

Transformer Diagrams Experimentally Determined.—II.*

BY DR. FREDERICK BEDELL,

Assisted by A. W. Berresford, W. M. Craft and B. Gherardi, Jr.

CONSTANT CURRENT EXPERIMENTS.

The transformer was supplied in these experiments with a constant primary current, the square root of mean square value of which was 9¼ amperes, and the maximum value about 13·2 amperes. The frequency was such that $\omega = 2\pi n = 566$. The transformer was used both as a "step-up" and as a "step-down" transformer. The step-up and step-down experiments were substantially the same, inasmuch as the ratio of primary and secondary turns was small; therefore, in this paper, the results of the constant current experiments will only be given for the step-down transformation. A run was first made with the movable tongue secured in the zero position, that is, in the position in which the reluctance of the magnetic circuit is the highest and the coefficients of induction the smallest. The secondary non-inductive load of incandescent lamps was then varied from short circuit to open circuit and the primary and secondary measurements taken as described for successive values of the secondary resistance. The tongue was then moved in and secured in the 70° position, and a complete set of readings again taken of primary and secondary for different loads. Runs were then made with the tongue secured at 90°, 120°, 150° and all in at 180°, and the same measurements taken.

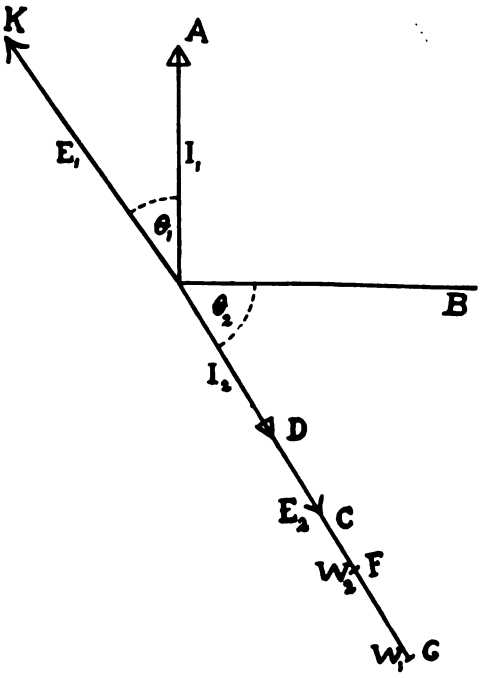

Fig. 4.

In this way data was obtained for all values of the coefficients of induction of the transformer, within the range of change produced by the moving in and out of the tongue, for all values of secondary resistance. For each observation, the primary and secondary currents and electromotive forces were known both in magnitude and direction—sufficient data for the construction of a polar transformer diagram. Such a diagram is represented in Fig. 4.

Polar Diagram.—The lines $\overline{OA}$, $\overline{OB}$, $\overline{OC}$, etc.. represent the maximum values of the harmonic electromotive forces and currents in their relative phase positions. Rotation is counter-clock-wise about o. The instantaneous values of the currents and electromotive forces are equal at any instant to the projection upon any fixed line of reference, of the lines representing the corresponding maximum values. Closed arrows indicate currents and open arrows electromotive forces. $\overline{OA}$ is drawn equal to the primary current, I_1. The primary impressed electromotive force is in advance of the primary current by an angle θ_1, and is represented by the line $\overline{OK}$ drawn to any convenient scale. The electromotive force induced in the secondary due to the primary current is 90° behind the primary current. $\overline{OB}$ represents this induced electromotive force, or the secondary impressed electromotive force. The secondary external resistance is non-inductive and the current is therefore in phase with the electromotive force measured at the terminals of the transformer secondary, but the current and measured secondary electromotive force lag behind the secondary impressed electromotive force $\overline{OB}$ by an angle θ_2 due to the self-induction in the secondary coil. The angle θ_2 is drawn so that $\tan \theta_2 = \frac{L_2\,\omega}{R_2}$. $\overline{OD}$ is drawn equal to the secondary current I_2, and $\overline{OC}$ equal to the electromotive force E_2 at the terminals of the secondary. As before explained, these lines represent maximum values.

---

* Read before the International Electrical Congress, Chicago.

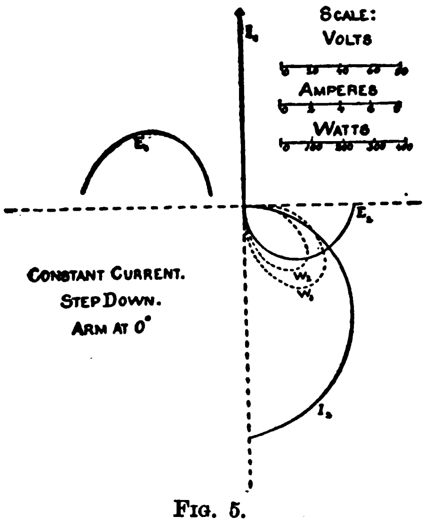

FIG. 5.

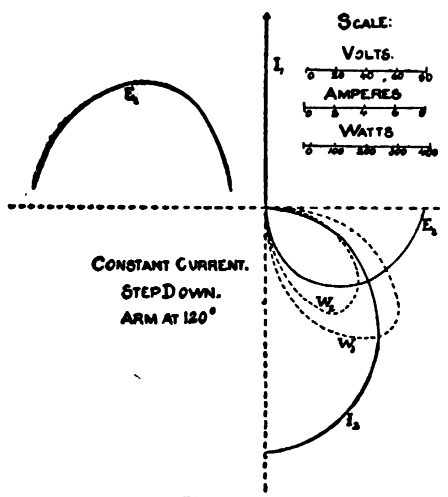

FIG. 8.

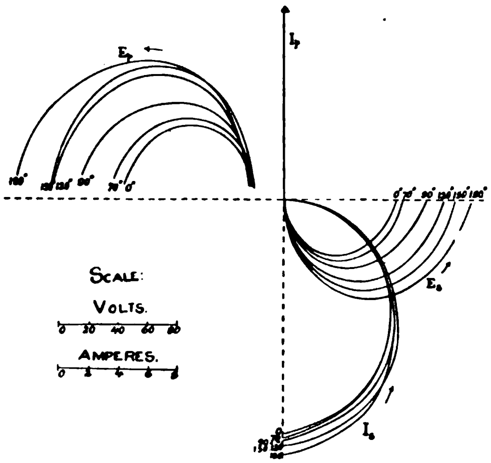

FIG. 11.

The primary and secondary power, W_1 and W_2, although not vector quantities, may for convenience be represented by the lines $\overline{OG}$ and $\overline{OF}$ drawn in the direction of the secondary current.

Diagrams similar to Fig. 4 may be drawn for each load of the transformer, the differences between them showing the effects of the variation of R_2. When these diagrams are superimposed, with the lines $\overline{OA}$ for primary current coinciding, the variations in the different quantities are more readily observed by a study of the locus formed for each of the several quantities, which changes as the secondary resistance is altered. It is in this way that the following diagrams are plotted. Fig. 5 shows the variation in the primary electromotive force, secondary current and electromotive force, and the variation in the primary and secondary power for all loads of the transformer, from $R_2 = 0$ to $R_2 = \infty$, for a constant primary current when the tongue is in the 0° position, that is, when it is all out. The arrows on E_1, E_2 and I_2 indicate the direction of the change as the secondary resistance increases. Figs. 6, 7, 8, 9 and 10 are drawn in the same manner for other positions of the tongue. In all cases the primary current is constant.

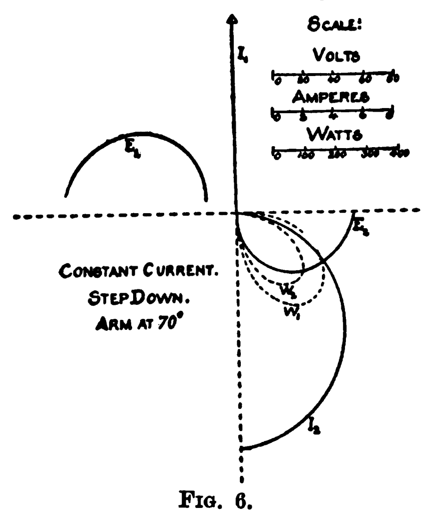

FIG. 6.

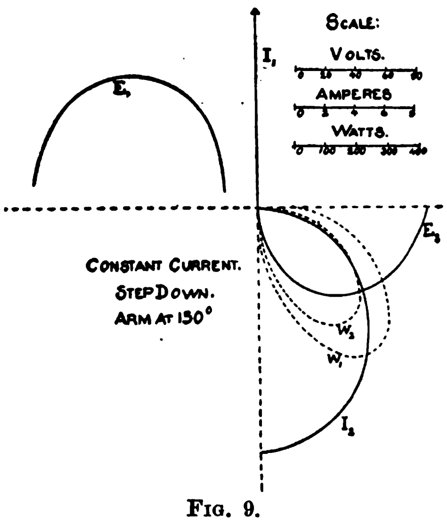

FIG. 9.

The agreement of these curves with the theoretical is noticeable. The primary electromotive force curve, the curves for the secondary electromotive force and current are approximately semicircles, as theory would indicate. The power curves, W_1 and W_2, are symmetrical lobes at about 45°. The shifting of the primary electromotive force curve to the left is caused by magnetic leakage and is also in perfect accordance with theory, as given in the series of articles on the Theory of the Transformer already referred to. The changes in the successive diagrams, from Fig. 5 with the tongue all out to Fig. 10 with the tongue all in, show the effects of diminished reluctance and increased coefficients of induction. The diameter of the semicircle for the secondary electromotive force increases in direct proportion to the increase in the coefficient of mutual induction. The primary electromotive circle increases in proportion to the coefficient of self-induction of the primary. The diameter of the secondary current circle is nearly constant.

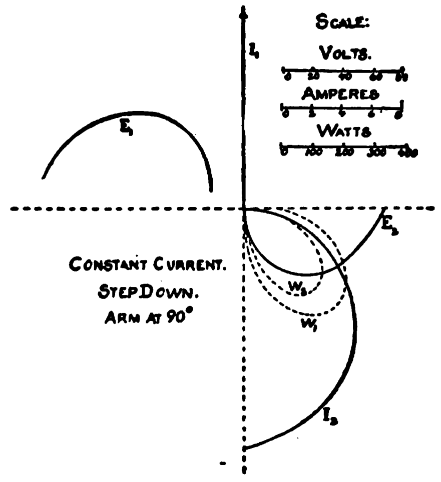

FIG. 7.

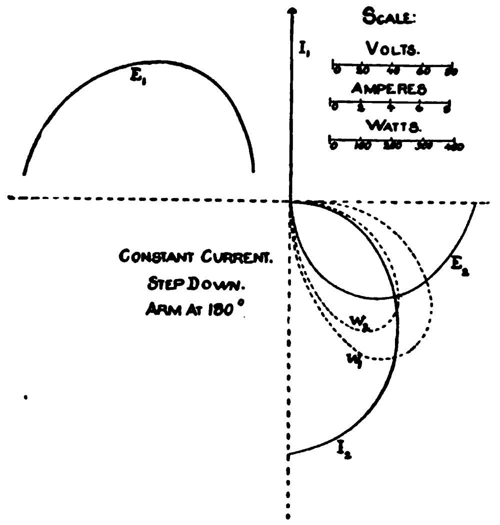

FIG. 10.

The comparison of these curves is better seen in Fig. 11, in which the preceding diagrams are combined so as to show the successive changes in the currents and electromotive forces for different tongue positions. A composite figure is shown in the same way for the power curves, W_1 and W_2, in Fig. 12.

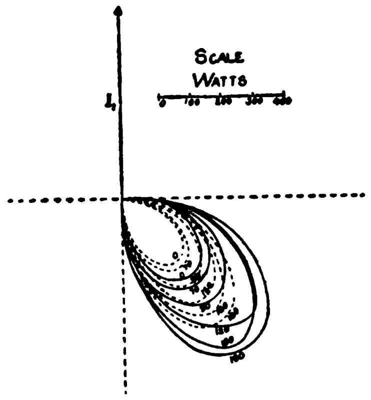

FIG. 12.

(To be continued.)

Niagara Falls, N. Y.—The Pittsburg Reduction Company is the first to enter into a contract for electric power with the Niagara Falls Power Company, engaging 6,500 H. P. The Reduction Company has leased eight acres of land here, and will put up extensive works. The Briggs Manufacturing Company will also put up works here for the manufacture of the Briggs patent press feeder, and will take power from the Niagara Falls Company.

General Electric Rumors.

BOSTON, Nov. 13.—A report reaches us from a source that is usually correct in its statements that the General Electric Company is at last to dissolve and the various companies now in the Trust are to revert to their former status as independent concerns, which is understood as meaning that there would at once be competition, free and open, even with the various concerns which constitute the Trust, most of which have been handicapped beyond endurance, and some of them actually closed up entirely. Another report, and this comes from Lynn, is that the Boston and Maine Railroad Company is trying to secure the Saugus River Works of the General Electric Company to use them as a machine shop, and along with this latter report comes a supplementary one that a rubber manufacturing company is being organized in Lynn, with Mr. C. A. Coffin as president.

Legal Notes.

In compliance with an order of Judge White, Attorney F. B. Skeels made a report in the Probate Court at Cleveland, O., on the 4th inst., concerning his trust as assignee of the W. D. Graves Electrical Manufacturing Company. The cause of the filing of the report was based upon an effort on the part of the Cleveland Electrical Manufacturing Company, one of the creditors, to have the business of the Graves Company discontinued. Attorney Skeels says that he has purchased material to the value of $7,201.75, and has sold manufactured goods to the value of $12,723.09. His expenses amounted to $7.056.82. He has received in cash $11,986.48, and has paid out $12,090.47. The amount of manufactured goods in excess of those included in the inventory of last January is estimated at $1,500.

Another suit affecting the City Electric Street Railway Company of Little Rock has been filed in the United States Circuit Court at Little Rock, Ark. The plaintiff is the Atlantic Trust Company of New York, holder of $300,000 first mortgage bonds of the City Electric Railway Company, and suit is brought to foreclose on these bonds on account of default in the payment of interest. The St. Louis Trust Company hold $300,000 bonds, executed subsequently, and they are made parties defendant, in order that priority of lien may be established; likewise, all judgment creditors are also made parties, including those obtaining damages against the road by reason of accident and resulting injury, over all of which the plaintiff asserts priority of lien.

A preliminary injunction has been granted in the United States Circuit Court restraining Edward N. Fraleigh, of No 26 Church street, New York, from making or using his magneto telephone, the receivers and transmitters of which are said to be an infringement of the American Bell Telephone Company's patent.

The Chester, Pa., Arnold Electric Manufacturing Company, which was closed by the sheriff on the 11th, has made an assignment, appointing Craig R. Arnold, late president of the company, as agent. The Delaware County Trust, Safe Deposit and Title Insurance Company was made assignee.

Status of the Mount Morris and United States Electric Lighting Companies.

An opinion was handed down Monday, the 13th, by Judge Shipman, in the United States Circuit Court of Appeals, in the case of the Edison Electric Light Company against the Mount Morris Electric Light Company and the United States Electric Light and Power Company. Judge Lacombe handed down a decision six weeks ago restraining the Mount Morris and United States companies from using in this city lamps infringing the Edison patents. Judge Shipman reverses this as far as it affects the customers of the other companies taken on prior to the first decision of the courts in favor of the patents. In substance, his decision is that the Edison Company is bound to furnish the defendants with Edison lamps for their business upon reasonable terms.

Mr. Wallace's Resignation.

Mr. John B. Wallace has resigned his position as receiver for the Ansonia Electric Company in Connecticut. The motion for his removal, which was made by creditors of the company, has therefore been dropped. Mr. Wallace's counsel stated to the court that his client did not desire to remain as receiver against the wish of the creditors. Mr. S. S. Mersick, of New Haven, has been appointed to succeed Mr. Wallace.

It is stated that the Ansonia National Bank is the largest creditor objecting to the proposed basis of settlement, and that it refuses to sign.

Buffalo Electrical Society.

The annual meeting of the Buffalo Electrical Society was held a few evenings ago at its rooms in Buffalo. The treasurer's report was read, and showed a balance on hand of $152.88; the librarian's statement showed the library to contain 75 copies of standard electrical works, 66 bound volumes of electrical periodicals and a large quantity of experimental apparatus. President Kitton congratulated the society on having completed its eleventh year of existence and on its success as an organization.

These officers were elected for the ensuing year: President, Philip K. Stern; vice-president, Frank C. Perkins; secretary, Astley C. Terry; treasurer, Samuel Stewart, and librarian, John G. McNerney; executive committee — Frank Kitton, George A. Burnett and C. V. Boughton.

At the next meeting, on November 16, President Stern will read a paper on "Electricity at the World's Fair."

American Institute of Electrical Engineers.

The eighty-first meeting of the Institute will be held at headquarters, 12 West 31st street, New York City, on Wednesday, November 15, at 8 o'clock P. M.

The business of the evening will be the discussion of the report of the Special Committee of the Council appointed at the last meeting on Local Meetings of the Institute.

The committee is composed of the following members of the Council: Herbert Laws Webb, chairman; Geo. M. Phelps, Wm. J. Hammer, A. E. Kennelly and M. I. Pupin.

The Complete Electric Construction Co.

At a recent meeting of the directors of the above company the following officers were elected:

Mr. John A. Seely, president and general manager.

Mr. W. H. Baker, of the Postal Telegraph Company, vice-president.

Mr. C. O. Baker, Jr., of Baker & Company, platinum refiners, secretary and treasurer.

Mr. George G. Ward, of the Commercial Cable Company, and Mr. George F. Porter, secretary of the National Electric Light Association, directors.

Mr. Baker retains his interest with Baker & Company, and his position there will be unaffected by his connection with this company.

A Safe Statement.

The News as It is Given Out in Connecticut.

(From the Boston Advertiser.)

President Dustin, of the Schuyler Electric Company, Middletown, is authority for the statement that the works will be started in full as soon as there are sufficient orders ahead to warrant it.

Trade Note.

Messrs. Taylor, Goodne & Ames, Chicago, have discontinued their agency for Wagner motors, and are now handling a full line of Diamond motors, dynamos, transformers, etc.

General Electric.

Its Stagnation Explained to an Arkansaw Constituent.

To the Editor of ELECTRICITY.

DEAR SIR: Down this way we are all dependent upon your valued and courageous journal for our news in regard to the General Electric Company, and for several weeks you seem to have neglected us in this respect. What is the reason? Have you also, like your contemporaries, been subsidized, or is your fighting editor dead? CONSTANT READER.

Gravelly Hill, Yell Co., Arkansas, Nov. 10.

We will answer the last of our correspondent's inquiries first. ELECTRICITY'S fighting editor is not dead. He has not been knocked out. He has had something over fifty rounds with the General Electric Company, and has not received even a scratch in the scrimmage. But our fighting editor is a true sport. If he were to visit Yell County he would by unanimous consent be called "dead game." He does not believe in fighting after the battle is over, or in the wanton enthusiasm of success waving his fists over the prostrate form of his beaten antagonist, and shouting "Come on, get another!"

ELECTRICITY has not been subsidized. And if devotion to principle were not sufficient to render this impossible, the general condemnation which has been expressed of the course of our milk-and-water contemporaries is the strongest kind of a *business* argument against accepting anything in the nature of a subsidy. ELECTRICITY is *right*, and also *successful*.

The reason we have published little General Electric news of late is that there is little news to publish.

The affairs of the company as it stands to-day are of slight interest to any one except to the careful historians and philosophers who will write long treatises on the "Peculiar Contortions of a Corpse."

The business of the company has sunk to almost nothing, its factories are almost as silent as a graveyard at midnight, and its employees have few duties except attendance upon committee meetings.

There is no head to its affairs, no policy, and consequently no energy. It is like a ship at sea with a discredited captain and broken-down engines.

To go beyond our correspondent's inquiries, and state how the company was wrecked, would be merely to reiterate the facts published in these columns during the past year.

The present condition of affairs, however, cannot continue long, and ELECTRICITY may be relied on to give the news when there is any.

Already Drexel, Morgan & Company are reported to have offered the entire concern to a syndicate for a sum only 25 per cent. above the capitalization of the Edison General Company, but the offer was not acccepted.

The company will be reorganized, and will be conducted upon fair or dishonorable methods exactly in proportion to the thoroughness with which the T.-H. element is weeded out. When occasion demands, our yell will be loud enough to reach even our Constant Reader in Gravelly Hill.—ED.

Bulk Does not Signify Greatness.

(For the instruction of the E—l W—d.)

It is not growing like a tree
In bulk, doth make man better be;
Nor standing long an oak, three hundred year,
To fall at last, dry, brown and sear.
A lily of a day, is fairer far in May;
And though it fade and die that night,
It was the child and flower of light.

BEN JONSON.

Ring Rule at the Institute.

The action of a few of those in power in the American Institute of Electrical Engineers in regard to the disposition of papers presented before other societies, which culminated at the last meeting in the order to print a paper which had never come properly before the Institute, is exciting quite as unfavorable comment among members outside of New York as among those who reside here and are conversant with the facts. We have heard directly and indirectly from a number of members whose membership is valued by the Institute as highly as they themselves have valued it, and their characterization of the proceedings has been that it was high-handed in the extreme. More than one prominent member has stated that if such mistakes are repeated as have in several recent instances occurred in the selection of papers for the Institute and for admission to the Transactions, they will make manifest their disgust by resigning their membership. When men of this calibre speak in such a manner there is certainly something radically wrong, and it behooves us to look about us both for the evil and its remedy. Fortunately for the good of the society the nature of the evil was made perfectly manifest in the proceedings of the last meeting, and its remedy is suggested at once.

There are one or two or three members whose activity in the affairs of the Institute from the beginning has given them a prominence to which their qualifications as engineers have not entitled them so much as have their abilities as organizers, wirepullers and politicians. To them the Institute has been indebted for much of wise counsel, and their preferment has been natural and deserved in a large measure. They have looked upon themselves, however, as leaders, and have been leaders for so long a time that they have become accustomed to dictate the policy of the Institute as did Croker the policy of the Democratic party in New York and McLaughlin in Brooklyn. In fact the position of politics in New York previous to the last election and of politics within the Institute are strikingly similar. Tammany shoved Maynard down the throats of the people in the one case, and another Tammany, smaller in its ramifications, but no less autocratic, by the most unusual proceedings forced a paper belonging to another society into the archives of the Institute. The Institute Tammany will reply that the proceedings referred to were not unusual or contrary to the customs of the Institute. Let us grant for a moment that they were not. If it is possible in accordance with the rules and customs of the Institute that a paper read before another society can be incorporated in its transactions without having been either submitted to or discussed by that Institute, without revision of any kind and without its being known in any way that the copy submitted even in any particular resembled the address delivered before that other society, or that such a measure can be forced through the society on the dictum of one man, supported only by the plea that to reject the paper would embarrass that man—we say if such is possible under the rules as they exist, it is its own best argument that they should be at once changed. But we maintain that the proceeding *was* unusual, and that no change in the rules is required; it is only their interpretation by an unprejudiced and fair-minded presiding officer that is needed, backed up by a healthy sentiment among the members against boss or ring rule. If this were not apparent before, it will become so by reference to the following which transpired at the last meeting. A motion was made to refer the paper in question to the Editing Committee, and the question arose as to the functions of that committee. The presiding officer interpreted them as supererogatory. He stated that they were solely to edit the discussions; that they had nothing to do with the paper itself, as no one would present papers before the Institute if they were to be edited by anybody in the Institute, and ridiculed the idea that any such duties were intended for the committee, or that it was usual for any society to assume for itself such privileges or rights with contributed manuscripts. He also stated in substance that in assuming such prerogative the Editing Committee would be clearly trenching on the vested functions of the Committee on Papers and Meetings.

Did not he *know* that his interpretation of the functions of the Editing Committee was directly contrary to those with which they were originally vested *as shown by the records?* The records state expressly that it shall be the duty of the Editing Committee to *revise* and *edit* papers which come before the Institute.

Did he not *know* that it is universally customary in societies publishing their own proceedings to have an editing committee, either under that name or some other, whose duty it is to scrutinize and revise, and edit when necessary, all papers previous to publication? If he does not, we will call to notice a dozen societies that have such a committee to every one that he can mention that has not.

Did he not know that the Committee on Papers and Meetings did not come into existence until six months after the creation of the Editing Committee, and that the functions of the latter are entirely distinct from those of the former, and that the "trenching," if any, is on the other side? If he does not, would it not be well for him, as the presiding officer, to inform himself by looking up the records? But this is of consequence only in so far as continued ignorance on the part of the presiding officer may result in continued activity of the ring, which knowledge would enable him to squelch at once. According to his interpretation of the functions of the Editing Committee, the motion to refer was absurd, and it received no second. A precedent was established which will be dangerous in the extreme, and all the more so because, by a measure engineered by this same ring and thoughtlessly supported by many others who did not understand its full import at the time, all record of protest against this high-handed proceeding has been expunged from the minutes. As an immediate result, it may be in order for the Committee on Papers to deny space in the Transactions to all written discussions of the paper, and for the New York Electrical Society to demand for its own members copies of the papers in question, printed at the expense of the Institute. Thus far we have discussed this matter without reference to the intrinsic merit of the paper. We are willing to assume that that was all the most critical could wish, but the Institute does not know this yet, and will not until it is printed in the Transactions. But there have been numerous instances before of the acceptance of papers totally unfit for, or inappropriate to, a publication such as that of which we speak. That such has been and is possible lies not so much in the *personnel* of either the Committee on Papers or Editing Committee, for both of them contain men who have the confidence of the Institute, but rather in the fact that power has been usurped by men who have neither the qualifications nor the abilities which entitle them to sit as censors in such important matters. In fact, a single individual has so far assumed these duties as to make it appear almost presumptuous for those to whom they were originally delegated to raise their voices in opposition, and they have lapsed into a state of innocuous desuetude. When heretofore papers of an improper character have been read before the Institute, we have purposely withheld criticism in these columns, feeling that their discussion by the members of the Institute would be the proper remedy. This has not, however, proved to be the case, for every paper that has been read has been published simply on the dictum of the Institute Tammany. But now when this ring removes even this last safeguard, viz., the free discussion of all papers offered for the Institute's consideration—when it arrogates to itself the right to over-ride all sense of propriety, and to muzzle those who have an unselfish interest in the welfare of the Institute—it is high time for the members to assert themselves, for by so doing alone can the dignity of the organization be maintained. No one can contribute to this desirable consummation more ably than can its honored president by breaking away from the influences of which we speak and observing a strict neutrality even though it do violence to personal obligations. But the members themselves have a duty to perform in upholding his hands in such endeavors, and insisting in no uncertain terms upon a strict scrutiny of everything that is destined for the pages of the Transactions. We believe the duties of the committees are properly distributed, and sufficiently explicit and defined, but have been usurped. It only needed an incident such as the Maynard incident in New York politics to arouse the people to action. We hope that the incidents of the last meeting of the Institute will have been sufficient to in like manner arouse its members from their lethargy. If so, they will have proved a blessing in disguise.

Those members residing in New York or in its vicinity who fail to attend the monthly meetings of the Institute are to a considerable extent responsible for the present turn of affairs, for the reason that their personal influence, if present, as well as their votes, would lend its proportional weight in the decision of questions which come up at these meetings. In order to maintain the standard of the society at the highest rank, it is essential that every member should, as far as possible, fulfil the duties which his membership involves, and the failure on the part of representative members to take an actual interest in the affairs of the Institute must inevitably result in its deterioration.

The most emphatic condemnation of a poor paper would be its exposure in the discussions, and impartial criticism is the most effective method of discouraging the presentation of trivial or inferior papers, but if these are allowed to pass unchallenged, their acceptability is thereby tacitly acknowledged.

The American Institute of Electrical Engineers has attained the position of the representative electrical society of this country solely on the merits of its previous career, and any tendency toward its deterioration cannot but be deplored; but this result can only be averted by the participation of its worthiest members in its affairs, and by selecting from among them officers whose ability will be a guarantee of their efficient management.

……o……

Steam vs. Water Power. The question of the utilization of water power, which has been brought prominently to public notice by the great Niagara project, is the subject of a communication from the United States Consul at Switzerland, where water power abounds and has been extensively used as a source of power. The figures given in this report are far from being unfavorable to water power under some conditions, and in the absence of any details they are difficult to criticise, but the fact that power procured from this source and transmitted three miles is said to cost nearly three times as much per horse power per annum as that generated by steam in England is sufficient to make the statement of interest. The most disadvantageous conditions can hardly account for such an excessive difference in the cost of power generated by these two methods.

The report contains a table recently published in Chemnitz—by whom is not mentioned—giving the relative cost per horse power of producing 50, 300 and 500 horse power in England, Germany, Bohemia and Switzerland as follows:

	50 H. P.	300 H. P.	500 H. P.
England……….	$24.24	$12.58	$9.88
Germany……….	29.21	15.52	13.51
Bohemia……….	27.50	14.74	12.97
Switzerland…….	46.82	29.61	25.54

The relative cost of producing the same from a waterfall is given at the source of supply as $30.88, $16.98 and $12.54 respectively, for 50, 300 and 500 horse power plants, but by adding to these the cost of an electric transmission of about three miles, the totals reach $57.68, $31.27 and $25.48.

It is stated also that the necessity often exists of holding a steam plant in reserve on account of the failures of the hydraulic and electric plants due to freshets, icy winters, mountain storms, etc., but where the power has been used for twenty-four hours a day, and supplies lighting at night, water power shows an advantage over steam.

From an American standpoint these figures for the cost of water power and electric transmission are about what might be expected, and agree very closely with the conclusions of Dr. Emery, published in ELECTRICITY, Vol. IV, No. 2, but some of the figures given as the cost per horse power with steam plants are so incredibly low as to leave much doubt as to their accuracy.

On the basis of ten hours a day in this country the operating expenses and interest charges per horse power alone on a 500 horse power plant, without making any charge for coal whatever, are nearly double the total cost per horse power named for the same size plant in England, which makes it more than probable that the figures for the different countries given in the table include certain factors only and are not true totals.

The report in general is intended to convey a warning against the inconsiderate adoption of water power for every class of work, and to refute the idea that a waterfall is necessarily the cheapest source of power obtainable. It points out, on the other hand, the fact that under certain conditions this motive power may prove a great saving over a steam plant, and in this way suggests the importance of carefully weighing the conditions of every case before deciding between the two methods.

Where a waterfall is available as a motive power, a careful comparison of its annual cost of operation and interest charges with those of coal or other fuel is necessary to determine their relative values in any locality. The first point of importance is the certainty and adequacy of the water supply. There are probably but very few places where it is necessary to keep a steam plant in reserve to supplement or replace the water power that the use of the latter will prove of any advantage; certainly not where coal is moderately cheap. Where the water supply is ample the interest on the first cost of both the hydraulic plant and the transmission plant, besides their operating expenses per year, remains to be compared with the corresponding expenses of a steam plant located at the point of consumption of the power. This should include, of course, the efficiencies of both systems.

In some parts of the West, where coal is very scarce and commands an exorbitant price, there would be no question between it and a water power. In such cases the decision rests entirely between the cost of the power delivered and its value at the point of consumption.

The use to which the power is to be applied cuts a very large figure in the decision between water and steam power, which depends upon the electrical transmission plant. The transmission of *current* even over great distances for lighting is one thing, and the transmission of *power* is distinctly another. The former is an accomplished fact, and plants of this character have reached a high efficiency. Considerably over 90 per cent. of the current transmitted can be utilized, and for this service water power has proved its special adaptability and will usually far outrival steam in economy.

The subject of general transmissions for both lighting and power distribution is far more complex than the former one and still remains to be satisfactorily solved.

Considerable of the current electrical literature might be construed as a contradiction of this statement, but in spite of the progress in this direction, on paper, we are still without a comprehensive long-distance transmission plant for general light and power distribution in this country.

The Niagara project, which is confidently expected to throw much light on this subject, will furnish our first experience in this line; and in this respect about the same conditions obtain abroad. Without disparaging the systems which have been proposed for distant power transmission, it is only fair to state that none of them which contemplate furnishing power applicable to every ordinary demand as well as light has been tested under actual commercial conditions, so that their commercial efficiency could be determined.

The work which has been done heretofore in the line of long distance power transmission has been designed to meet the requirements of special cases only, and where water power is utilized for these plants the economy of the system depends almost entirely upon the way in which the power is employed and the number of hours per day it is in use. As almost all such plants have been equipped with simple alternating current machines up to the present time, their success or failure is determined by the adaptability of synchronous motors to the work required.

Where the power is delivered at the transforming station to a main shaft carrying a moderately uniform load throughout the day, this system attains a fair efficiency and will often surpass a steam plant in economy. On the other hand, a widely fluctuating load, or intermissions in the work requiring frequent stopping and starting of the machinery, would almost unquestionably condemn the plant as a failure. In either case, if the current can be utilized for lighting after shutting down the power plant it will add to the profits of the system, but the fact that a special starting device must be used with synchronous motors, which in order to develop torque must be brought into unison with the generators, effectually precludes their use for general power distribution.

The adoption of water power is therefore neither to be advocated nor rejected without the most careful consideration of the special conditions surrounding it, and especially with respect to its annual cost in comparison with that of any other motive power with which it may come into competition.

The efficiency of the hydraulic station and the current transmission are readily determined, so that for lighting purposes the problem is simple, but the efficiency of a further transformation of the electrical energy into mechanical energy will vary between wide limits in different cases.

The development of multiphase currents it is expected will establish light and power transmissions on equally certain grounds, but until this is accomplished the use of waterfalls for distant power will be attended with many contingencies.

The Practical Measurement of Alternating Currents.

Dr. Fleming, in his course of Cantor lectures, gave a valuable discussion on alternating current "energy," and alternating current "quantity." The lecturer first approached the problem of the energy supplied to non-inductive circuits, and then examined the more complex case of inductive systems, such as the primary circuits connected with alternating current stations.

Instruments for the measurement of alternating current energy, or quantity, he classified into "ampere hour meters," and "watt hour meters." In their simplest form they could be called "graphic ammeters" and "wattmeters." The Holden ammeter and the Mengarini wattmeter were examples. In these instruments an arm, carrying a pen, is placed over a paper-covered drum, which is revolved uniformly in twenty-four hours by a clock. The motion by which the pen is displaced is regulated by a part of the instrument which is simply an ammeter or a wattmeter; the extent of movement of the pen is, at any instant, proportional to the current or the power passing through the measuring part at that time. When, therefore, the diagram is cut off and unrolled, there is found on the paper a curve, which represents by its ordinates the power at any instant; and if the whole area of the curve is integrated, then such area represents the total energy or "quantity" which has passed through the meter in twenty-four hours. These instruments have, therefore, the practical advantage of recording two functions at once; they serve the double purpose of indicating the instantaneous current or power, and the total current, quantity or energy. They have, however, the disadvantage that they are not self-integrating.

Next in order of simplicity are the self-integrating ammeters and self-integrating wattmeters. Of the ammeters of this class, one of the simplest is the well-known Shallenberger instrument. This is, however, available only for the measurement of alternating current quantity. The Shallenberger meter consists of a small transformer, one coil of which may be called the primary; this is in series with the circuit in which the current to be measured is flowing. The core of the transformer consists of a little soft iron disc, which is capable of revolving on an axis. This axis is geared at the top with a counting mechanism which records the number of revolutions of the disc; at the bottom there is a vane or fan of aluminium, which serves to retard the rotation of the disc. The secondary circuit of this transformer consists of a small coil of copper which is closed upon itself, and which is placed with its axis inclined at 45° to the axis of the primary coil. When the primary current flows through the primary coil it does two things: it magnetizes the core, and it induces a secondary current in the closed secondary circuit. It is not difficult to show that the phase of this secondary current must be about 90° behind the phase of the primary current, also that the magnetism of the iron core, which is in a direction at right angles to the plane of the primary coils, also lags in phase behind the primary current by about 90°. The magnetism of the core and the induced secondary are therefore in step, and are in such directions that the axis of the disc is always being pulled round by the induced field of the secondary coil. If, then, there were no friction of any kind, the iron disc would be continually accelerated in speed; but, since the air friction varies approximately as the square of the velocity, and since the mean driving force is proportional to the mean square of the current strength, it follows that the total number of revolutions which the disc makes in any time is proportional to the total mean quantity or ampere hours which have passed the primary circuit. The meters can, therefore, be calibrated for a constant in such a way that they read directly ampere hours, and if the pressure between the mains is invariable, they may be graduated to read in Board of Trade units. These meters are very simple to construct and very fairly accurate in performance; they have, therefore, come into extensive use. The velocity of the disc being, at any time, proportional to the mean current passing through the meter, it is possible, if the current is kept tolerably constant, to employ the instrument as an ammeter. By moving the position of the secondary coil, a little adjustment can be made in the meter for change of frequency; so that the instrument can be calibrated for the particular frequency for which it is intended to be used. The 10 ampere meter starts with less than half an ampere and reads up to 10 amperes. The greatest variation in accuracy, within the limit of reading, is about 3 per cent. The meter has therefore a range of about 1 to 25, and, with care in adjustment, can be made to read more accurately than the above mentioned figure.

The next in order of simplicity, and very similar in principle to the Shallenberger instrument, is the Wright-Ferranti meter. This is also a self-integrating ammeter; it measures, at any instant, the mean square current, and gives the mean quantity which is passed through the meter. The indicating part consists of a wheel with a light iron rim, which is nearly embraced by two curved horns of laminated iron. These horns spring from the corners of a rectangle of laminated iron, which is wound over, on all four sides, with two coils of wire. Through one of these coils the current to be measured passes; the other coil is a shunt coil, the function of which will be described below. The arrangements of the coil are such that at any moment the ends of the curved horns are oppositely magnetic poles. Copper rings are placed upon these curved horns. When the alternating current passes through the series coil it creates alternating magnetism in the curved horns, but owing to the eddy currents set up in the embracing rings, the magnetic lines of force are thrust outwards, making a lateral leakage field, which travels up the horn. This leakage field induces eddy currents in the iron disc which is thereby repelled in virtue of the electro magnetic repulsion between the horn and the wheel. To illustrate this repulsion, Dr. Fleming exhibited a large alternating current magnet, across the top of which he placed a laminated iron bar, embraced at intervals with copper rings. Near to the iron bar he held a soft iron disc, mounted on a pivot, which began to revolve rapidly as soon as the alternating current was set in action. This could be explained by saying that there were a series of alternating magnetic poles running up the iron bar, and that these alternating poles induced other poles in the iron of the disc, which was thus pulled round.

In the Wright-Ferranti meter, the axis which carries the wheel has upon it four aluminium or mica vanes, and was also in connection at the top with a counting mechanism. When an alternating current is passed through the meter, it tends to drive the wheel round with a speed which is proportional to the mean square strength of the current; and, therefore, it follows that the number of revolutions made by the wheel in a given time is proportional to the mean quantity in ampere hours which has passed through the meter at that time. A 20-ampere meter starts with a current of about half an ampere, and reads up to 20 amperes. Within these limits, the greatest deviation in accuracy is only about 1·8 per cent. Both the Shallenberger and Wright-Ferranti meters require to be calibrated for the particular frequency for which they are to be used, and they only give Board of Trade units provided that the pressure between the supply mains is kept constant. The meter reads quantity directly, but power only on the assumption of constant pressure.

Reference was made above to the fact that there were upon the electro-magnet two coils, and that one of these constituted a shunt circuit. The function of this shunt is to supply the driving force which overcomes the friction of the counting train. If this circuit were not present there would be a frictional resistance to be overcome before the meter would start at all.

Another meter, of a simple character, also intended for measuring ampere hours, is the windmill meter, invented some years ago by Prof. Forbes. In this instrument there is a coil of wire which is heated as the current passes through it, thus generating an upward current of air, which is made to rotate a very delicately constructed windmill with mica vanes. The counting train attached to the mill records the number of turns made in a given time. Although this might have seemed a somewhat unpromising principle to apply, the meter itself gave good results.

The second class of meters are the watt hour meters, which are self-integrating. These again may be sub-divided into "continuously" and "intermittently" integrating instruments. Taking the last class first in order, it is well represented by the Frager meter, in which there is a *wattmeter part*, which measures at any instant the power and the *integrating* part, which integrates at intervals the power and the time. The wattmeter part has two coils, a thick one, which is a series coil and a shunt coil, which is movable, being suspended by a steel wire. Attached to the movable shunt coil is a long arm, the displacement of which varies with the power passing through the instrument. Adjacent to the wattmeter, and fixed on the same base, is an electrical clock which drives a curved plate of metal, technically termed the "snail." On the end of the long projecting arm is a small steel point; as the snail is turned round, it passes underneath the arm, and, if this arm is displaced, the length of the path of the pointer when traveling over the snail is proportional to the power passing through the wattmeter. The snail plate is pressed down as the pointer passes over it, making an engagement between the snail and the counting mechanism. At each revolution of the snail the counting mechanism moves through a number of revolutions proportional to the mean power or watts passing; hence, the total number of revolutions in any given time is proportional to the watt hours recorded by the meter. The period of the snail is about three minutes, and hence the record is, as it were, the summation of the power and time increments passing through the wattmeter made at intervals of three minutes. If the current which is to be measured does not vary very rapidly, such an intermittent recording meter may be made to give very accurate results, but there are many cases, as in theatres, where the amount of current is very irregularly and rapidly varied. Under these conditions the wattmeter needle is thrown about in such a manner that the actual power recorded on the dials at every revolution is not always the true mean power passing in the interval between two revolutions, and the readings of the meter may, therefore, become very erroneous. Practice has confirmed these interferences, and although the Frager meter is under some conditions of use a very accurate instrument, there are other conditions under which its readings cannot be depended upon.

(To be continued.)

Dr. W. E. Sumpner has been appointed head of the electrical department of the Battersea (England) Polytechnic Institute.

Fire Losses.

The power house of the Mansfield, O., Electric Railroad Company was partially destroyed by fire on the night of November 8. Two new boilers had been placed in the engine room, and they were ruined by having water thrown on them while red hot. Loss, $7,000; partially covered by insurance.

The porcelain buildings of the Peru Electrical Manufacturing Company have been totally destroyed by fire. Loss $10,000. A large quantity of valuable dies, which were in daily use, all machinery and manufactured and raw material were ruined.

Russell Harrison to be a Street Railway Magnate.

Mr. Russell Harrison's New York syndicate, which has held an option on the Terre Haute, Ind., Electric Street Railway for six months, has secured the property, and Mr. Harrison, as president, has taken charge of the railway. The price is about $750,000, which includes a bonded debt of $600,000. It has about twelve miles of track. The capital stock is $200,000, of which $67,000 is paid up. The road was owned by three Terre Haute men, who, it is said, clear $225,000 on their four years' investment.

General News.

What is Going on in the Electrical World.

St. Paul, Minn.—The St. Paul Electric Manufacturing and Construction Company has made an assignment to E. Yanish, secretary of the St. Paul Barrel Company.

Mascoutah, Ill.—The stockholders of the Mascoutah Electric Light Company have decided to issue $5,000 in bonds for the purpose of raising money to build a new power house.

Spring City, Pa.—The council has given a franchise for an electric street railway to the Schuylkill Valley Illuminating Company. The road will run from Valley Forge through Phœnixville to Spring City.

Hillsdale, Mich.—The electric light war in this city has been settled by the city buying the plant, etc., of F. W. Stock, paying him $10,000 in the bonds of the city therefor. The city is to take possession of the plant November 15.

Los Angeles, Cal.—The Board of Public Works has recommended the granting of a franchise for a street railway on Boyle Heights to W. H. Workman and T. D. Hoskins. The franchise is for fifty years. It is proposed to use the Hoskins electro-vapor motor on the road.

Albany, N. Y.—The Consolidated Car Heating Company has transferred to an English syndicate the English steam and hot water heating patents of the Consolidated Company. The English electric heating patents have not yet been taken by the English syndicate, although it has an option thereon until January 1, 1894.

Janesville, Wis.—Arrangements have been made for lighting Janesville by an electrical current brought from Fulton, fourteen miles away. If the experiment proves a success, it is stated that enough electricity will be generated at the Fulton water power to light all the towns in Southern Wisconsin.

Eau Claire, Wis.—The National Electric Manufacturing Company's plant was sold on November 1 by Ralph E. Rust, receiver, to Peter Truax, of Eau Claire, for $7,500. He was the only bidder. The plant was valued last May at $81,000, but recently appraised at $32,000. Mr. Truax intends to operate it.

Bloomfield, N. J.—The Citizens' Light and Water Committee have made a report recommending the erection and maintenance of an electric light plant by the township. The cost of erecting and equipping a plant that would supply 140 800-candle power arc lights was given at $27,968, and the annual cost of maintenance $6,368.

Indianapolis, Ind.—By the end of the season the only mules left on the Citizens' Street Railroad's system will be the Haughville, Blake Street and Brightwood. The Citizens' Company during the past year has reconstructed and equipped with electricity their roads on as many as fifteen streets and avenues in the city and suburbs.

Columbus, O.—The Columbus Street Railway Company has complied with the law requiring cars to have a vestibuled compartment for the motorman to protect him from the blasts of winter and enable him to attend to his duties in comfort. In other cities of Ohio the street car companies are disposed to test the constitutionality of the law in the courts.

St. Louis.—The Municipal Electric Lighting and Power Company has been formally absorbed by the Edison Illuminating Company, the deeds completing the transfer having been placed on file in the Recorder's office last week. Shortly afterward the new corporation filed for record a deed of trust to the Knickerbocker Trust Company of New York for all its property to secure $4,000,000 worth of bonds. The latter document discloses the fact that the Edison Company owns 5,930 of the 20,000 shares of the Missouri Electric Light Company.

Greenfield, Mass.—A number of local and Boston capitalists and manufacturers are looking up a valuable water power privilege in the town of Conway which is capable of supplying power to a number of large manufacturing plants at a small cost. The scheme is greatly helped by an almost natural dam across the valley through which the South River flows into the Deerfield River. Four hundred and fifty feet below the dam it is proposed to put a power house for the generation of electricity. In the short distance the fall from the top of the dam to the water wheels would be 198 feet, and at the head of the new pond is another natural fall of thirty feet, an additional gain of height and power. It is believed that the storage capacity and watershed would, even in the dryest season, supply 2,000 H. P.

New York.—The Second Avenue line is being equipped with storage batteries, the company, after prolonged tests of the Waddell-Entz system, feeling satisfied of its practicability. Several storage battery cars are now running on the line from Astor Place to 129th street. The company has been operating storage battery cars between 129th and Ninety-second streets since May 1. At 127th street there is a plant with a capacity for serving eighteen cars. With the plant working at full capacity the cost of operating each car per mile is only 5.29 cents. The batteries, consisting of 144 cells for each car, are stored in heavy boxes under the seats of the cars. Each battery has a capacity for forty miles and is of fifty horse power, but each car is supplied with a fresh battery every round trip, the change requiring only four minutes.

Rochester, N. Y.—The statement that electricity as a motive power on the Erie Canal would not be tried this year appears to be unfounded in fact, as it is announced from the office of the Superintendent of Public Works that the Westinghouse Company will at once begin a trial on the Pittsford level, near Rochester. The Rochester *Herald* of the 6th inst. has the following: "On the Erie Canal at Pittsford Saturday will probably be launched the first electric canal boat ever used. In the early forenoon State officials, officers of the Niagara Power Company, and of the Westinghouse General Electric Company will arrive by way of the West Shore to witness the experiments. George Forbes, the noted English electrician, and Nicola Tesla, the great Hungarian electrician, will also be present. The paraphernalia for equipping the plant has already been shipped from the manufacturer at Pittsburg, and together with the boat to be used will be shipped from Buffalo by canal to-day."

Utica, N. Y.—The City Council has passed a resolution directing the clerk to "advertise for proposals to light the city by electric arc lights of 2,000 candle power for 365 nights per year on an average of ten hours per night, at a stated price per light per night, for a term of one year, two years and three years each from January 1, 1894, towers 125 feet high, mast arms and pole lights to be used at or near points where towers, mast arms and poles carrying lights are now located, and for such lights as the mayor and aldermen may deem necessary at the proposed price per light per night, such lights not to exceed 450 during the continuance of this contract. Proposals shall be accompanied by plans showing towers and mast arms proposed to be used; also accompanied by a certified check in the sum of $5,000 that the contractor will perform his contract, said check to be retained by the city clerk until January 20, 1894, and in case of the failure of the contractor to enter upon the full performance of this contract, said sum to be forfeited to the city; sealed proposals to be received by the Common Council and left with the city clerk or mayor of the city on or before November 17 next, at 7:30 P. M., the Common Council reserving the right to reject any and all proposals. The contractor shall give bonds in the sum of $40,000 for the faithful performance of the contract."

Boston Notes.

A report has been in circulation for the last few days that a $2,000,000 contract for apparatus had been secured by the General Electric Company, the filling of which would start up the Lynn factories throughout at full blast. Of course such a report promptly raised high the hopes of everybody hereabouts and in Lynn. But the report was lacking confirmation, so some one took the trouble to ask Prof. Thomson himself, and received the reply that he for one had not heard of any such contract falling into the lap of the company, so for the present the roseate report has to be regarded *cum grano salis*, like most other reports anent the affairs of the General Electric Company which have been published for some months past.

Work on the Interstate Railway, an electric system forty miles long, to extend from Attleboro, Mass., through Pawtucket and Providence to Bullock's Point, R. I., has been suspended for some time past, but is likely to be resumed, and within a few days the entire project may probably be absorbed by the United Traction Company, which owns the Providence and Pawtucket railway systems. Negotiations are in progress, and everything points to a speedy consummation of the undertaking. It has been thought for some time past that it was only a matter of a few months when every street railway in Southern New England would be absorbed by the United Traction Company, and so placed under one general management. The Interstate Company has about twenty-four miles of track in operation already, and the work of extension will be rapidly pushed if the deal goes through.

The City Council of Lynn has under consideration a petition from the Woodward Underground and Electric Company of that city for authority to put underground in its own special type of conduit to the extent of from one to three miles, whereby it shall demonstrate that the Woodward is the best underground conduit on the market for electric wires. Great interest is being taken in the movement in Lynn by the authorities and citizens generally.

Next Thursday evening Professor Elihu Thomson gives a lecture in Odd Fellows' Hall, Lynn, on "The Phenomena of High Potential Currents," which will be illustrated by means of the apparatus that was shown at the World's Fair as Professor Thomson's personal exhibit.

The Edison Electric Illuminating Company is busy laying underground cables from its new central station on Atlantic Avenue out to South Boston by way of Congress Street Bridge, a brisk demand for light and power service having sprung up in that part of the city.

The improvement in the electrical business which we have noted in our columns the last few weeks steadily continues, and as orders come in more freely so the spirits of those receiving them rise proportionally. There is a feeling of greater confidence all round, and while the season has considerably advanced, there are hopeful signs that the worst is past, and that a fair trade will be done through the winter.

Interest in the course of lectures now being given at the Massachusetts Institute of Technology by Prof. Charles R. Cross continues to grow. A large audience of cultivated men and women assembles in Huntington Hall every Monday and Thursday evening to enjoy Prof. Cross's lucid exposition on the subject of "Modern Uses of Electricity," a condensed report of the first two of which we published in our last issue, continuing our reports in the current issue of ELECTRICITY.

The movement in favor of the city of Newton possessing and operating its own electric light station is growing rapidly, and indications warrant the belief that such an undertaking may ere long become *un fait accompli*.

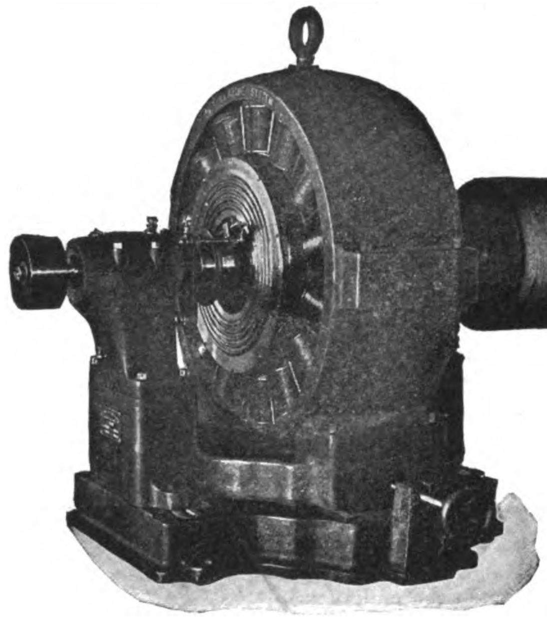
A rich Philadelphia syndicate has purchased the Dixwell Avenue Street Railway, New Haven, Conn., and will entirely remodel it and extend it to Hamden, three miles beyond its present limits. The purchase money is said to have been $200,000, and the entire system will be at once equipped with electricity.

It is reported that the General Electric Company is about to adopt the three-phase electric current system at Tariffville, Conn., for long distance power transmission This is about the largest power transmission plant in New England, and the General Electric and Thomson-Houston Electric Companies have been at work on it for over two years.

With the arrival of the season of the year when electric railway building practically ceases throughout the country, the manufacture of railway apparatus at the General Electric Company's factories at Lynn has slowed down considerably, and only those men absolutely required for filling pressing orders, which are few, will continue at work.

The LaRoche Electrical Works.

The constantly growing demand for larger units in electrical work, and the success which the LaRoche Company has met in the installation of its alternating and direct current apparatus during the past year, has necessitated a very great enlargement and extension of its factory and office facilities in order to handle comfortably the increasing business.



2,000 LIGHT LA ROCHE ALTERNATOR.

The president and general manager of the company, Mr. F. A. LaRoche, so well known to the electrical fraternity, is kept very busy watching its numerous interests, for even through the extremely dull summer season the factory has been running continuously, some large orders have been taken and much prospective work has been estimated upon. Additions to the engineering force of Geo. W. Bacon, of the Wightman Electric Railway Company, and Frank R. Ford, formerly Chicago agent of the Short Electric Railway Company, have recently been made, while Geo. S. Loutey, general construction superintendent for the company, still oversees the installation and operation of the apparatus. The company is also represented by selling agencies at St. Louis, Boston, Pittsburg, Cincinnati, Mobile, Knoxville and San Francisco, and is establishing district agencies in New York and Chicago.

The new works, consisting of a spacious six story brick building, located on the Philadelphia and Reading Railroad at American and Diamond streets, Philadelphia, are well calculated to meet every requirement for the prompt handling of the large alternators and generators which are now being built, for while having the advantage of the best and most convenient shipping facilities, there has been no expense spared in equipping the factory with the most complete and modern machinery, all of which is driven directly, without the intervention of intermediate shafting, from the slow speed automatic LaRoche motors distributed through the factory.

Many special machines have also been added to the factory equipment, by means of which the entire machine work, assembling and final testing can be completed with practically no handling or moving of the heavy castings.

The accompanying illustration shows the 2,000 light pattern of the LaRoche alternator embodying all the most recent improvements. The electrical design of these alternators, both of the single and two phase types, is such that while maintaining a practically constant potential from no load to full load, the iron losses have been reduced to a minimum, and by means of the greatly diminished air gap and close proximity of the armature coils to the magnetic circuit the electrical efficiency has been increased. The copper on the armature is said to be probably less than that of any other alternator on the market of equal output, for by an improved method of winding and placing the armature coils, it has been found possible to entirely do away with the so-called "dead" wire on the armature.

Another novel and vital feature of the LaRoche alternator, which cannot but interest every central station engineer, is the method of connecting the armatures, by which the potential between the different coils is greatly reduced below the total E. M. F. developed by the dynamo.

Mechanically, the design of the alternator is so proportioned as to render it remarkably stable and firm upon the foundation, but capable of perfect adjustment by means of heavy cast-iron sub-bases provided with a belt-tightener. The machines are provided with large self-oiling and self-aligning bearings of the ball and socket type, well rabbeted, and provided with an automatic overflow, with brass rings for securing a continuous lubrication. Another feature, the construction of the brush-holders, will prove highly advantageous where it is required to suddenly lift the brush from the collector. Other details of construction have been perfected to meet the practical requirements of alternating current distribution, so that after a trial of six years, during which time they have undergone modifications and readjustments, the LaRoche alternators embody what practical experience has undoubtedly dictated to be the best for this field of work.

The Non-Infringing Buckeye Lamp.

The Buckeye Electric Company are feeling the effects of a well-established reputation in the rush of orders they are receiving for their non-infringing "Buckeye" lamp. They expect to increase the present output up to 3,000 lamps per day by the first of December; their business winning combination, viz., the coiled filament, perfect vacuum, pure white light, low cost of operation, fair prices and fair dealing, will be perpetuated. The sale of one million "Buckeye" lamps is purposed during the coming year.

A Commutator Preserver.

The commutator preserver illustrated below is a very excellent article and will pay for itself many times over if attached to commutators using either copper or carbon brushes. It does away entirely with the use of oil or other greases and enables the dynamo tender to keep his machine always in a cleanly condition, and it will add at least 50 per cent. to the life of the brushes and commutator.

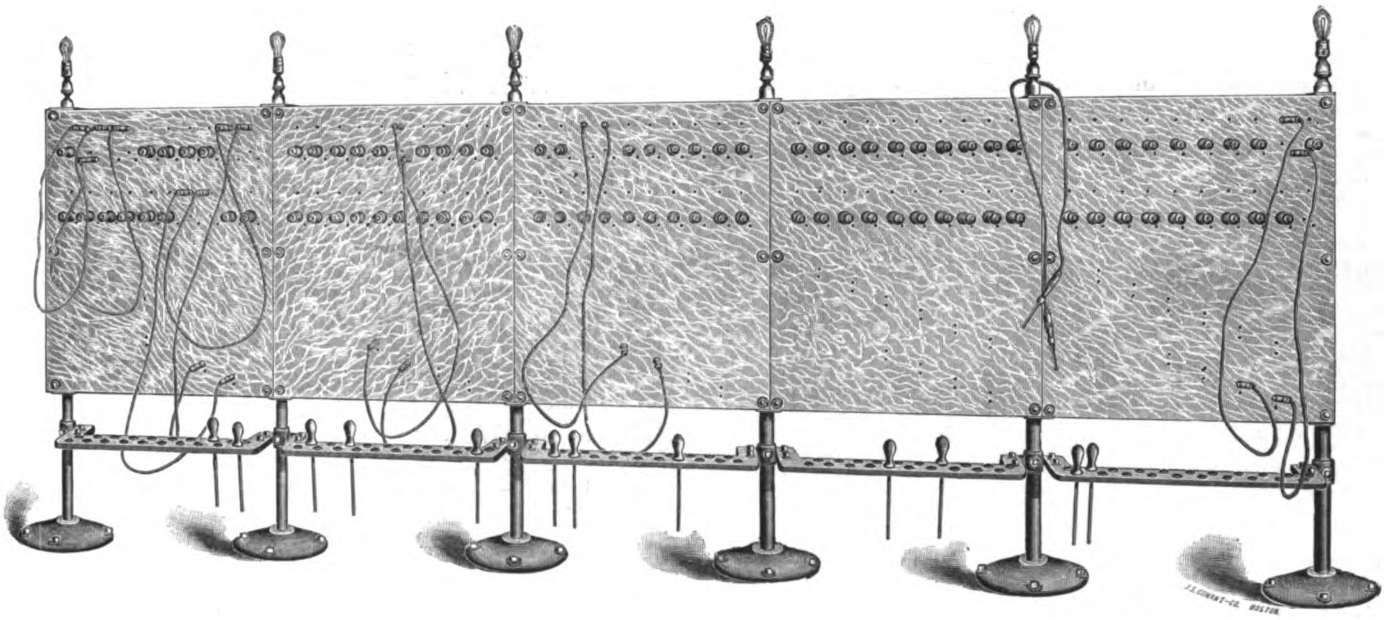
Any user of carbon brushes knows the extreme difficulty he has in getting a perfect bearing through the entire surface of the brush that is supposed to rest upon the commutator. It is almost impossible to get a brush to bear all over until it has worn itself into position by time. This preparation, if used in a proper manner when a new set of brushes is put on a machine, will at once build up the brush so that it will bear its entire surface on the commutator, as there is a preparation in this compound that assimilates readily with the carbon brush and becomes a part of it.

The E. G. Bernard Company, of Troy, N. Y., the manufacturers, state that they have used this preserver for some years on their own plants. and in putting it on the market and recommending it to owners of dynamos they guarantee an article of rare merit and very cheap in price

A Unique Switchboard.

Notwithstanding the stagnation and depression that have prevailed for so long a time throughout the electrical field, it is a fact and a pleasure to know that at least some firms have experienced little, if anything, of the pinching bad times, having been quite busy without intermission right along, and this because of the excellency of their work and the high reputation of their goods having brought them into increasing demand. This statement applies fully and unreservedly to the W. S. Hill Electric Company of Boston, Mass., which are rapidly coming to the front as manufacturers of high-grade switchboards and switches. During the general depression of the last few months the company have been pushed to their utmost capacity to fill orders, running nights a portion of the time, which speaks volumes for their reputation.

The accompanying cut shows a 50 Circuit Arc Switchboard that has been recently constructed for the Narragansett Electric Lighting Company of Providence, R. I., besides which they have completed several others, among them one, similar to the one illustrated, for the Lynn Gas and Electric Company of Lynn, Mass., for 24 circuits, and we understand they are now at work on an 8 panel alternating switchboard to take care of six 7,000 light machines and have several more under consideration.



Switchboard, Narragansett Lighting Station, Built by the W. S. Hill Electric Company.

One of the prominent features of the arc switchboard is that all working and contact parts are blind-fastened to the back side of the boards in the most rigid manner, avoiding the necessity of having belts go through the board, so that there is absolutely no metal on the face of it to appear unsightly or be dangerous to the operator.

This company's very large and complete line of switches is unexcelled, and their business in this direction has assumed rapidly-increasing proportions. They recently shipped on one order switches aggregating over three and one-half tons in weight, and comprising some of 1,000 and others of 4,000 amperes capacity, the latter being one of the largest, if not the largest, ever made in this country.

A large number of finished parts for switchboards and switches are kept constantly on hand, ready to assemble at a moment's notice, thus insuring prompt delivery.

The company is represented in New York by The Elson & Brewster Engineering Company, No. 122 Liberty street, who are selling quantities of high-grade goods, for which this firm is now quite famous.

Diamond Apparatus in Chicago.

Taylor, Goodhue & Ames have resigned the agency of the Wagner motors and transformers and are placing on the market a full line of motors, dynamos and transformers, manufactured by the Diamond Electric Manufacturing Company, and for which the firm of Taylor, Goodhue & Ames is sole selling agent.

The Diamond transformer has always been a favorite with central station men and the improvements made during the past twelve months place it well in the front rank and merit the consideration of all buyers of electrical apparatus.

The diamond motors and dynamos are of the latest type, combining slow speed with handsome appearance, high efficiency and good wearing qualities. They have long passed the experimental stage and are in successful operation to-day in various parts of the country.

Diamond machines of fifteen horse power and larger are of the four pole type, smaller sizes are two pole.

A Speed Indicator.

We illustrate herewith a novel and valuable instrument which shows at sight, continuously, the speed and variations of speed of any machine to which it may be connected. It may be placed at the machine in the office, in the cabin of the steam yacht, or wherever motion can be conveyed to it by a small cord or by friction. Connected to an engine, it plainly shows irregularities in the stroke due to a light balance wheel, improper setting of the valve, or other cause. Connected to a dynamo or other driven machine, it will show errors in belting or operating, and leads to the discovery and correction of irregularities and defects, thus avoiding loss in product, damaged products, damage to machinery or other loss in results, saving even in an hour, or a moment, many times the cost of the gauge.

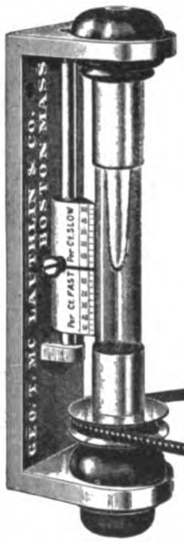
Mr. J. H. Henderson, engineer-in-chief General Electric Company, New York, says:

"I consider this gauge a most accurate and useful little instrument. It is based upon the well-known law that the surface of a liquid in rotation assumes the form of a parabola, being acted upon horizontally by centrifugal force and vertically by gravity.

"One of the instruments, suitably connected to an engine (or other machine), will show whether the speed is up to the mark at a glance, the index being set to correspond to the normal number of revolutions per minute.

"The gauge gives the best results when driven at a high speed, when a small variation will make quite a difference in the indication.

"Most tachometers have springs, levers and other mechanism—all of which are liable to get out of order, but this one has only the very simple parts necessary to bring it into action, and is based on two fundamental physical laws which cannot possibly change."



The McLauthlin Speed Indicator.

It is especially adapted for connection to engines, dynamos, looms, and all other machines wherever it is desirable to know at a glance whether normal speed is being maintained.

This gauge is patented and sold by Geo. T. McLauthlin & Company, 120 Fulton street, Boston, Mass.

Commercial Electric Engineering Company.

As noted in another column, articles of association of the Commercial Electric Engineering Company of Detroit have been filed, the authorized capital being $50,000, $16,250 of which has been paid in. The business of the company will be that of electrical engineering and construction and general electric supplies. The company has opened temporary offices at 47 and 51 Hodges Block, Detroit, and have already secured several contracts for central station lighting plants. The company will represent the Standard Electric Company's system of arc lighting in Michigan, Ohio and Indiana, and is under the management of G. E. Fisher, formerly with the Commercial Electric Company of Detroit.

COMMERCIAL PARAGRAPHS.

The F. E. Belden Mica Company, of Boston, which owns and operates some of the best mica mines in this country and does one of the largest businesses in that specialty, continues in the enjoyment of its wonted prosperity. It has just declared its regular monthly dividend, which is payable on November 2.

The Hawks Electric Company, of Boston, one of the most prosperous construction firms in New England, has something like a dozen large contracts in hand for lighting and power work. It has just closed a contract for the entire installation of 550 incandescent lamps in the streets of Attleboro, Mass.

The Campbell Electrical Supply Company, Boston, New England representative of the LaRoche Electric Company, Philadelphia, has secured a contract for an experimental plant to be installed in the laboratory of the Sheffield Scientific School, Yale College, New Haven, Conn. The LaRoche electric light system is becoming quite popular, contracts for several 1,000 light dynamos being in hand at the present time.

Mr. J. Bradford Sargent, Eastern representative of the Stirling Boiler Company, is receiving profuse congratulations from friends and customers on the honor won by the specialty he handles, the now well-known Stirling Safety Water Tube Boiler, at the World's Fair. The Blue Ribbon, Bronze Medal, together with a special Gold Medal—such were the honors—are distinctions and awards that any firm might be proud of, and as these were given in consideration of the superior excellence of the Stirling Boiler the manufacturers are entitled to congratulations.

"Anti-Thunderbolt" is the name given to a new insulating material for use on the armatures of dynamos, preventing burn-outs and short circuit, that is being used by several firms in and around Boston. It is really an insulating paper and comes highly recommended from the West, where it is being used with much satisfaction by electrical manufacturers, station superintendents and others. It is being placed on the market and pushed in a very successful manner by Mr. George Thomas, 205 and 207 South Canal Street, Chicago.

Some interesting tests have been made the last few days by the Massachusetts Electrical Engineering Company with a new brand of Paranite Fire-proof Wire. The tests were made to compare it with other brands of fire-proof wire, and the "Paranite" more than stood the tests applied, settling beyond all question that "Paranite" is a first-class fire-proof wire.

Throughout the protracted period of depression that has so long prevailed the wire manufacturers of New England have kept quite busy filling orders, and now the times are improving business is beginning to rush. Availing themselves of the promising outlook the Boston Electric Wire Company, whose factory is at Allston, Mass., has entered the field with very high grade magnet and annunciator wires and has already some good orders on hand. Their wires are manufactured on machines of an original and unique design, which, it is claimed, turn out their product much faster than any other machine, and with a finish of the very highest type, special attention being given to uniformity of covering. All wires from No. 40 to No. 16, single or double covered, are manufactured on these machines. Mr. C. A. Clark, one of the best known and most successful wire men in the country, has been appointed traveling sales agent.

The Metropolitan Electric Company of Chicago reports the receipt of a very important order for N. I. R. Wire. This wire is coming into favor very rapidly, contractors and builders finding that it meets every requirement. The Metropolitan carries a large stock of all sizes, and is enabled to fill orders promptly.

INCORPORATIONS.

The Hulings Electric Company, East Liverpool, Ohio—to manufacture electrical supplies, wire buildings, and engage in electric lighting, etc. Capital stock, $25,000. Promoters: Marcus H. Hulings, Alfred R. Walton, Sanford W. Durkee, T. W. Stevenson, W. P. Gardner.

Wanoosnoc Power Company, Fitchburg, Mass.—to furnish electric power for mechanical and manufacturing purposes. Capital stock, $20,000. Promoters: Daniel Simonds, Geo. M. Holman, A. T. Gifford.

The Pittsburg Electric Company, Pittsburg, Pa.—to supply light, heat and power by means of electricity. Capital stock, $5,000. Promoters: Jas. A. Curry, Wilkensburg, Pa.; Wm. H. Warwick, Bellevue, Pa.; Wm. M. Gillespie, Pittsburg, Pa.

The Manitou Electric Railway and Casino Company, Manitou, Col.—to construct, operate and maintain a system of electric street railways, etc. Capital stock, $125,000. Promoters: M. A. Leddy, Jno. Hurlbert, S. King, H. L. Cable, Manitou, Col.

The Canisteo Electric and Fuel Gas Company, Canisteo, N. Y.—to manufacture gas and electricity for use for public and private purposes in the village of Canisteo and town of Hornellsville. Capital stock, $50,000. Directors: William G. Porter, Levi S. Davis and William T. Bailey, of Canisteo; William H. Harris, of Washington, D. C.; John W. Trim, of Brooklyn, and John W. Farquhar, of Buffalo.

The Interstate Telephone Company of Kansas City, Kan. Capital stock, $100,000. Directors: Lyman Utter, Charles B. Riley, J. A. Trickett and M. G. McLean, of Kansas City, Kan., and L. C. Ferree, of Kansas City, Mo.

The Old Dominion Electrical Construction Company, Richmond, Va.—to manufacture all kinds of electrical machines, to furnish light and power, to equip and operate electric railways, and conduct any style of business requiring electrical devices. Capital stock, $25,000. The officers are: President, Maurice W. Thomas, Richmond; vice-president, J. Powell Eastwood, Portsmouth; secretary and treasurer, Maurice Hunter; directors, the above and W. B. Saunders and A. B. Guigon.

The Riverhead Electric Light Company—to furnish electricity for public and private purposes in the village of Riverhead, Suffolk County, N. Y. Capital stock, $7,500. Directors: John R. Perkins, J. Henry Perkins, T. M. Griffing, John H. Perkins, William H. Sweezey, George H. Skidmore and William M. Litchard, of Riverhead.

Simpson Electrical Supply Company, Chicage, Ill.—to manufacture and deal in electrical and other supplies. Capital stock, $12,000. Promoters: Geo. D. Coleman, Henry R. Pebbles, Thomas Fahey.

The Fullner-Danhoff Electric Company, Chicago, Ill.—to manufacture and deal in electric light batteries, appliances, etc. Capital stock, $5,000,000. Promoters: Franz Fullner, A. B. Coon, Henry A. Gates, Wm. B. Keep.

ELECTRICAL PATENT RECORD.

Letters Patent Issued October 17-25, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

507,247. Trolley-Wire Cleaner. Charles H. Thompson, Detroit, Mich., assignor of one-half to George A. Sheley, same place. Filed Dec. 19, 1892.

507,299. Trolley-Wire Insulator. Mowry S. Williams, Syracuse, N. Y., assignor of one-half to Stewart Worden, same place. Filed July 5, 1892.

507,339. Closed-Conduit Electric Railway. Robert Weir, Montclair, N. J. Filed May 10, 1893.

507,396. Electric Locomotive. James T. Wilson, Tyrone, Pa. Filed April 7, 1893.

507,498. Conduit for Electric Railways. George F. Green, Kalamazoo, Mich., assignor of one-half to Oliver S. Kelly; Martha L. Green, Springfield, Ohio, executrix of said George F. Green, deceased. Filed April 28, 1892.

507,539. Ice Scraper for Trolley Wires. William Heston, Alliance, Ohio. Filed Nov. 26, 1892.

507,606. Electric Railway Supply System. Granville T. Woods, New York, N. Y. Filed March 2, 1893.

507,641. Trolley Wheel Guard. John N. Akarman and Frederick Le Nois, Worcester, Mass. Filed April 10, 1893.

507,732. Switch for Trolley Wires. Gustavus A. Huben, Springfield, Ohio. Filed July 29, 1893.

507,733. Trolley for Electric Railways. Gustavus A. Huben, Springfield, Ohio. Filed July 29, 1893.

507,806. Conduit Railway Conductor. John W. Grantland, Philadelphia, Pa., assignor to Gilbert L. Parker, same place. Filed May 17, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

507,916. Electric Arc Lamp. William B. Luce, Brookline, Mass., assignor of one-third to E. S. Ritchie & Sons, same place. Filed Nov. 26, 1892.

507,313. Hanger Board for Electric Arc Lamps. James J. Wood, Fort Wayne, Ind. Filed June 7, 1893.

507,364. Hanger for Electric Lamps. Giles P. Hiler, Grand Haven, Mich. Filed Dec. 3, 1892.

507,554. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 31, 1893.

507,555. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 31, 1893.

507,556. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 31, 1893.

507,557. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed July 31, 1893.

507,558. Incandescent Electric Lamp. William E. Nickerson, Cambridge, Mass. Filed August 5, 1893.

507,600. Luminous Fountain. Paris E. Singer, London, England. Filed Dec. 28, 1892.

507,714. Electric Lamp Shade and Holder. Albert S. Marten, East Orange, N. J. Filed March 8, 1893.

507,867. Electric Arc Lamp. Henri Wilbrant, Brussels, Belgium, assignor to Henry Chapman and Louis Sterne, London, England. Filed July 6, 1893.

ELECTRIC BATTERIES.

507,139. Storage Battery. Charles W. Kennedy, Philadelphia, Pa. Filed Oct. 19, 1892.

507,463. Secondary Battery. Charles A. Smyth, Momence, Ill. Filed March 3, 1893.

507,708. Galvanic Battery. James A. S. Gregg, New Rochelle, N. Y. Filed April 3, 1890. Renewed Dec. 14, 1892.

DYNAMOS, MOTORS, ETC.

507,194. Armature for Dynamos. James J. Wood, Fort Wayne, Ind. Filed June 8, 1893.

507,297. Armature Coil for Dynamos. Gilbert Wilkes, Detroit, Mich., assignor to Hugh McMillan, same place. Filed June 20, 1893.

507,344. Commutator Brush Holder. James J. Wood, Fort Wayne, Ind. Filed June 27, 1893.

507,449. Reciprocating Electric Motor. Henri Pieper, Fils, Liege, Belgium. Filed Sept. 23, 1891.

507,547. Series Multiple Electric Controller. Arthur P. Knight, Boston, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Jan. 26, 1892.

507,629. System for Operating Electric Motors. Edmund C. Morgan, Chicago, Ill. Filed June 9, 1892.

507,658. Electric Motor. John F. Kelly and Cummings C. Chesney, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed Dec. 7, 1892.

507,690. Laminated Field Magnet Frame for Dynamo-Electric Machines. Andrew L. Riker, New York, N. Y. Filed July 27, 1893.

507,769. Motor. William J. Walker and Alexander L. Bedford, St. Louis, Mo. Filed March 15, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

507,424. Distributing Frame for Electric Wires. William S. Ford, Chelsea, and Bertram A. Lenfest, Wakefield, assignors to the American Bell Telephone Company, Boston, Mass. Filed March 31, 1892.

507,[illegible]65. Test and Signal Circuit and Appliance. Theodore Spencer, Cambridge, assignor to the American Bell Telephone Company, Boston, Mass. Filed Nov. 19, 1892.

507,568. Telephone Circuit. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Jan. 31, 1893.

507,694. Telephone Transmitter Circuit and Apparatus. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed May 22, 1893.

507,715. Telephone Transmitter. James H. Mason, Brooklyn, N. Y., assignor of nine-tenths to Alfred Van Derwerken, same place. Filed June 6, 1893.

507,728. Telephone. Stephen D. Field, Stockbridge, Mass. Filed June 30, 1893.

507,791. Machine Telegraphy. Patrick B. Delany, South Orange, N. J. Filed May 4, 1893.

ALARM AND SIGNALING APPARATUS.

507,125. Electric Signal for Railways. Albert B. Herrick, Bayonne, N. J., assignor to Arthur C. Fraser, trustee, Brooklyn, N. Y. Filed Feb 11, 1891.

507,170. Electric Alarm-Signal for Railway-Trains. James M. Rupel, Kansas City, Kans., assignor of two-thirds to Edward J. Haynes, same place, and Robert G. Rhodes, Kanses City, Mo. Filed April 26, 1892.

507,322. Electric Fire and Stable Alarm and Horse Releaser. Alexander R. Holmes, New York, N. Y. Filed Feb. 4, 1893.

507,510. Railway Time and Block Signal. Adelbert H. Thorp, Toledo, Ohio. Filed Feb. 7, 1893.

507,518. Electric Apparatus for Controlling Signals. Michael B. Leonard, Richmond, Va., assignor by mesne assignments, to the Electric Selector and Signal Company, of West Virginia. Filed March 14, 1892. Renewed March 25, 1893.

507,569. Electric-Protective System. Frederic G. Storey, Cambridge, Edward R. Andrews and John P. Cushing, Boston, and Howard F. Eaton, Quincy, Mass.; said Eaton and Cushing assignors to said Storey and Andrews. Filed June 24, 1893.

507,590. Automatic Bathometer and Shoal-Water Indicator. Nicolaus Potschinsky, Odessa, Russia. Filed Dec. 27, 1892.

507,869. Electric Signal Apparatus. John C. A. Xiezopolski and Charles Bode, Milwaukee, Wis. Filed June 29, 1893.

507,918 Electric Train and Switch Signal Device. George E. Miller, Saugus, Mass., assignor to the American Electric Train and Switch Signal Company, Portland, Me. Filed May 24, 1890.

507,925. Electric Burglar-Alarm. Thomas S. Patty, Cooper, Iowa. Filed Jan. 26, 1893.

507,959. Electric Alarm-Clock. Charles F. Wyman, Minneapolis, assignor to Lawrence E. Gerety and Henry W. Knapp, St. Paul, Minn. Filed Nov. 29, 1892.

ELECTRIC HEATERS.

507,217. Electric Heater. Charles L. Coombs, Washington, D. C., assignor of two-thirds to Edward Renaud and Allen B. Hayward, same place. Filed Feb. 11, 1893.

507,941. Electric Heater. William Snee, Pittsburg, Pa., assignor of thirteen-sixteenths to Abner Owens and John A. Snee, same place. Filed Dec. 27, 1892.

MISCELLANEOUS.

507,130. Electrolytic Production of Metals. Carl Hoepfner, Berlin, Germany. Filed July 16, 1888.

507,144. Apparatus for Controlling the Application of Electrical Currents. Robert Lundell, Brooklyn, assignor of two-thirds to Edward H. Johnson, New York, N. Y. Filed April 4, 1893.

507,150. Cut-Out. Louis W. Miller, Rochester, N. Y. Filed July 29, 1893.

507 205. Electric Selecting Device. Samuel S. Bogart, New York, N. Y., assignor by mesne assignments, to the Electric Selector and Signal Company of West Virginia. Filed Nov. 24, 1891.

507,206. Electric Selecting Device. Samuel S. Bogart, New York, N. Y., assignor, by mesne assignments to the Electric Selector and Signal Company, of West Virginia. Filed Dec. 9, 1891.

507,257. Insulated Wire. Herman H. Brown, Montreal, Canada. Filed Oct. 12, 1892.

507,269. Electric Door-Operating Apparatus. Oliver H. Hicks and Robertus F. Troy, Chicago, Ill.; said Troy assignor to said Hicks. Filed May 15, 1893.

507,298. Application of Electricity to Pianos or other keyed Instruments for Hygienic Purposes. William Willeringhaus, London, England. Filed May 29, 1893.

507,345. Resistance-Coil. James J. Wood, Fort Wayne, Ind. Filed June 30, 1893.

507,367. Electro-Thermal Bathing Apparatus. William F. Howe, Evanston, Wyo. Filed April 29, 1893.

507,374. Electrode. Farnham M. Lyte, London, England. Filed July 1, 1893.

507,391. System of Electrical Distribution. William Stanley, Jr., and John F. Kelly, Pittsfield, Mass. Filed March 8, 1892.

507,403. Connector. Charles Bell, Stroudsburg, Pa. Filed Jan. 28, 1893.

507,419. Electric Heating and Welding Apparatus. Chas. L. Coffin, Detroit, Mich. Filed Jan. 26, 1893.

507,458. Adjustable Induction-Coil. Edgar M. Senseney, St. Louis, Mo. Filed Dec. 5, 1892.

507,515. Electrical Ignitor for Gas or Hydrocarbon Engines. Paul A. N. Winand, Philadelphia, Pa. Filed March 10, 1892.

507,516. Electrical Ignitor for Gas or Hydrocarbon Engines. Paul A. N. Winand, Philadelphia, Pa. Filed March 14, 1892.

507,522. Electrical Steering-Gear. Charles W. Ayton, New York, N. Y. Filed July 13, 1892.

507,526. Electrical Transformer. William P. Carstarphen, Jr., Denver, Colo., assigner of two-thirds to James E. Gregg, same place, and Richard W. Webb, Santa Fe, N. Mex. Filed Nov. 7, 1892.

507,585. Automatic Time-Recorder. Isaac N. Lewis, Fort Wadsworth, N. Y. Filed Oct. 10, 1892.

507,589. Electric Car-Brake. Joseph H. McEvoy, Waterbury, Conn. Filed Dec. 30, 1892.

507,671. Electrically-Operated Machine for Molding Clay or Cement Pipes. Reinhold Boeklen, Omaha, Nebr., assignor to Jeff W. Bedford, same place. Filed July 30, 1891.

507,678. Insulating Compound. John J. Farnham, Chicago, Ill., assignor of one-half to John Bairstow, same place. Filed May 27, 1893.

507,689. Magnetic Frame for Field-Magnets. Andrew L. Riker, New York, N. Y. Filed July 27, 1893.

507,691. Electric-Circuit Testing and Switching Device. Miner Robinson, Newton, Mass. Filed March 6, 1893.

507,703. Electrically-Operated Piano. Lawrence J. Zimmerman, Linden, N. J., assignor to himself, and Geo. V. Hann, New York, N. Y. Filed Sept. 16, 1892.

507,768. Electric Coin-Controlled Fortune-Telling Machine. Adolph Waldman, St. Louis, Mo. Filed April 24, 1893.

507,785. Apparatus for Automatically Displaying Pictures. George Cook, London, England, and Charles K. Marr, Glasgow, Scotland. Filed March 20, 1893.

507,803. Combined Switch and Cut-Out for Electroliers. Iczak Goldkind, Max Stirn and Louis Stirn, New York, N. Y., assignors, by direct and mesne assignments, to Louis Stirn and Helen Somborm, same place. Filed April 25, 1893.

507,886. Electrolytic Apparatus. Thomas Craney, Bay City, Mich. Filed March 16, 1893.

507,912. Device for Demagnetizing Watches. Frank M. La Bolteaux, Cincinnati, Ohio, assignor of one-half to Henry Varwig, same place. Filed Jan. 21, 1893.

507,944. Apparatus for Lessening the Rolling of Vessels. John I. Thornycroft, London, England. Filed Nov. 26, 1889.

507,945. System of Electrical Transmission of Power. Charles J. Van Depoele, Lynn, Mass.; C. A. Coffin and Albert Wahl, administrators of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Oct. 23, 1890.

507,946. Portable Electric Pump. Charles J. Van Depoele, Lynn, Mass.; C. A. Coffin and Albert Wahl, administrators of said Van Depoele, deceased, assignors to the Thomson-Houston Electric Company, Boston, Mass. Filed Feb. 26, 1891.

To Inventors and Others.

United States and Foreign Patents Procured.

A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. NOVEMBER 22, 1893. CHICAGO. No. 19

THE S. S. WHITE DENTAL MANUFACTURING COMPANY'S WORLD'S FAIR EXHIBIT. (SEE PAGE 222.)

Electric Dental Appliances.

The S. S. White Dental Mfg. Co., who manufacture a large line of electrical goods for dental purposes, had an attractive exhibit in the gallery of Electricity Building, World's Fair, which is reproduced in our Frontispiece. The exhibit included a large line of Partz gravity batteries and all kinds of dental apparatus for use in connection with electricity. The dental motors and appliances were leading features of this exhibit. These motors, which are belted to dental engines, are regulated by rheostats and controlled by means of a treadle. Carpenter enamel rheostats are now being introduced for this purpose.

The motors are supplied with a magnetic clutch which is attached to the driving wheel, and is arranged to stop the machine instantly in case of accident. Some of these outfits are completely self-contained, and are ready for use by simply making connection with the current. These are usually wound for 100 volt circuits, but may be specially wound to run at any voltage or with batteries. This exhibit at first contained an outfit wound for a 500 volt street railway circuit, but as this voltage was not obtainable it was removed to the Liberal Arts Building for this general dental exhibit.

Among the smaller articles were cautery snares, electric mallets, miniature lamps, etc., the whole constituting a very complete display, which was awarded a medal and diploma.

The Practical Measurement of Alternating Currents.—II.

Coming next to the continuously recording watt hour meters, we reach that class which may be said to be the best adapted for general wants. One of the most efficient of these continuously recording watt hour meters is that invented by Prof. Elihu Thomson. This is a wattmeter in which the series coil carries the current, forming really the field magnet of a very small electromotor. The armature of this motor has a small commutator and brushes of the usual kind; and the armature, together with the added external resistances, constitutes the shunt circuit of the wattmeter. The shaft which carries the armature carries also a copper disc which is embraced by three horseshoe magnets. When the disc revolves eddy currents are set up in it which retard the motion. The number of revolutions of the disc in a given time is recorded by the counting mechanism attached to the shaft. Then since the force driving the armature round is at any instant proportional to the power passing through the instrument, and since the retarding force is proportional to the velocity, it follows that the number of revolutions in a given time represents the watt hours that have passed through the meter. In order to overcome the constant friction of the train of mechanism, there is a compound winding on the field magnet, consisting of a few turns of the shunt coil, which is arranged in such a direction that the driving force due to the fixed and movable shunt windings tends to overcome the permanent friction of the armature shaft. By properly treating the permanent magnets, it is found that they retain a constant field for long periods of time. The meter is so arranged that when working on a 100 volt circuit the shunt coil has a resistance of 1,000 ohms altogether, and takes therefore ·1 of an ampere. The loss in the meter, therefore, is only 10 watts, which is the power taken up in driving the motor. By properly arranging the shunt coil it is possible to make the same constant serve for a very long range of action, and one great advantage which this meter has is that it can be employed with both alternating and continuous currents. When properly adjusted this wattmeter is capable of very great accuracy in the measurement of alternating current energy.

The lecturer spoke of the Brillié meter as one of the same type as the Frager meter, that is to say, it is an intermittent recording wattmeter. The Mengarini recording meter, which has been extensively used in Rome, was also exhibited.

Reviewing the whole of these meters as used for alternating current measurement, the following rough classification was given :—

1. Graphic recording ammeters.
2. Graphic recording wattmeters.
3. Continuously recording ampere-hour meters.
4. Intermittent recording wattmeters.
5. Continuously recording wattmeters.

It might be asked at this stage what ought to be the characteristics and requirements in a good commercial meter for the measurement of electric energy supply to houses for lighting and other purposes. Most persons, without experience, would probably say that the first requirement in a meter is accuracy; but, as a practical matter, accuracy is not of so much importance as that the meter should never go far wrong. A type of meter which is capable of measuring, under some conditions, to ·1 of accuracy, and at other times is liable to make errors of 150 per cent. in actual practice, is not nearly so useful as a meter which will not read closer than 1 per cent., and yet which, in actual practice, proves never to go more than 3 per cent. wrong. The next condition with which a meter must comply is that it shall consume little power. Since a meter is connected to a circuit continually, if it absorbs power, the sum total of all these consumptions may amount to a serious item. It has been pointed out that in the case of voltmeters a continuous power absorption of 20 watts, during the whole year, amounts to an annual consumption of 160 units of electric energy, showing that small power consumption is certainly important in appraising a meter.

The third great requisite is, that the meter ought not to require elaborate care and delicacy in fixing; it should be hardy enough to be easy of carriage. House meters have to be fixed in places which are sometimes subject to vibration, dampness, etc., and a meter for such purposes ought, therefore, to be hardy enough to stand these conditions. The fourth condition is, that the meter must be so constructed in principle as not to be capable of being easily tampered with, or its indications made to vary even when enclosed in a lock-up case. To the above requirements ought, of course, to be added the broad and general conditions of structure and cheapness in price, as far as consistent with good workmanship.

In the distribution of alternating currents for commercial purposes, not only is it necessary to be able to measure the power or energy supplied to the consumer on the lamp circuits, but it is also required to be able to measure the power and energy sent out from the alternating current station which is supplying, generally, transformer circuits. Hence we have to consider the special difficulties of making such measurements on circuits which have a considerable self-induction, or in which the power factor of the circuits is below unity. During the past two years, Dr. Fleming had paid particular attention to this subject, in a long series of researches on the efficiency of transformers; and had thereby been led to study most of the various methods which, from time to time, have been proposed for measuring alternating current energy. Passing over impracticable suggestions, he proceeded to describe the methods which had proved, in his experience, satisfactory and workable. There are two instruments for this purpose which are capable of giving such results for the measurement of alternating current energy on inductive circuits—the Thomson recording wattmeter and the Mengarini wattmeter. Generally speaking, these measurements have to be taken on high-tension circuits; for instance, the very common case of an alternating current station, supplying alternating current at a pressure of 2,000 volts on transformer circuits. One method of employing either of the above wattmeters for the measurement of energy would be to place a non-inductive resistance of sufficient magnitude in series with a shunt coil, and to put the series coil in circuit with one of the primary mains. In such an arrangement there would be certain disadvantages. In the first place the Thomson recording wattmeter takes a current of about one-tenth of an ampere through the shunt, and hence we should have to add to the shunt coil, the resistance of which is about 1,000 ohms, another 19,000 ohms of non-inductive resistance, and then, when this was done, the power wasted in the whole of these shunt circuits would be 200 watts. If they were connected to the mains throughout the whole year, the waste of energy in these shunt circuits would be something like 1,600 Board of Trade units, and if we reckon the manufacturing cost of these at only 2d. a unit, the expense would be something like £12 per annum, merely to supply the shunt circuit with current. But this difficulty can be got over, and also the difficulty of constructing a large, non-inductive resistance of 20,000 ohms—sufficiently well divided up not to be in any danger of breaking with 2,000 volts pressure—by the adoption of a transformer to excite the shunt circuits in the way described in the last lecture. A small transformer is employed transforming down from 2,000 to 100 volts, and, as this transformer is only to supply one-tenth of an ampere on its secondary circuit, it can be made very small, not more than, say, a tenth of a horsepower in capacity. It can, therefore, be made to waste not more than about 10 to 20 watts in itself. This transformer has its primary circuits connected across the primary mains, and its secondary circuit is connected across the terminals of the shunt circuit of the Thomson wattmeter and so joined up that the current in the shunt circuit of the wattmeter is in the same direction and has the same magnitude as if the wattmeter were joined up simply on a 100-volt circuit in the ordinary way.

The wattmeter in itself only wastes about 10 watts in its shunt circuit, and therefore the whole arrangement of the transformer and wattmeter can be made to waste not more than, say, 25 to 30 watts instead of 200; the reduction in the cost of up-keep is reduced to something like 200 units a year instead of 1,600. The primary current going out of the station is then taken through the series coil of the Thomson wattmeter, and in order to keep all parts of the wattmeter at the same potential, one terminal of the secondary circuit of the little transformer is also joined up to the primary main on the side nearest to it. It is usual to mount the transformer and wattmeter on one board and then to insulate well the whole of this board. The first step is, now, to calibrate the wattmeter. This can be done most easily on a 100-volt circuit by passing through the meter known powers and observing the readings on the dial. In order to obtain what may be called "the high tension constant" of the wattmeter, the constant of the meter has then to be multiplied by the transformation ratio of the small transformer. When this is done the meter can be set up in the station in such a way that the whole current going out of the station passes through the meter, and the engineer can, by taking observations from day to day, record the whole number of units which have been taken out from the generating station on the primary circuits in any interval of time. In exactly the same way, Dr. Fleming has found that it is possible to employ a Mengarini wattmeter coupled with a transformer and placed on the primary circuit. This has the advantage that it not only enables us to record the whole of the energy going out of the station in a given time, but it tells us, at any instant, the primary watts.

Before placing confidence in either of these two methods, Dr. Fleming made a very careful series of experiments and observations on an inductive alternating primary circuit, in which was employed the Thomson self-integrating wattmeter, as above described, to measure the whole number of units sent out along that primary circuit in four hours, and at the same time observations were made on the same circuit by means of a wattmeter to obtain the power sent out at intervals of minutes. When these observations were reduced and compared it was found that the power sent out in four hours, as determined by the observations, was 66·924 units in the wattmeter, and the energy given by the self-integrating Thomson wattmeter in the same time was 66·946. It thus became evident that the Thomson recording wattmeter was capable of giving very accurate results as a primary wattmeter, and that there is no reason whatever why the record of the primary energy sent out should not be made in alternating current stations with the same accuracy as in the case of continuous current stations.

To complete arrangements it would be desirable in the case of an alternating current station, in order to enable the engineer to know exactly what the result of his working is, to act as follows: On the primary should be put, in the first instance, an ammeter capable of measuring alternating currents and giving the mean square value. In the second place, an electrostatic high tension voltmeter should be connected across the mains in order to give the high tension volts. In front of this instrument should be a Mengarini wattmeter and a Thomson self-recording wattmeter, the whole primary current from the station going through the series coils of these instruments. The shunt circuits of these instruments should be excited by a small transformer, transforming down from a working pressure to 100 or 50 volts. These instruments would then enable the engineer, by daily readings, to record, first, the energy sent out of the primary circuits in Board of Trade units in any time; secondly, the power being sent out at any instant, measured in watts; thirdly, the primary current being sent out at any instant, and the primary pressure; and from the product of these two, the apparent power being sent out at any instant; and, fourthly, from the readings of the real and apparent power, the power factor of the station could be ascertained at any instant.

By comparing these readings with the sum total of the house meters, taken at any intervals, the engineer would be enabled to know the efficiency of distribution of his alternating current station, and to reckon out not only the cost of the unit sold, but the cost of the unit generated, and to watch and know the effect of any alterations that are made in the transformer system. It is only by adopting such methods of measurement that engineers in charge of alternating current stations will be able to remove the reproach which is sometimes hurled at them, that they have no means of measuring the energy or power they are supplying, or of knowing how much of what they make is sold.

In concluding, Dr. Fleming thanked those who had lent him instruments to enable him to show the experiments. His endeavor had been to put the subject in as practical a manner as possible; the cream of practical experience rather than the milk of mere theory. The practical measurement of alternating currents might be more difficult in many respects than the measurements of continuous currents; but, at any rate, there was the satisfaction of knowing that it is now placed on a basis equally certain.

Recollections of Werner Von Siemens.[*]

I—Early Vicissitudes and Their Lessons.

In the autumn of 1840 I was transferred to Wittenberg, where I had to enjoy for a year the dubious pleasures of life in a small garrison town. All the more eagerly did I continue my scientific studies. In that year Jacobi's discovery was made known in Germany of precipitating copper in a metallic form by means of the galvanic current from a solution of the sulphate. This process interested me in a high degree, as it evidently was the key to a whole class of hitherto unknown phenomena. As I succeeded well with the copper precipitates I tried also to precipitate other metals in the same way, but only with moderate success owing to my limited means and apparatus.

My studies were interrupted by an event which in its consequences had an important influence on my future career. I was condemned (for acting as second in a duel) to confinement in the citadel of Magdeburg and had to report myself there on the confirmation of the sentence. The prospect of being shut up for at least half a year without occupation was not pleasant, but I consoled myself with the thought that I should have a good deal of leisure time for my studies. In order to make good use of this time I searched out a chemist's shop on my way to the citadel, and provided myself with the necessary means for pursuing my experiments in electrolysis. A friendly young fellow in the business promised not only to smuggle these articles into the citadel, but also to execute promptly future orders, and conscientiously kept his promise.

Accordingly I set up a small laboratory in my barred but roomy cell and was quite contented with my situation. Fortune favored me in my work. I remembered that some time ago I had tried experiments with my brother-in-law Himly in Göttingen for the production of pictures according to the process made known a little while before by Daguerre, and that hyposulphite of soda employed in these experiments had dissolved otherwise insoluble salts of gold and silver. I determined therefore to proceed on these lines, and to test the applicability of such solutions for electrolysis. To my unspeakable joy the experiment succeeded in a surprising manner. I believe it was one of the happiest moments of my life when a German silver teaspoon, which I had dipped into a beaker filled with a solution of hyposulphite of gold and connected with the zinc pole of a Daniell battery, whilst the copper pole was connected with a louis d'or as anode, changed in a few minutes into a golden spoon of the finest and purest lustre.

Galvanic gilding and plating was then, at least in Germany, still quite new and naturally caused a sensation in the circle of my comrades and acquaintances. I almost concluded a bargain with a Magdeburg jeweller, who had heard of the marvel and visited me in the citadel, whereby I sold him the right of making use of my process for forty louis d'or, which supplied me with the required means for making further experiments.

In the meantime a month of my confinement had elapsed, and I imagined I should have at least a few more months quietly to continue my work. I improved my apparatus and lodged a petition for a patent, whereupon with surprising rapidity a Prussian patent for five years was granted me. But the officer of the guard unexpectedly appeared and to my great terror, I must confess, handed me a royal order-in-council announcing my pardon.

Luckily I was not again sent to Wittenberg, but received an order to go to the pyrotechnic factory at Spandau. My discovery had in the eyes of my superiors doubtless made me appear less qualified for actual service! The firework factory was a relic of the old times when "gunnery" (Constablerthum) was still an art, of which the manufacture of fireworks was held to be the crown. My interest in the activity assigned to me was great; in good spirits I repaired to Spandau and took possession of the rooms in the citadel allotted to the pyrotechnic manufacture.

My new occupation was in fact very interesting, and I devoted myself to it with the greater eagerness as a large order had arrived at the pyrotechnic department for a quantity of fireworks, which it was intended to let off on the birthday of the Russian Empress in the Park of Prince Charles at Glienicke, near Potsdam. Owing to the progress of chemistry means were afforded at that time for the production of very beautiful colored flames unknown to the old gunners. My fireworks on the Havel Lake at Glienicke brought me therefore much honor and recognition, especially by the splendor of their colors. I was asked to the prince's table, and received an invitation to engage the young Prince Frederick Charles in a sailing match, as the sailing boat in which I had come from Spandau to Glienicke had distinguished itself by its excellent speed. I had the honor of conquering the future victor of famous battles, who even then impressed me in a high degree by his resolute, energetic character, or his "smartness," as one now expresses it.

With the letting off of these fireworks my command at the pyrotechnic factory came to an end, and to my delight I was ordered to Berlin for service in the ordnance department. Through this transference my greatest wish was fulfilled, to obtain time and opportunity for further scientific studies and for increasing my technical knowledge.

But there were also other reasons which made this change welcome to me. After my parents' death the duty devolved upon me of providing for my younger brothers and sisters, of whom my youngest brother Otto was at our mother's death only in his third year. The farming of the domains still remained, it is true, for a term of years in the hands of the family, but the times continued to be extremely bad for agriculture, so that the slight profits which were made by my brothers Hans and Ferdinand by farming did not suffice for the education of the children. I was therefore obliged to look out for some way of earning money in order to fulfil my obligations as senior of the family, and that appeared to me to be easier in Berlin than elsewhere.

My brother William had meanwhile completed his course at the Magdeburg School, and at my suggestion had gone for a year to Göttingen, in order to prosecute his scientific studies. After that he entered as pupil the Count Stolberg Engineering Works in Magdeburg. He there devoted himself with great energy to practical engineering, which just then was undergoing rapid development in Germany in consequence of the introduction of railways.

I kept up a frequent correspondence with William, and got him to communicate to me the problems which exercised the constructive faculty. One such problem was the precise regulation of steam engines which were assisted by wind or water mills. William's plan did not satisfy me, and I proposed to employ as regulative principle a heavy freely swinging circular pendulum, which, connected with the engine to be regulated by a differential mechanism, might effect an absolutely uniform rotation, instead of diminishing the irregularities by the only means then known, the very imperfect regulator of Watt. To this suggestion was due the construction of the differential governor, to which I shall return in the sequel.

---

[*] Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

In Berlin my efforts to earn money by my inventions were soon attended with success, although I was very much hampered by being as a military officer considerably restricted in the choice of devices for initiating business undertakings. I succeeded in concluding an agreement with the German silver manufacturer, J. Henniger, by which I agreed to set up an establishment for him for gilding and plating in accordance with my patent in return for a share in the profits. Thus arose the first establishment of the kind in Germany. In England, a Mr. Elkington had already started a similar establishment, employing another process, now in general use—viz., depositing from gold and silver cyanides—which soon obtained great success.

In the negotiations with regard to the Berlin plan and the fitting up of the establishment, I I was materially assisted by my brother William, who had paid me a holiday visit, and who succeeded at the same time in inducing a Berlin engineering firm to adopt the differential governor. As he clearly showed talent for such negotiations and himself wanted to get to know England, we agreed that he should try to utilize my inventions in that country, and for this purpose obtain a longer leave of absence from his factory. Considerable means I could certainly not afford him for his journey, and I have often wondered how in spite of this he attained his end. With excellent judgment he went straight to our competitor Elkington, who at first cut him short with the remark that we had no right to use our process in England, as his patent gave him the exclusive right to employ electric currents, produced by electric batteries or by induction, for depositing gold and silver. William had sufficient presence of mind to reply that he employed thermo-electric currents, therefore did not infringe his patent. I did in fact once succeed in making a thermo-electric battery, consisting of pairs of bars of iron and German silver, with which we could very well precipitate gold and silver from hyposulphite solutions. As a consequence William succeeded in selling our English patent to Elkington for £1,500. This in our then circumstances was a colossal sum.

I had meanwhile made two more discoveries which William was likewise to try to turn to account there. The prosecution of my experiments in electrolysis had led me to attempt to get also good deposits of nickel from a solution of the double salt of sulphate of nickel and sulphate of ammonia. This nickelizing appeared of especial importance for engraved copper plate, which, provided with a coating of nickel, allowed of a far larger number of impressions, without the fineness of the engraving being blunted by the nickelizing. To derive benefits from this process I had made a compact with a Berlin house, from which I expected considerable profits. Unluckily, however, soon afterwards the galvanic depositing of iron from the corresponding iron solution was discovered, which had the great advantage over the nickel coating that it could be easily renewed when worn out, in that the iron could be again liberated by dilute of sulphuric acid and the plate then coated afresh with iron. This made my nickelizing worthless for this purpose. A few years later it was again discovered and made known by Professor Böttger, but has only in recent times been much employed in industrial operations.

The second discovery consisted in the application of the zinc printing to a rotating fly-press, which process had just then come to be known. With the help of a skilful mechanician, the watchmaker Leonhardt, I had prepared a model of such a press, which very satisfactorily executed the necessary operations for producing lithographic impressions from a cylindrical zinc plate. But it subsequently turned out on its employment on the large scale by William in England that zinc printing allowed of no rapid repetition of impressions. After from 150 to 200 impressions the work had to be interrupted for a pretty long time, or else an obliteration of the reprint on the cylinder took place.

Returned to Berlin I very seriously reflected on the aims I had lately been pursuing, and saw clearly that the chase of discoveries, by which I had allowed myself to be carried away through the facility of a first success, would if continued probably be my own and my brother's ruin. I accordingly got rid of all my inventions, sold even my share in the manufactory set up in Berlin, and devoted myself again with heart and soul to serious scientific study. I attended courses at the Berlin University, soon, however, perceived to my dismay from the lectures of the celebrated mathematician Jacobi that my previous training was insufficient to enable me to follow him to the end. This imperfect schooling in scientific study has always to my great regret kept me back and crippled my efforts. All the more grateful am I to some of my earlier teachers, among whom I must specially mention the physicists Magnus, Dove and Riess, for friendly reception into their highly interesting circles. I also owe many thanks to the younger Berlin physicists, who allowed me to take part in founding the Physical Society. That was a wonderfully stimulating association of talented young scientists, who subsequently almost without exception became celebrated by their achievements. I need mention only the names of Du Bois-Reymond, Brücke, Helmholtz, Clausius, Wiedemann, Ludwig, Beetz and Knoblauch. Intercourse and co-operation with these young men, distinguished by talent and earnest endeavor, strengthened my preference for scientific study and labors, and kindled in me the determination to be in future the votary of strict science alone.

But circumstances were stronger than my will, and the native impulse never to let acquired knowledge lie idle, but as far as possible to make some use of it, led me ever and again back to technology. And so it has been my life long. My affection has always been given to pure science as such, but my labors and achievements have been for the most part in the domain of applied science.

This technical turn was especially favored and supported by the Polytechnic Society, to which as a young officer I zealously devoted myself. I took an active part in the proceedings, and in the answering of the questions which were deposited in the query box. The answering and discussing of these soon formed a part of my regular activity and proved a good school for me. My scientific study stood me in good stead, and it became clear to me that technical progress is only to be attained by the diffusion of scientific knowledge among technologists.

At that time there still existed an unbridged gulf between pure and applied science. The meritorious Beuth, who is unquestionably to be regarded as the founder of the technical science of North Germany, had indeed in the Berlin Industrial Institute erected an institution which was especially designed for the diffusion of scientific knowledge among young technologists. The existence of this institute, out of which arose the Industrial Academy and finally the Technical College in Charlottenburg, was however too short for raising the level of education of the craftsmen of the period.

Through my activity in the Polytechnic Society I arrived at the conviction that scientific knowledge and scientific methods of investigation are capable of developing technology to a degree far beyond anything that can be foreseen. It further had the advantage of making me personally acquainted with Berlin manufacturers, and of affording me personally an insight into the achievements and defects of the industry of the time. My advice was often sought by manufacturers, and I thereby became acquainted with the contrivances employed and the modes of working. It became clear to me that the industrial arts cannot advance by sudden leaps, as has often been possible to science through the fruitful ideas of a few remarkable men. A technical invention only obtains value and importance if technology itself has so far progressed that the invention is a practical one and supplies a need. Hence one so often sees the most considerable inventions unutilized for decennia, until all at once their great importance is recognized, their hour having arrived.

Of the scientific technical questions which at that time especially occupied me, and at the same time gave occasion to my first literary labors, the first owed its origin to a communication in a letter of my brother William with respect to an interesting engine which he had seen at work in Dundee. From a rather brief account it appeared that this engine was not driven by steam but by heated air. This idea interested me exceedingly, since it appeared to afford a foundation for an advantageous transformation of the whole engine construction art. In a paper entitled "On the Use of Heated Air as Mechanical Power," contributed in 1845 to *Dingler's Polytechnic Journal*, I described the theory of such air engines, and gave also a sketch of the construction of such a one as I conceived to be practicable.

My theory was based entirely on the principle of the conservation of energy, which had been advanced by Mayer and mathematically worked out by Helmholtz in his celebrated memoir "On the Conservation of Energy," originally read before the Physical Society. Later on my brothers William and Frederick occupied themselves a good deal with these engines, and constructed them in various forms. They too, however, unfortunately had to undergo the common experience of finding that engineering had by no means advanced far enough to allow of the discovery being utilized with advantage. Only small engines could be constructed on the basis of the above principle so as to work well for a length of time; for large ones the right material for the heating apparatus was and is still wanting.

In the same year I printed in *Dingler's Journal* a description of the already mentioned differential governor, to which in collaboration with my brother William I had tried to give the most varied forms.

Another question, which had already occupied me for a long time, was that of an exact measurement of the velocity of projectiles. The watchmaker Leonhardt, known as a skilled mechanician, and in the employ of the Artillery Commission, had constructed a clock which turned an indicator with great velocity when the latter was electro-magnetically connected with the clockwork.

The coupling and uncoupling of the indicator by the flying shot was attended however with great difficulties, which in spite of our efforts could not be quite overcome.

This led me to the idea of the employment of the electric spark for the measurement of velocity. In a paper, published in *Poggendorff's Annalen*, "On the Application of the Electric

Spark to the Measurement of Velocity," I demonstrated the possibility of accurately measuring the velocity of projectiles at every stage of their progress by means of a rapidly rotating polished steel cylinder, on which incident electric sparks could leave a distinct mark. This paper also contained the plan, only many years subsequently executed by me, of ascertaining by the same method the velocity of electricity itself in its conductors.

My interest in electrical experiments was most vividly stimulated by participating in the labors of Leonhardt, who was at the same time occupied with experiments, which the military staff had caused to be instituted, with regard to the substitution of electric for optic telegraphy. In the house of Hofrath Soltmann, father of an intimate comrade of mine, I had the opportunity of seeing the model of a Wheatstone indicator telegraph, and had taken part in the attempts to bring it into operation between the dwelling house and the establishment for artificial mineral waters at the end of a large garden. This, however, never succeeded, and I soon perceived the cause of these failures. It was traceable to the principle on which the apparatus was constructed, which required the turning of a handle with such regularity that the impulses of current produced had always sufficient strength to keep the clockwork of the receiving apparatus in motion. This was not attainable with certainty even if the apparatus worked in the room, and was altogether impossible where an important part of the current was lost through the imperfect insulation of the conductors.

Leonhardt, trying at the instance of the commission to remedy this defect, caused the impulses to be produced by clockwork, i. e., in quite regular intervals, which was certainly an improvement, but still did not suffice with the varying loss of current. This made it apparent to me that the problem was most completely to be solved by converting the indicator telegraphs into self-acting machines, each of which would automatically break and make the circuit. If two or more of such electrical machines were connected to *a single* electrical circuit a fresh impulse could only be given when *all* the inserted apparatus had completed their stroke, and this had again closed the circuit. This proved in the sequel a very fruitful principle for innumerable electro-technical applications. All the self-acting alarms or bells employed at the present time are based on the automatic interruption after a completed stroke first introduced as above stated.

The construction of these self-interrupting dial telegraphs I entrusted to a young mechanician, named Halske, with whom I had become acquainted through the Physical Society, and who at that time managed a small mechanical workshop, the business firm being known as Böttcher & Halske. As Halske at first entertained doubts whether my apparatus would act, I myself set up a couple of automatic telegraphs, composed of cigar boxes, tin plate, a few pieces of iron, and some insulated copper wires, which worked with perfect certainty. This unexpected result filled Halske with so much enthusiasm for a design capable of execution notwithstanding such defective materials that he gave himself up with the greatest eagerness to the construction of the first apparatus, and even declared himself ready to withdraw from his firm and in conjunction with me to devote himself entirely to telegraphy.

(*To be continued.*)

Milwaukee, Wis.—The Electric Light Company of South Milwaukee intends to enlarge its plant to accommodate a number of new factories that wish to put in electric lights.

SOCIETY NEWS.

American Institute of Electrical Engineers.

REPORT OF COMMITTEE ON LOCAL MEETINGS.

At the regular monthly meeting of Council, Wednesday evening, November 15, the committee appointed at the meeting on October 18 to consider the subject of Local Meetings reported as follows:

It is the opinion of the committee, first, that provision should be made for local meetings of the members at points inconveniently distant from New York for the reading and discussion of papers accepted by the Institute. Second, that the provision in Section VI of the Rules of the Institute, authorizing the secretary to "call a special meeting on a requisition signed by fifteen or more members," was not intended to and does not cover local meetings of the character contemplated in this report.

The following plan for the holding of local meetings of members was presented by the committee:

When not less than twenty members in any stated locality shall in writing notify the secretary of the Institute of their desire to hold local meetings, such request shall be presented to the council at its first meeting thereafter. The council shall then, upon the recommendation and nomination of the signers of the request for local meetings, appoint a local honorary secretary, who shall be a member or associate member of the Institute residing in the specified locality.

The duties of a local honorary secretary shall be in general to serve as a channel of communication between local members and the general body of members through the secretary and council. But no member in any locality shall be debarred from direct communication with the Institute.

In any locality where a local honorary secretary shall have been appointed, local meetings may be held, the local members to elect their own chairman, such meetings to be known as Meeting of the Members of the American Institute of Electrical Engineers, and such meetings shall be for the purpose of reading, by the authors or by proxy, and of discussing, papers accepted by the Institute and such papers only. Such local meetings shall be held simultaneously with the Institute meetings or subsequently; that is to say, no paper before the Institute shall be read or discussed at a local meeting in advance of its reading at the Institute meeting.

Wherever local meetings shall have been provided for, as in the foregoing section, the local honorary secretary shall be supplied by the secretary of the Institute with a suitable number of advance copies of papers to be read before the Institute, which copies he may distribute to the local members at their local meetings. The local honorary secretary shall transmit to the secretary of the Institute a report of the discussions at each local meeting, together with any written discussions or comments on papers that he may receive from members in his locality. Any member or associate may introduce a stranger to any meeting, but the latter shall not take part in the proceedings without the consent of the meeting.

The local honorary secretary shall transmit to the secretary of the Institute all papers offered by local members, but any member may send papers directly to the secretary of the Institute.

The publication of the discussions at local meetings in the Transactions of the Institute shall be subject to the same regulations and restrictions as govern the publication of discussions at the regular meetings of the Institute. No publication of papers or discussions at local meetings in local or other journals or newspapers is to be permitted without the sanction of the council or the secretary of the Institute.

The expense of local meetings shall be borne by the local members, and not become a charge upon the funds of the Institute.

The title, name and address of each local honorary secretary shall be printed in the publications of the Institute.

In dealing with the subject before it, and in preparing its report, your committee has carefully considered the documents and correspondence placed in its hands, particularly the paper of the secretary on "Monthly Meetings" and the plan for the establishment of chapters of the Institute drawn up by Dr. Emery, both of which were read at the October meeting.

The scheme for local meetings suggested in this report has been designed with the purpose of affording to members distant from the headquarters of the Institute opportunity to participate in its work on substantially the same footing as members whose location permits them to attend meetings held in New York. The Institute is a national body, having members in every section of the country, but with a large preponderance of membership relatively near headquarters. Its work and its publications have a national significance. Its subdivision into sections or chapters would detract from the unity and strength of its effort to serve the best interests of electrical science and industry.

The committee is of opinion that it would not be for the welfare of the Institute to create any separate local organizations or any class or classes of members not now provided for in its rules.

It is believed that the plan for local honorary secretaryships and for local meetings herewith submitted would meet fully the desire of members in diverse parts of the country to participate in the work of the Institute, and that it would avoid the disadvantage and disintegrating tendency that might arise from the formal establishment of a number of separate and distinct sub-societies.

Herbert Laws Webb, Chairman; A. E. Kennelly, M. I. Pupin, Wm. J. Hammer, Geo. M. Phelps, *Committee.*

The report was adopted by the Institute with some slight amendments.

The following associate members were transferred to full membership: Bion J. Arnold, Chicago, Ill.; Chas. D. Parkhurst, U. S. A., Fort McHenry, Md.; Alfred A. Dion, Ottawa, Ont.; Chas. F. Uebelacker, Cleveland, O.; Robert McA. Lloyd, New York.

The Ferris Wheel an Infringement.

Strange Interpretation of Patent Law.

William Somers, of Atlantic City, patentee of the roundabout wheels which are so common at Eastern resorts, has secured a verdict against the Ferris Wheel Company of Chicago for an infringement of his patent.

The case was tried in the Circuit Court at Chicago and afterward carried to the United States Court in Philadelphia, where evidence was taken two week ago.

Mr. Ferris on the witness stand testified that in 1892 he was in Atlantic City and rode on the Somers wheel. He considered it a popular amusement, and afterwards built from this suggestion the big Ferris wheel. The Court has not yet fixed the amount of damages on royalty.

Schuyler Electric Company's Affairs.

President C. E. Dustin of the Schuyler Electric Company is quoted in a recent interview as follows:

"The Schuyler Electric Company is an entirely separate corporation from the General Electric Company, that company simply being one of the stockholders. We are running few men at present, owing to the dull times, but expect to start up as soon as there is sufficient work to warrant it. We are making no shipments of machinery, nor of any materials, excepting such as has been made up and now being shipped on order. In closing down our factory we had orders which would keep us going probably for three or four months, but the payments on these would be long deferred, and I considered it the best of judgment to sail close to the wind and not be burdened with additional stock of goods with no prospective customer, or with no assurance of early payments. The result of this policy has been proved to be the very best, as the Schuyler Company was never in such good condition financially or in better shape for holding up until times improve."

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - Editor.
R. H. WILLOUGHBY, - - Associate Editor.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:

BOSTON:
W S. KEY, - Room 75, 120 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

United States, - - - - -	$2.50
In Clubs of Five or More, - - -	$2.00
Foreign Countries, - - - - - -	$4.50
Single Copies, - - - - -	$ .10

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

Entered at the N. Y. Post Office as Mail Matter of the Second-Class.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

The Lamp Situation.

The expiration of the Edison lamp patent in Great Britain has created renewed interest in the lamp situation on this side the water, and desultory discussion of the status of the Edison patent here has resulted. No new facts have been brought out, however; there has been at least no public announcement that the matter is to be brought before the courts for settlement.

There can be no question as to the expiration of the American patent next year; there is an open question as to whether or not it has actually expired now, but in matters of this nature editorial opinions count for little. A judicial opinion is what is needed, and inasmuch as the case could be brought to issue and decided at a trifling expense, there seems no good reason why outside lamp makers should not combine for this object.

We understand that at least one of the companies has in view the securing of a decision on its own account, and results may be looked for early next year.

The recent suit brought by the General Electric Company against the Davis Company at Springfield, who were engaged in refilling lamps only, shows that the owners of the patent are still prepared to fight.

We note in the English papers that nearly a dozen companies are already in the field there, and that the price of lamps has been reduced.

……o……

The Ansonia Company's Affairs.

The proposition for settlement offered by the Ansonia Electric Company, of Chicago and Ansonia, some weeks ago has created considerable comment. Although it was not printed in full in these columns, we assume that to those interested the terms are thoroughly known

We are informed that some of the largest creditors have refused to sign, and on the other hand, Mr. John B. Wallace, the president of the company, states positively his belief that all will sign and that the proposed arrangement will be a success.

We are convinced that the proposition as made was a serious mistake, and that the best interests of the trade would not be conserved by the continuance of the company on that basis.

We regret exceedingly that we feel called upon to make this statement, but the questions involved are serious ones and far-reaching in their possible consequences.

It is a disagreeable fact, but it is a fact, that electrical enterprises, from the point of view of credits in the financial world, are looked upon with suspicion, suspicion which is not wholly groundless, but which can easily be removed provided the leading houses in the trade conduct their affairs according to old-fashioned standards of honesty and business morality. The proposition of the Ansonia Company is not calculated to work an improvement in this direction. Its acceptance is putting a premium upon the disregard of honest obligations, and the continuance of the company on this basis must have a pernicious influence on smaller concerns when they find themselves losing money.

The greatest injustice, perhaps, would be done to the competitors of the company, some of whom, notwithstanding the falling off in business and other unfavorable features of the past three or four months, are courageously and honorably endeavoring to pay dollar for dollar.

The company might better make an entire surrender and begin anew. Their own chances of future success would be immeasurably brighter; and the creditors, at least those with whom we have talked, would prefer to realize 35 to 40 cents cash at once than take the chances of getting the full 60 cents on the dollar by the proposed plan.

We suspect that the high personal regard in which Mr. F. S. Terry is universally held has been a potent factor in moving many of the creditors to sign. We do not believe that personal considerations should influence men in a matter of such importance. And moreover, we believe that true friendship for Mr. Terry does not dictate any such policy on the part of the creditors.

He could put a new company on its feet in short order, but not even his prestige could make a success of the Ansonia Company after its flagrant violations of business obligations.

……o……

The General Electric Wreck.

The temporary activity of General Electric stock for one day last week aroused some interest in the present condition of the company. The speculators had many theories, but, as usual, their views were superficial, and they failed to reasonably explain a slump of 4 points in one day. As a matter of fact no explanation was necessary. The stock has no support, and can be moved downward at any time by a little pool such as caused the flutter referred to.

The interest of the trade is not so much in the stock market as in the actual business of the company, and the speculators and stockholders who are waiting for a rise to unload might with profit investigate the matter from the standpoint of the trade.

A director of the company who is known to Electricity said last week:

"General Electric affairs have been put in such shape that the company is no longer losing any money. It may not be making much, but it is not losing anything. It has no floating debt. The company has closed all of its works which are not absolutely necessary to the profitable operation of the plant. The company has never had as excellent management as it is having to-day."

This is a noteworthy statement. It is a frank admission that the company was at one time losing money. We all knew this much. But what becomes of Mr. Coffin's daily assertions for a year and a half that large profits were being earned? Moreover, the company has a debt and a big one. It may not be a "floating debt" Indeed many merchandise creditors whose bills are several months behind begin to believe it is a stationary debt. And as for management, there is no such thing.

In order to inform our readers as to the correct situation, a representative of this paper last week made a tour of the company's plants in the East. To know the condition of the company this was the place to begin.

What are the factories doing in comparison with other years?

At the Harrison lamp works a fair business is being done, though the factory is by no means working up to its full capacity. The shrinkage here is only noteworthy as emphasizing the fact that the lamp monopoly is thoroughly broken.

Our poetical contributors had already given us an inkling of the dry rot which has attacked the splendid plants at Lynn and Schenectady, but we were not prepared for the report made by our representative.

At Schenectady about 600 men are at work on half time. Many departments are closed, and the draughting room is deserted. Further discharges of men are looked for. The Schenectady works at one time gave employment to 4,000 people.

At Lynn the actual situation is worse than at Schenectady, though more men are employed. The factories are in a state of disorder, machinery is uncared for, dust is thick on everything, and there is no evidence of care or thought for the future. Here 1,500 men are at work on half time, as against 3,500 on full time a year and a half ago. In the draughting room there are about a dozen, as against 175.

All work at the Schuyler and Brush factories is practically suspended, not over a score of men being employed at last accounts in both places.

The results of the investigation at Lynn and Schenectady are worth further consideration. They have 2,100 men at work on half time, equivalent to 1,050 *men working at full time*, as against a high water mark of 7,500 *men at full time.*

We have already given the total business of the company last year as about $14,000,000. Using the number of men at work as a basis of estimate, the General Electric Company is now doing at the rate of $2,000,000 business for the year. This is not an encouraging showing. Little wonder that the directors have decided that it will be the part of wisdom to pass the dividend on the preferred stock which is due in January next.

Refuge cannot be taken in the generally depressed condition of business. There is not an electrical manufacturing concern in the country, if ever prosperous, that shows one-half the falling off.

The facts cannot be dodged. The asinine policy of the company has resulted in wreck and ruin to a once magnificent business.

There is moreover no possibility of an improvement in present conditions without a thorough and radical reorganization—a new and liberal policy, carried out by honest and capable men.

……o……

AN impressive lesson has been taught by the developments of the past summer, and this is that concerns should use more caution in their credits. Many good houses have been seriously crippled as a result of unwise conduct of this department of their business.

THERE is nothing encouraging in the latest reports from Eau Claire in regard to the affairs of the National Electric Company. The sale of the plant for $7,500 has not been confirmed, owing to the very natural objections filed by the Standard Electric Company and other Chicago creditors.

……o……

NOTHING would go further to place the electrical manufacturing and supply business upon a solid footing than the adoption by American companies of the plan of making full reports at least once a year, which might be published in the trade papers. This has been done with profit in England from the very inception of the business. Thus it might readily be known who are and who are not worthy of long and large credits.

……o……

WHILE contemplating with infinite satisfaction the merits of the American patent system, as described by a valued contributor to ELECTRICITY, we learned that the Ferris wheel had been declared an infringement in a suit brought by the man who first patented the nasty little wheels which are so common at Coney Island and elsewhere. Our own confidence in the American patent system is abiding, but thus it receives an occasional shock. How the idea of a wheel of this nature could be patented is a mystery, and how the Ferris wheel could be considered an infringement is a greater mystery. Its only point of similarity to the Atlantic City and Coney Island wheels is that it goes round. But all wheels go round, and we suspect that sometimes the head of a United States Circuit Judge goes round.

……o……

OUR office cat has given birth to four healthy kittens; they are now in training. We shall soon, therefore, be able to offer three to some of our contemporaries besides adding one to our own staff. We thought once of offering them to the *Electrical World*, as we know our neighbor needs them badly, but have decided not to do so; we think too much of our cats. It is supposed that the *World's* office cat committed suicide when confronted with the report of that lawsuit.

Business is Booming.

At Least That is What Mr. McDonald Told a Detroit Reporter.

Mr. R. T. McDonald, general manager and treasurer of the Fort Wayne Electric Light Company, and president of the Peninsular Company, was at the Cadillac yesterday. To a *Free Press* representative he said that the electric light business throughout the country was on the boom.

The innocent freshness of this recalls an incident connected with a campaign in Canada a few years ago when the Liberals were causing plenty of trouble for Sir John McDonald, and making capital of the alleged decadence morally and intellectually of the British nobility. Lord Dufferin had made an address before the Greek class of McGill University, and the reporter had given it out that "his lordship spoke to the class in the purest ancient Greek, without mispronouncing a word or making the slightest grammatical solecism." A friend of Sir John's came in smiling with this statement and asked, "How do you suppose the reporter knew that his lordship's Greek was correct?" "I told him," answered Sir John. "You told him? What do you know about Greek?" "Nothing, nothing at all; but I know a little about politics."

General Electric Rumors.

The Mysterious Company Excites Comment.

On Wednesday of last week there was a sharp downward movement in General Electric shares, the price going in an hour from 41½ to 38. The trading reached over 30,000 shares, being one-sixth of the total business on the Exchange for the day.

This started a fresh flood of gossip, and there was a rumor to suit every man's theory. The following are given as examples, taken from the various financial articles in the daily press:

"No payments of dividends on the stock are expected for a long time, but the company's officers assert that they hold the funds required for the December interest, amounting to about $250,000. One explanation of the weakness of the stock was that it was due to a recent adverse legal decision. It was also suspected that progress might have been made in the organization of the opposition company which has been threatened for some time."

"The sellers explained the selling as due to a scurry to get away from a bad investment. A receivership was hinted at, and it was explained that the company for want of ready capital had been compelled recently to forego bidding for very profitable contracts. Then it was said that there was to be a consolidation with the Westinghouse Company; but the Electric's officials denied this, and George Westinghouse declared that he would not accept General Electric as a gift."

"It was announced in the Board of Directors that C. H. Coster, of Drexel, Morgan & Company, and H. McK. Twombly would resign from the directory of the company, and that the syndicate that had undertaken to right the indebtedness of General Electric, receiving in return an option upon the treasury assets, would fail to qualify."

"The demonstration was made on the inside information that the Fort Wayne Company, which is one of the subsidiary companies of the General Electric, was on the point of going into the hands of a receiver, and the preliminary papers had already been drawn."

(*From the Boston News Bureau.*)

"The rumor having the most influence was that there had recently been an expert examination of the books of the company in the interest of certain holders of the securities and some unfavorable facts are alleged to have been developed.

"We are told that a foreign interest lately made an inquiry into the affairs of the company, and decided that it was best to close out its holdings of the stock.

"There is also a rumor of a consolidation with the Westinghouse on unfavorable terms.

"There is some talk of moving the accounting offices to New York.

"General Electric officers say that they are satisfied that the General Electric Company could liquidate and aside from franchises and good will return stockholders above $50 per share.

"A bid of $1,000 was made in Stock Exchange this morning for the right to exchange any time within a year 1,000 shares General Electric for 1,000 shares Westinghouse common."

A Common Sense View.

(*From the Daily America.*)

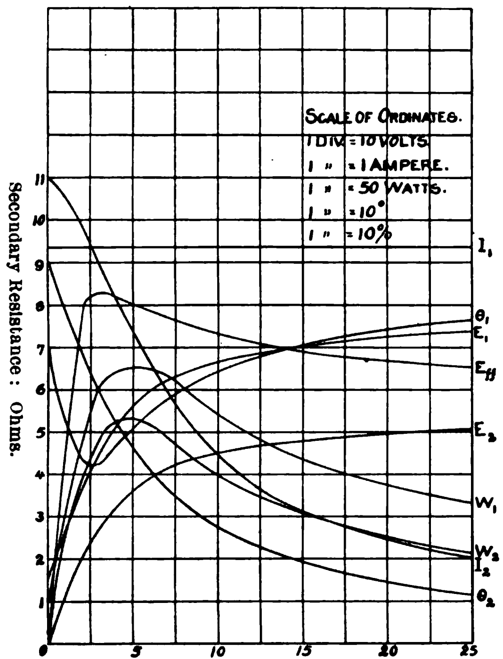
It has been repeatedly stated in this column that the assets of the General Electric Company and the restricted business it is now doing do not justify the price at which the stock has been selling ever since the panic. Now that it has gone down the toboggan slide 10 or 12 points to 39, the statement is still true. The fact of the matter is that the profits of the company at present are not sufficient to pay any dividends on the common stock, and there is no prospect in the near future that any such dividends can be paid. Without going too elaborately into calculations, it may be stated confidently that the stock is worth about 25 on the basis of its present revenues, and that is where it will land just as soon as the necessity for reorganization is announced, and I do not see how that can be very much longer delayed.

Transformer Diagrams Experimentally Determined.—III.*

BY DR. FREDERICK BEDELL,

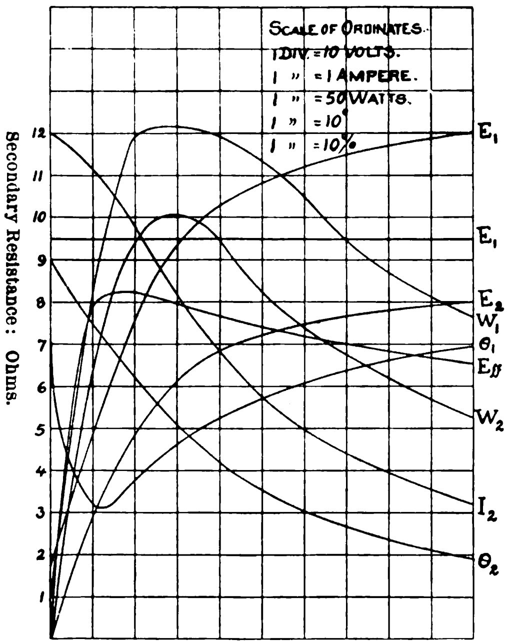
Assisted by A. W. Berresford, W. M. Craft and B. Gherardi, Jr.†

Rectangular Diagrams.—Rectangular diagrams do not indicate the direction of the quantities represented, but they show quantities in such a way that they are often superior to polar diagrams for indicating relative magnitude. For this purpose rectangular diagrams were drawn from the polar diagram Figs. 5-10, and two of these are shown in Figs. 13 and 14, for the tongue all out and all in respectively. These figures give the currents, electromotive forces, angles of lag, the power for the primary and for the secondary, and the efficiency of the transformer for different values of the secondary resistance. The curves explain themselves. It is interesting to note that the primary angle of lag on short circuit has about the same value, 70°, for all positions of the tongue. As the secondary resistance is increased, the angle decreases at first and then increases again. A study of Fig. 11 will show that this is explained by the shifting of the primary electromotive force semi-circle in Fig. 11, to the left, due to magnetic leakage. If the leakage were diminished, the primary semi circle would be moved toward the primary current $\overline{OA}$. In the rectangular diagrams, a diminishing of the magnetic leakage would cause the minimum point in the curve for θ_1 to shrink and disappear in the case of no leakage.



CONSTANT CURRENT. STEP DOWN. ARM AT 0°

FIG. 13.



CONSTANT CURRENT. STEP DOWN. ARM AT 180°

FIG. 14.

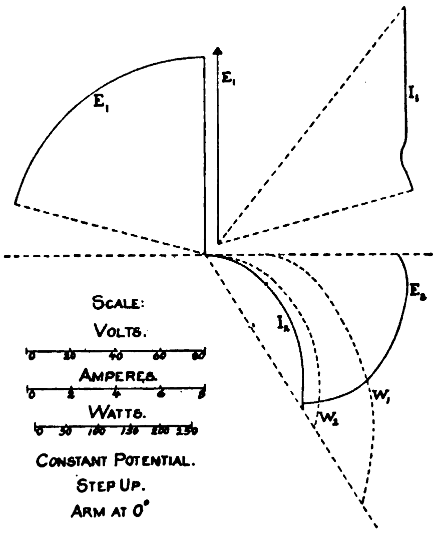


FIG. 15.

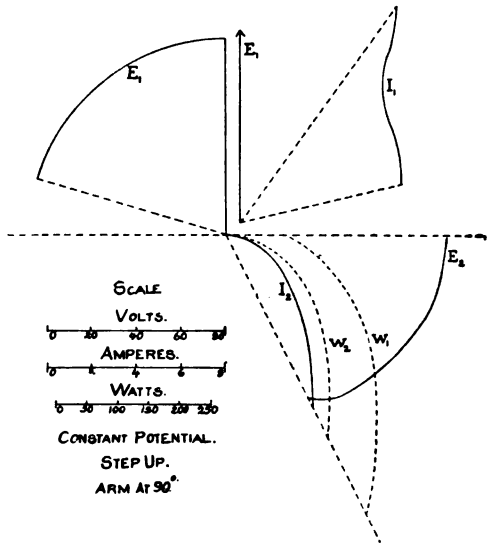

FIG. 17.

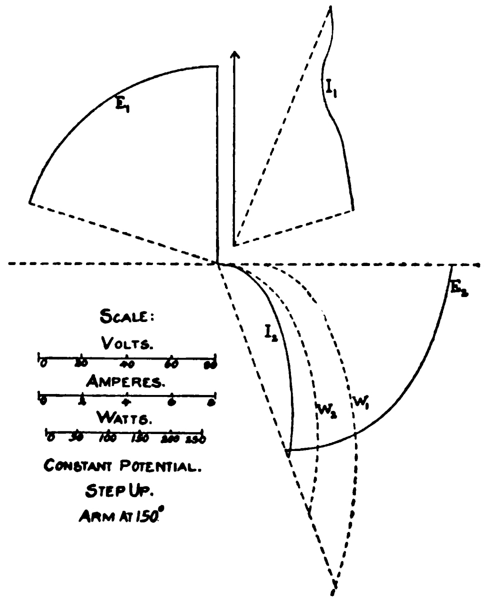

FIG. 19.

CONSTANT POTENTIAL EXPERIMENTS.

Runs were made with the transformer supplied with a constant potential of about 62 volts (square root of mean square value), with the movable tongue secured in the different positions 0°, 70°, 90°, 120°, 150° and 180° as before. The electromotive force of the generator was about 110 volts, but varied a little, so that it was necessary to maintain the electromotive force supplied to the transformer constant by adjusting the non-inductive resistances. Measurements were made as in the constant current experiments, and the values of the various quantities obtained as before. From this data, the polar diagrams Figs. 15-20 were constructed. In these the direction of the primary current is taken as vertical, fixed in direction, but varying in magnitude. The primary electromotive force is constant in magnitude, but varies in direction according to the value of the angle θ_1 between it and the fixed primary current. A diagram thus drawn does not show the

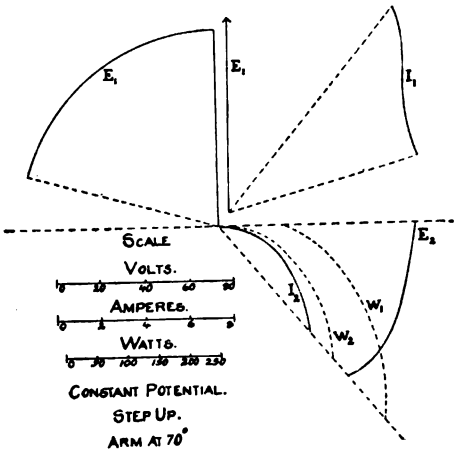

FIG. 16.

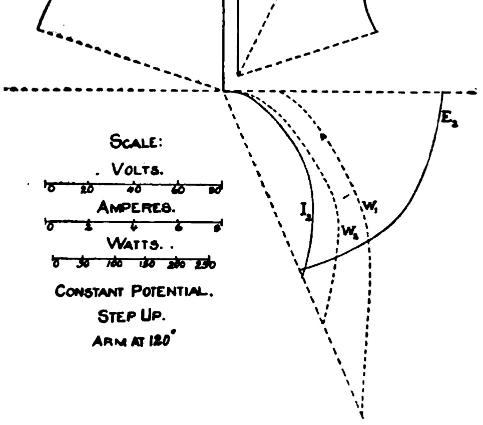

FIG. 18.

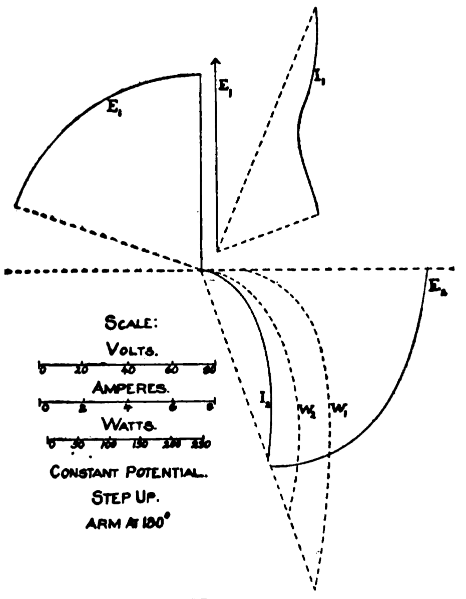

FIG. 20.

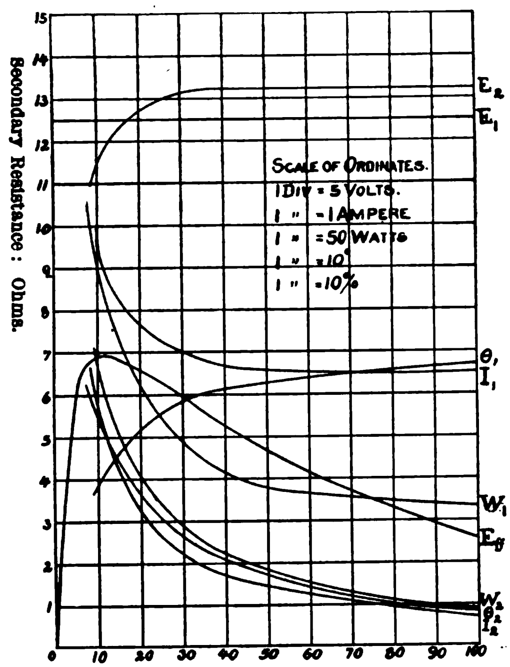
---

* For Parts I and II see ELECTRICITY Vol. V, Nos. 17 and 18.

† Read before the International Electrical Congress, Chicago.

changes in the magnitude of the primary current, and therefore an additional diagram is given in the upper right hand corner of each figure in which the primary electromotive force is constant both in magnitude and direction.

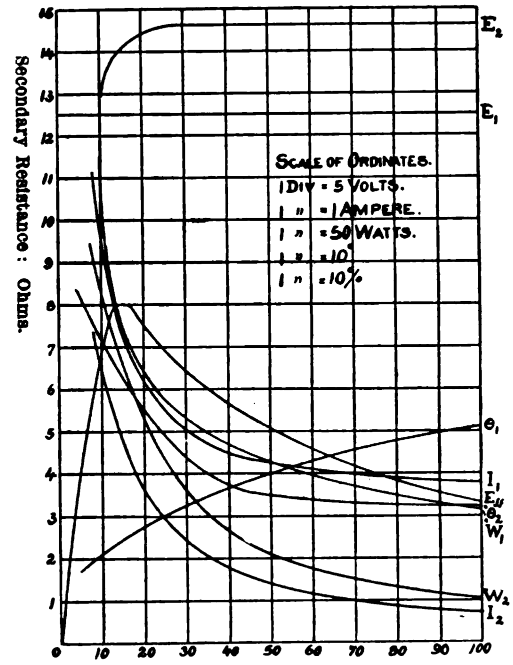


Constant Potential. Step Up. Arm at 0°

Fig. 21.

The locus of the primary current in this supplementary diagram shows clearly the changes in the magnitude of the primary current as well as its direction. As in all the polar diagrams in this paper, the loci are drawn to show the variation in the different quantities represented, caused by a change in the secondary resistance, the direction of the variation with increased secondary resistance being indicated by an arrow.

Figs. 21 and 22 are rectangular diagrams, drawn from the corresponding polar diagrams Figs. 15 and 20, representing the relative magnitudes only of the various quantities.



Constant Potential. Step Up. Arm at 100°

Fig. 22.

CONCLUSION.

When this investigation was undertaken with a view of experimentally developing the method of polar diagrams just described, it was with a little uncertainty as to whether the method would admit of ready practical application, and would give a clear exposition of the results obtained. It not only proves to be a convenient method for showing results, but tells the whole story in a comprehensive way, bringing out many points not otherwise shown. Furthermore, it proves valuable for comparison with similar theoretical work, based upon the assumption of harmonic currents, with which it agrees throughout, thus establishing the practical value of analytical treatment of problems with alternating currents.

The work was first taken up under the direction of the writer by Messrs. Berresford, Craft and Gherardi, as thesis[*] work at Cornell University. The investigation was conducted by them, and valuable assistance given by them in the preparation of this paper.

The curves here given are shown as representative and as illustrative of the method of showing the variation in certain quantities when one quantity is changed under certain conditions. Other curves were obtained, some of which showed the effects of the variation in the coefficients of induction, but those which are here described, showing the effects of a variation in the secondary resistance, have been given as being among the most interesting and instructive.

Cornell University, Ithaca, N. Y.

(Concluded.)

Legal Notes.

General Wing, of Auburn, Me., one of the bondholders of the electric street railway at Battle Creek, Mich., has begun proceedings for the appointment of a receiver. The city council has passed a resolution permitting the road to suspend operations for the winter, upon the understanding that it will resume May 15 with a good equipment.

The suit of the First National Bank against the City Electric Railway Company at Little Rock, Ark., for the sum of $110,341.61, an indebtedness which the street car company denies, has been referred to a master in chancery; as was also the case of Nick Kupferle, as trustee, against the same company, for $137,500 on a claim assigned by H. G. Allis for the benefit of the First National Bank. The street railway company deny this debt and set up that the First National Bank is indebted to them in the sum of $397,500.

Judge Andrews, of the Supreme Court, has ordered the dissolution of the National Electric Light and Power Company, of No. 120 Broadway, New York. The company was incorporated on November 20, 1879, with a capital stock of $300,000, and has ceased to do business since April, 1888, having been leased to another company. There are no assets and the only creditor is the United States Electric Lighting Company, whose claim is $4,551.

Personal.

Mr. Louis D. Brandeis, who is well remembered from his connection with the Beacon lamp case last winter, has given to Harvard University the additional sum of $1,000, to provide for the course in the law school for 1893-94 on the peculiarities of Massachusetts law.

Mr. James E. Hewes, formerly representative of the Baxter Electric Railway Motor Company of Baltimore, has left the above company and now holds a corresponding position in the recently reorganized Wenstrom Electric Company of Baltimore. The outlook for business in the South is very bright, and in Baltimore particularly so.

Mr. Walter C. McKinlock, secretary of the Metropolitan Electric Company, Chicago, has been confined to his house for some time on account of illness, but is again at work.

The Canal Experiment.

Electricity will Supplant the Mule.

The Difficulties Apparently all Overcome by the Westinghouse Company.

On Saturday, November 18, electricity was first applied for the propulsion of canal boats, and the demonstration was a thorough success.

Readers of Electricity are familiar with the progress in this important matter up to date, with its suggestion by Governor Flower, and the final designation of the Westinghouse and General Electric Companies to make the experiments. The test of the latter company's apparatus will not be made until next spring, and the Westinghouse Company have been the recipients of a good many columns of free advertising as the company which made the first successful experiment.

It was looked upon as a great event not only by the yeomanry in the vicinity of Brighton, where the trial took place, but by public spirited men throughout the State who have for a number of years been grappling with the canal problem in its various phases.

At 10 o'clock Governor Flower and party left Rochester for Brighton in two special cars placed at their disposal by President Beckley of the Rochester City Railroad Company, going on board the boat an hour later.

The banks were lined with an interested crowd of spectators from 3,000 to 4,000 in number.

The boat, formerly a steam propeller, was christened (after the gentleman who has had charge of the experiment) the Frank W. Hawley. The electrical apparatus had been carefully designed, and with the exception of the trolley itself no material changes will be required in practical work. The trolley used was underrunning, but the intention is to adopt an overrunning trolley, with flexible wire, allowing for the necessary lateral motion of the boat of from twelve to fifteen feet.

The trip was for about one mile, from lock 63 to lock 65, this section having been chosen because of its sharp curves and other features which represented all the main obstacles throughout the entire length of the canal.

The current was supplied from the circuit of the Rochester Railway Company. The trip was eminently a success, and was held by all present to practically demonstrate the feasibility of discarding mule power at an early date and substituting the trolley system.

The Westinghouse Company was represented by Messrs. George Westinghouse, Jr., Brayton Ives, Lemuel Bannister, Nikola Tesla, Paul D. Cravath, Albert Schmid, H. S. Clark, A. S. Morris and E. Chesrown.

Among the other gentlemen present were the following :

William S. Kimball, John N. Beckley, Frank S. Upton, F. W. Warner, Henry C. Brewster, Horace C. Brewster, David Hays, Charles P. Ford, Max Brickner, Bishop McQuaid, J. G. Cutler, Louis Wiley, Eugene T. Curtis, James W. Whitney, F. P. Allen, Senator Parsons, State Engineer Schenck, Deputy State Engineer Chapman L. Johnson, State Engineer-elect Campbell W. Adams, Superintendent of Public Works Hannan, Superintendent McDonough, Special Agent Halligan, Superintendent Miller, General Brinker, ex-State Engineer Bogart, Alderman Dewey, City Electrician Barnes, John Van Voorhis, J. C. Kalbfleisch, President Evan Thomas and Vice-President Alfred Romer, of the New York Produce Exchange; G. W. Balsh, chairman of the Canal Committee of the New York Produce Exchange; Dr. Coleman Sellers, president of the Niagara Falls Power Company; Francis Lynde, of Drexel, Morgan & Company;

---

[*] Thesis in Cornell University Library: "Effects of the Change of Reluctance in a Transformer."

Vice-President Wickes, of the Cataract Construction Company; W. B. Rankin, secretary and treasurer of the Cataract Construction Company; Anthony N. Brady, president of the Albany Electric Company; William Mertens, of Von Hoffman & Company, and Charles T. Lewis, of the Mutual Life Insurance Company.

As the boat was being raised in lock 64, Governor Flower made a brief address, in which he said:

"In 1829, when DeWitt Clinton started from Buffalo to Albany on a canal boat, he had a military company as an escort, but there was no electricity to move boats or transmit news. They sent the fact of his starting from Buffalo to New York by the successive discharge of cannon along the bank, and the time occupied was an hour and fifty minutes. The people gathered along the canal rejoicing at the improvement. Only forty tons of merchandise were sent from Buffalo to New York that year, but now 3,000,000 tons are sent through annually. I believe when this electric system is perfected there will be 12,000,000 tons sent from the West to the seaboard and without cost to the people. This experiment will give new life to the commerce of States along the great lakes and make the transportation on the Erie Canal equal to that on the Mississippi. I regard it as a great privilege as Governor to witness this experiment which marks the change from horse and mule power on the canal to electricity, which I believe will quadruple the usefulness of the canal."

A New Kind of Steal.

Two Young Men in Tacoma Make Money Rapidly.

T. H. Headrick and Orville Shaw, employed by the Tacoma Light and Water Company, have been arrested on a unique charge.

They had organized the Headrick-Shaw Electrical Company, and while retaining their positions with their employers, had been doing lighting on their own hook whenever they could get a contract for a building. Then they stole the wire, lamps, etc. (which they could do easily, having charge of this department), and connected their job to the circuit of the Tacoma Light and Water Company, or the Commercial Electric Company, a rival concern. They were reaping a harvest of $200 to $300 a month, when their bid on a new contract was so low as to cause an investigation of their source of supply.

What the Boys are Doing.

From reports made to the secretary of the Massachusetts Institute of Technology it is learned that of the 132 members of the class of '93, those who have secured positions are distributed among the various professions as follows: 15 electrical engineers, 9 civil engineers, 7 mechanical engineers, 5 chemists, 3 general and 2 mining engineers, 2 biologists, 1 chemical engineer, 1 geologist, 1 railroader, 2 in the employ of the United States Government, 1 traveler, 1 athletic trainer, 6 who are still students and 10 instructors.

It may be added that 85 per cent. of the members of this class did not smoke.

Electrical Quackery.

A singularly transparent attempt has been made in England to sail under false colors in the placing on the market of an "electric porous plaster." It is claimed that this plaster, "in addition to having undoubted electric energy, is made from a vegetable extract possessing valuable properties, and is the best porous plaster in the world." The plaster consists of a piece of coarse linen or canvas, 7½ inches long by 5 inches wide, perforated and having one side covered with the vegetable extract. Stuck on the "extract" are two very thin pieces of copper and zinc foil, about 1¾ inches long and 1⅛ inches wide, connected together by an attenuated strip of the zinc. The ends of this strip are simply placed about an eighth of an inch under the pieces of metal foil, no attempt at soldering or good contact being made. As the whole thing is not worth a cent and the selling price is 28 cents, there is a liberal margin of profit. A leading English electrical journal, in warning the public not to be duped by the artifice, shows that the copper and zinc connected by a strip of the latter metal, uninsulated, are in actual contact in the electrolyte, that is, on the humid skin, and adds: "We therefore have no hesitation in saying that the statement, 'when applied to the body real and effective electric force is generated,' is utterly untrue, so far as any operative effect on the body is concerned, and we trust that some steps may at once be taken to put an end to this misuse of electricity."

Boston Notes.

That little dispute or difference of opinion which recently sprang up between the Cambridge City Council and the New England Telephone and Telegraph Company, the result of which was the discontinuance of free telephone service for the city government, has not terminated as the city fathers hoped it might. The Telephone Company is inexorable. It refuses to continue the courtesy of free service as heretofore, consequently the city government is now having to pay at the rate of about $1,000 per annum for talking over telephone lines when transacting city business.

A project is on foot for extending the electric railway system of Haverhill, Mass., through to the neighboring manufacturing town of Manchester, N. H. As is well known a most extensive railway system unites Lowell, Lawrence, Haverhill and other manufacturing towns in that district. These roads are owned by a rich syndicate of Eastern capitalists. They are doing much to enchance the value of property in the territory through which they pass. It is felt that the system will not be complete until Manchester is united. Local boards of trade and other representatives are holding meetings to discuss the project and every indication warrants the belief that a deal will be soon consummated.

While the transaction is not yet concluded there appears to be a good deal of truth in the report about the Boston and Maine Railroad wanting to purchase the new foundry buildings erected by the General Electric Company on the marshes contiguous to the Saugus River. It is well known that the General Electric Company have found the foundry an expensive failure; and considering the financial straits which they are in and the chaotic condition of their affairs generally, which is fast becoming chronic, the chances are that within a few days the transfer of ownership will be completed.

Some time ago the Cambridge City Council appointed a committee to look into the question of municipal ownership of electric light and gas plants. That committee has been since busy collecting and tabulating data bearing on the subject. They have communicated with municipalities which now own and operate lighting plants, learnt all they could about the comparative costs, etc., etc. A few nights ago this committee presented its report, which is a very elaborate and exhaustive document, in which they summarize their unanimous opinion and make a recommendation that the city government should avail itself of the provisions of the Municipal Lighting Act of 1890. The matter is now being taken under further consideration.

Professor Elihu Thomson had a magnificent audience to listen to his brilliant lecture on "Lightning and High Potential Electric Currents" in Odd Fellows Hall, Lynn, Thursday evening. Prof. Thomson was able to produce most wonderful lightning effects with a current raised to an enormously high potential. The splintering and burning of wood as done by a real live thunder and lightning storm were done to perfection, though some of the audience got a little nervous, but were reassured when they realized that Prof. Thomson received the force of the powerful current into his body without being in the slightest degree harmed. The current for the high potential experiments was taken from the wires outside the hall, passed through a transformer which raised the 100-volt current to a higher voltage, and then a vertical transformer with a core surrounded by many turns of copper wire closely wound, and a 20,000-volt current was obtained.

Discharging more hands and reducing wages to the extent of 10 per cent. continues to be the prevailing order of things at the factories of the General Electric Company. Consternation and dread seem paramount among the employees who regard with fear and dismay the rapid approach of winter, which means for many pinching hard times and blank uncertainty as to the future. The 10 per cent. reduction goes into effect Monday morning.

Outside the General Electric Company there is not a single electrical manufacturing concern in or about Boston that is not busy, and in some cases actually more than busy. We know of one firm which quoted so ridiculously high a price for a contract offered that it was refused. The company didn't want the job.

General News.

What is Going on in the Electrical World.

St. Charles, Mo.—The city electric light plant is to be reconstructed.

Wallingford, Conn.--The electric road to Meriden is nearing completion.

Howard City, Mich.—The people here are talking in favor of getting electric light.

Portsmouth, Ohio.—The formal opening of the electric street railway took place last week.

Columbus, Ohio.—The electric street railway between Columbus and Worthington has been completed and cars will be running in a few days.

Omaha, Neb.—One hundred and fifteen miles of the telephone line between Omaha and Norfolk are now completed. The whole distance is 160 miles.

Chester, Pa.—The Arnold Electric Company, which made an assignment last week, will resume under the assignee, the Delaware County Trust Company.

Lansing, Mich.—The question of bonding the city for $85.000 for electric light and bridge purposes has been settled affirmatively by popular vote.

Los Angeles, Cal.—The San Bernardino Electric Light and Power Company has been awarded the contract for lighting the city for the next three years.

Rochester, Minn.—The Western Electric Company of Chicago, which has the contract for putting in the new electric light plant, is pushing the work with energy.

Hanover, Pa.—The Hanover Electric Light Company is getting matters into such a shape that within the next month the town will be lighted by electricity.

Hartford, Conn.—The Hartford, Manchester and Rockville Electric Railway Company was organized here last week. No action was taken in regard to building the road.

Northampton, Mass.—The Northampton Electric Light Company has voted to issue $60,000 6 per cent. bonds on its new building, and to sell the old property on Masonic street.

Sioux City, Iowa.—Judge Gaynor has signed a final order in the cable road receivership matter authorizing the receiver to contract to change the cable line into an electric road.

Springfield, Mo.—The city council has instructed the clerk, Mr. Noe, to correspond with various electric lighting experts about the making of plans and specifications for a plant to be put in by the city.

Meridian, Miss.—The Edison Electric Light and Power Company's plant has been offered by the assignee to the city for $14.500, and the probability is that the city will take it at that price and operate it in city lighting.

Adamstown, Pa.—At a meeting of citizens here a committee of ten was appointed to solicit subscriptions toward the construction of an extension of the Reading and Southwestern Electric Railway from Mohnsville to Adamstown.

Newington, Conn.—An electric railway running through this place, and connecting it with New Britain and Hartford, is a topic of the greatest interest here, and several meetings of prominent citizens have been held to further the scheme.

San Francisco, Cal.—A number of electric roads are being built or projected to the Mid-Winter Fair Grounds. The Southern Pacific's spur track to the ocean beach, contiguous to the grounds, is to be turned into an electric road.

Pawtucket, R. I.—Of the nine street car lines coming into or passing through this city seven are now operated by electricity and the two still depending upon horses as motive power are the Broad and Cottage street routes, and they expect to change to electricity in the spring.

Ambler, Pa.—The taxpayers of this town have held a meeting at which it was decided to submit the question of lighting the town by an electric plant to be owned by the borough to a vote of the residents. The town has heretofore been lighted by a private corporation.

Carmi, Ill.—The city council has granted a franchise to Jerome Wallis, George Wurt, Jr., and Charles Faulkner, of this city, to establish an electric light plant here. The city contracts for thirty arc lights of 2,000 candle power at $90 per arc, the contract to last ten years.

Long Branch, N. J.—The Gas and Electric Companies have consolidated. The company will be incorporated under the new name of the Long Branch Lighting Company. The officers elected are : H. E. Gawtry, president; C. Henry Irwin, secretary, and George N. Curtis, treasurer.

Toronto, Can.—Electrician Davis, of the Street Railway, seems to have had no hesitation in saying this of his road: "This is the best electric railway in America. We have better cars, better motors, better rails, better roadway and a better service than any place in America."

Salem, Ohio.—The Salem Electric Light and Power Company has just closed a contract with the city authorities to put up and operate for ten years one hundred 1,200 c. p. arc lights, to displace the 325 incandescent lamps of 25 c. p. which the company has hitherto furnished. The new system is to be in operation by February 1 next.

Conshohocken, Pa.—The Norristown, Bridgeport and Conshohocken Traction Company, of which James P. McQuaid is president, has leased the line of the Montgomery Railway Company, extending from Bridgeport to Matsunk for 999 years. It has also offered to lease the Norristown Passenger Railway Company's lines. Both leases guarantee interest on the stock and bonds.

Montreal, Can.—The Standard Light and Power Company has sold to the Montreal Street Railway Company the Bickerdike Street Railway charter, which includes a thirty-years' exclusive street railway franchise for St. Henri and St. Cunegonde. The company by the purchase of this charter has now exclusive rights west of Montreal to Lachine, east to Longue Pointe and north to the city limits.

Gravesend, N. Y.—This town, which has lately attained unenviable notoriety in politics, has been slumbering in darkness hitherto, but will soon have electric lights, as the plant is fast nearing completion. The boiler and engine house is about furnished with engines, dynamos and boilers. Poles and wires are put up in all parts of the town, and it is expected that by December 1 the town will be lighted by electricity.

Brooklyn, N. Y.—The Brooklyn, Bath and West End Railroad has discarded steam locomotives and substituted electricity as a motive power. The cars will be run in trains and electrically heated and lighted, thus affording every comfort and convenience to patrons.—Details are nearly completed, it is said, for the consolidation of the Long Island Traction Company and the Brooklyn Traction Company, and before many mouths pass it is expected that all the roads in the city will be under one management.

Nashua, N. H.—The project of connecting Nashua with Manchester, Haverhill and other towns by electric railway has been lately discussed at meetings attended by delegates from the towns interested, and there seems every probability that it will be carried out successfully. At a meeting held last week in this city speeches were made in favor of immediate construction of the road by President Sanders of the local board of trade; Prof. Campbell, principal of the Pinkerton Academy, Derry; G. D. Bartlett, of Derry; Gilman Corning, of Salem, N. H. ; A. K. Welcomb, of Chester, N. H., and G. W. Dobbins, of Plaistow.

Paterson, N. J.—The stockholders of the Paterson and Little Falls Consolidated, the Paterson and Passaic, and the Passaic, Rutherford and Carlstadt Electric Railway Companies have agreed to consolidate the three roads. The name of the consolidation will be the Paterson, Passaic and Rutherford Electric Railroad Company. The officers of the new company are : President, Charles A. Johnson, Brooklyn ; vice-president, James A. Morrisse, Paterson ; second vice-president, Francis C. Van Dyke, Paterson; treasurer, Louis Fitzgerald, New York; secretary, John J. Scanlan, Paterson. The system when complete will connect Jersey City and Paterson.

Chicago.—The city council has passed the ordinance giving the Mutual Electric Light and Power Company "permission and authority to erect and maintain and use one or more systems of electric conductors above or under ground for the transmission of electric light, power and heat, or either of them, in the streets, alleys and public ways of the present limits of the city south of the centre line of Thirty-ninth street, and of said streets extended west to the city limits and west of the centre line of State street." The ordinance prohibits the company from furnishing power for any surface railroad, and provides that but one system of conduits may be laid in any street.—At the same meeting of council resolutions were read and referred to the finance committee recommending the purchase of dynamos, boilers, etc., from the Exposition exhibits, in order to extend as fast as possible the municipal electric street lighting plant.

New Orleans, La.—The City Railroad Company and the Traction Company have combined their interests on the following basis: The Traction Company, in consideration of $3,000,000 worth of 5 per cent. first mortgage gold bonds and $500,000 worth of capital stock, issued as full paid and not liable to assessment, would pay for and deliver to the railroad company a fifty years' extension of its franchise, retire its present bonded indebtedness of $423,000, and entirely rebuild all its tracks and equip the road for service with the trolley system of electric locomotion, doing from time to time all such work as may be required of the road by city ordinance, and keeping the road fully equipped. The Traction Company guarantee annual dividends of 8 per cent. after January 1 next. The mortgage to be recorded against the road to contain a provision for a sinking fund sufficient to retire the entire amount of the mortgage within fifty years.

The Armature Bell.

The Armature Bell, illustrated herewith, is a new device for the efficient and reliable operation of electric front door bells, call-bells, annunciators and door-openers, and is also specially adapted for use in watchmen's clocks and like purposes.

For residences, flats, apartments and hotels it is well adapted, no batteries of any kind being required, and the uncertainty, expense and trouble which attend the use and care of electric batteries being avoided.

The Armature Bell has nothing to get out of order, also replaces the old-fashioned door-bell, which causes more or less trouble as the wire stretches or breaks, as the case may be, whereas this bell can be relied upon for constant and efficient service, which is not the case where batteries are used, these being liable to give out at any moment without warning. The importance of this, especially in the case of front door bells, will be apparent to all users.

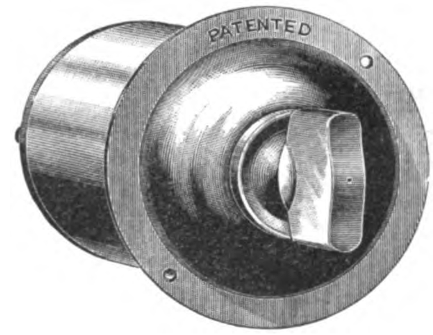


Fig. 1.

Cut No 1 represents a Call Armature Bell which is adapted for hotel, private house, apartment, office or factory use. A half turn of the key either to the right or left will generate instantly current sufficient to ring the bell. The armature occupies a space about 1⅝ inches in diameter and about 1¾ inches in depth, and while being a substitute and doing away with the use of batteries can be attached to wiring now in use without necessitating any rewiring. In the mechanical construction o the Armature Bells the best material has been used in order to combine in the highest degree durability with efficiency.

Cut No. 2 represents the Straight Pull Front Door Be with armature attachment. This is for direct work fo door bell use, being constructed on the same principle as the Call Bell, only instead of a key turning to the right or left, the usual straight pull knob is used, which revolving the armature in the field, generates a strong electric current to a bell located in any part of a building.

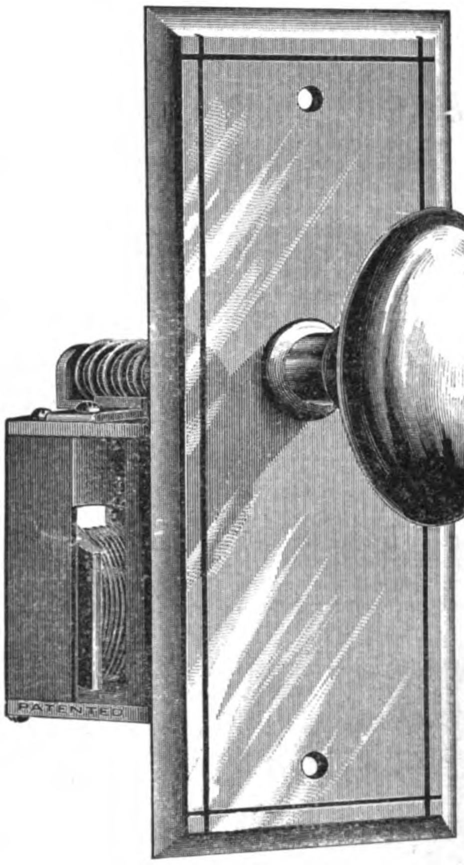

Fig. 2.

Cut No. 3 represents the bell used in connection with these armatures, which combines also the elements of simplicity and certainty, there being no springs or contacts requiring adjustment and liable to get out of order.

This system can be applied by manufacturers to watchmen's clocks, door-openers, annunciators, etc., now in use, at only a slight additional outlay, the same system of wiring being used as at present with the batteries.

The advantages of the Armature Bell are compactness, durability, efficiency and absolute reliability for giving uninterrupted service.

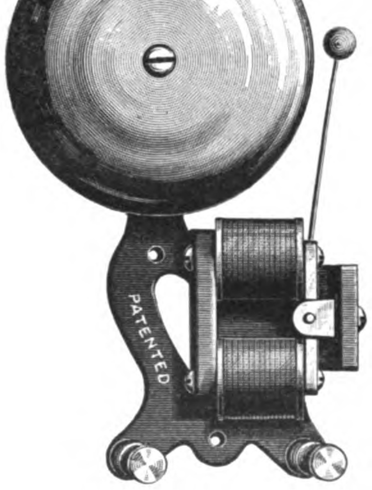

Fig. 3.

While the original cost is perhaps somewhat higher than that of the battery outfit, the cost and annoyance of renewals of batteries in connection with the old system is avoided, and when once installed these Armature Bells have the advantage of requiring no further attention or expense.

These Armature Bells are made by the **Armature Bell Company, 216 High street, Newark, N. J.**

The Stirling Boiler.

Office of Jno. J. Shipherd, Vice-President,
Cleveland, Ohio, Sept. 23, 1893.

FREDERICK E. BRUCE,
Agent Stirling Company, Cleveland.

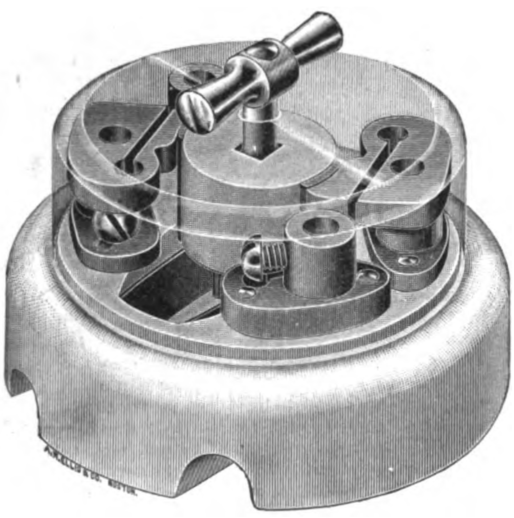
Dear Sir: Replying to your request as to the relative result both as to efficiency and economy between the Stirling Boiler and the Babcock & Wilcox, working side by side in our street railroads of Cincinnati, Newport and Covington, would say; at Cincinnati we have 500 H. P. Stirling Boilers and 564 H. P. Babcock & Wilcox Boilers. The Stirling Boilers, while of less heating power rating, will run our three 500 H. P. compound condensing engines with one-third less fuel than the Babcock & Wilcox.

We prefer the Stirling Boiler on account of its simple construction, there being no numerous tube caps to remove; and we find the Stirlings keep free from scale, while the B. & W.'s are constantly requiring attention. We are satisfied that the Stirling has better disengaging surface and furnishes dryer steam. Our use of the Stirling Boilers at the Evansville Street Railroad led us to the adoption of this boiler in our additions, in preference to the B. & W., which we have used for about four years, and not with the result expected; the question of difference in price not entering as a factor, but we believe should be in favor of the Stirling. We cannot hesitate to recommend them to anyone desiring boilers. I remain yours very truly,

JNO. J. SHIPHERD, Vice-President,
Cincinnati, Newport and Covington Railway Company,
Evansville Street Railroad.

The Iona Double Pole Switch.

The double pole switch which we illustrate below is already a great favorite with the trade, and although smaller than any on the market, it has a greater carrying capacity than many twice its size. The switch is simple in construction, convenient to wire, and is durable and reliable. Every switch is marked "on" and "of," thus showing at a glance its actual condition.



THE IONA DOUBLE POLE SWITCH.

The above is being manufactured and placed on the market by the Iona Manufacturing Company, 336 Congress street, Boston, who have just issued a catalogue showing the above and other specialties which they manufacture. This they will mail on application.

Commercial Notes.

The Auburn Electric Motor Company, Auburn, Me., reports a lively business. The prospect is for sufficient work to keep the full force employed all winter.

The Metropolitan Electric Company, Chicago, have just received a boatload of electric light carbons, consisting of ½ x 12 and 7-16 x 12, and ½ x 7 and 7-16 x 7, both plain and plated. This will enable them to fill their orders without any delay, and handling them in such large quantities enables them to make factory prices.

INCORPORATIONS.

The Colebrook Electric Light Company (incorporated in New Hampshire), principal office, 209 Washington street, Boston, Mass.—to furnish electric light, heat and power to the inhabitants of Colebrook and vicinity. Capital stock, $12,000. Promoters: Henry F. Holland, Clarence F. Eldridge, both of Boston, Mass.: W. E. Drew, Colebrook, N. H.

The Carbondale and Forest City Passenger Railway Company, Carbondale, Pa.—to construct and operate an electric railway in Lackawanna County. Capital stock, $150,000. Promoters: Jno. W. Aitken, Edwin Corey, J. M. Nicol.

The Anthracite Electric Railway Company, Pottsville, Pa.—to construct and operate an electric railway in Schuylkill County, Pa. Capital stock, $500,000. Promoters: Jesse Newlin, Edw. S. Newell, Lewis B. Walker.

The Penn Traction Company, Philadelphia, Pa.—to operate passenger railways by cables, electrical appliances, etc. Capital stock, $10,000. Promoters: Isaac M. Thomas, Geo. W. Shonk, John B. Yeager.

The Manayunk Passenger Railway Company, Philadelphia, Pa.—to construct and operate an electric railway in Philadelphia. Capital stock, $12,000. Promoters: Fletcher Pearson, James Rawle, John T. Dunlap.

The Anderson Electric Company, Anderson, Ind.—to supply electric light for city and public use. Capital stock, $50,000. President and treasurer, Charles L. Henry; secretary, L. M. Cox; directors: E. E. Hendee, J. W. Wild, E. M. Campbell.

The Pittsburg Electric Company, Pittsburg, Pa. Capital stock, $5,000. Directors: James A. Curry, Wilkinsburg; William H. Warwick, Bellevue; Robert A. Johnston, William M. Gillespie, Pittsburg, and Edwin L. Allen, Allegheny City.

The Whitestone and College Point Railway Company, Flushing, L. I.—to build a double track surface road in Flushing. Capital stock, $60,000. Incorporators: Israel J. Merritt, Jr., Moses Worms, Oliver Taff, Diederich Steffens and Harvey Peace, all of Whitestone; John J. Delaney, College Point: Walter C. Foster, Long Island City; Harry D. Loux, Mount Vernon; John F. Anderson, Bay Side, and others.

The Baker Lamp Electric Company, Portland, Me.—to manufacture and deal in arc and incandescent electric lamps, etc., under letters patent granted to Elbridge Baker, of Winchester, Mass. Capital stock, $400,000. Promoters: F. A. Whiting, Lowell, Mass.; Chas. A. Stellman, West Newton, Mass.; B. C. Mudge, Lynn, Mass.

The Baltimore Electric Company, Baltimore, Md.—to do a general electrical business. Capital stock, $10,000. Incorporators: Robert C. Rhodes, Phœbus H. Alexander, Charles C. Rhodes, Clarence C. West and Frank V. Rhodes.

The Cataract General Electric Co.—for the purpose of purchasing and selling electric power and the negotiation of contracts for the production, distribution and use of such power within the county of Monroe, N. Y., and in such other places on or near the lines of railroad entering the county as may furnish a market for such power. The principal office will be in New York City. Capital stock, $8,000. Directors: William Hortens, Thomas C. Platt, Commodore P. Vedder, Frank W. Hawley and Charlton T. Lewis, of New York.

The Brooklyn, Bergen Beach and Canarsie Railroad Company, Brooklyn, N. Y.—to construct a street surface railroad about nineteen miles in length to be operated by electricity. Capital stock, $200,000. Directors: Thomas Adams, Jr., and Louis R. Adams, of Brooklyn; Percy G. Williams, of New York City; Frederick Rosebush, of Ozone Park, Henry E. Hughes, Charles E. Morrell and F. W. Lemken, of Canarsie; Daniel I. Wright and Alexander Stafford, of Flatlands.

The Marble City Electric Company, Rutland, Vt.—to manufacture, sell, furnish and supply electric light and power for public and private use, etc. Capital stock, $50,000. Promoters: Jno. A. Sheldon, F. M. Butler, Harry M. Bates, Jas. Caruthers, Rutland; Harry B. Thayer, New York City; Jno. M. Jackson, Chicago, Ill.

The Commercial Electric Engineering Company, Detroit, Mich.—to do general electrical engineering and contracting, etc. Capital stock, $50,000. Promoters: Jos. B. Moore, Geo. E. Fisher, Orville D. Chase, all of Detroit.

The San Francisco Bonet Electric Tower Company, Chicago, Ill.—to build and operate electric tower in Court of Honor on grounds of California Mid-Winter International Exposition. Capital stock, $150,000. Promoters: Leo Bonet, Marie Dubois, W. H. Munnich.

The Metropolitan Electric Company, Chicago, Ill.—to manufacture and deal in electrical apparatus and supplies, etc. Capital stock, $300,000. Promoters: Edw. S. Elliott, John E. Campbell, Henry A. Ritter.

The American Stethophone Company, Chicago, Ill.—to manufacture stethophones, lines, exchanges, etc., and deal in electrical instruments, appliances, etc. Capital stock, $5,000,000. Promoters: R. D. A. Wade, John B. Phelps, Walter Olds.

The Boardman River Electric Light and Power Company, Traverse City, Mich.—to manufacture and sell electricity for light, heat and power, etc. Capital stock, $100,000. Promoters: Loraine K. Gibbs, Mayfield, Mich.; Jas. S. Hodges, Jas. L. Gibbs, Traverse City.

The Reed Electric Company, Camden, N. J.—to manufacture and sell storage batteries and other electrical apparatus and devices. Capital stock, $500,000. Promoters: Gustav Stahl, Philadelphia; Chas. J. Reed, Wm. A. Robbins, Camden.

The Belmont Manufacturing Company, Chicago, Ill.—to manufacture and deal in vegetable and mineral compounds for illuminating purposes, electric car renovator, furniture polish, carpet renewer, etc., etc. Capital stock, $250,000. Promoters: A. T. Robinson, Chas. F. Knowlan, I. K. Hall.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 7, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

507,997. Electric Locomotive. Joseph I. Conklin, Brooklyn, N. Y. Filed Dec. 8, 1892.
508,083. Electric Railway System. Carl T. B. Brain, Liverpool, England. Filed Aug. 29, 1891.
508,089. Safety Apparatus for Electric or Other Street Railway Cars. William Cox, Hamilton, Can. Filed Dec. 31, 1892.
508,104. Conduit Railway Trolley. Herbert A. Goreham, Decatur, Ill. Filed Jan. 31, 1893.
508,199. Closed Conduit Electric Railway. Otis B. Benton, Cleveland, Ohio. Filed May 31, 1893.
508,236. Conduit Electric Railway. Jacob Pawolowski, Cincinnati, Ohio. Filed Feb. 27, 1893.
508,373. Electric Car Attachment. Isaac H. Davis, South Butte, Mont. Filed June 15, 1893.
508,388. Electric Railway. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Electric Car Company of America, same place. Original application filed Nov. 30, 1886. Divided and this application filed April 21, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

507,978. Incandescent Electric Lamp. Craig R. Arnold, Sharon Hill, Pa. Filed Feb. 28, 1891.
508,006. Electric Light Fixture. Larsen Filstrup, Chicago, Ill. Feild Aug. 12, 1891.
508,314. Carbon Holder. Clark C. Hill, Newport, R. I. Filed Jan. 18, 1893.
508,343. Extension Electrolier. Alvin Rivenburgh, Greenfield, Iowa, assignor of one-half to Frank David Mears, same place. Filed July 27, 1893.
508,392. Electric Arc Lamp. Benjamin Adair and Charles H. Klewer, Denver, Col. Filed March 6, 1893.

DYNAMOS, MOTORS, ETC.

508,000. Electric Motor Apparatus. John C. Davidson, Prince's Bay, N. Y., assignor to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed May 2, 1893.
508,129. Electric Motor. William P. Carstarphen, Jr., Denver, Col. Filed Nov. 18, 1892.
508,188. Alternate Current Electric Motor. William Stanley, Jr., Great Barrington, Mass., assignor, by mesne assignments, to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Oct. 23, 1888.
508,208. Regulator for Dynamo-Electric Machines. Albert M. Cullingworth, New York, N. Y. Filed May 6, 1892.

BATTERIES.

508,069. Polarity Switch for Secondary Battery Systems. Allen H. Whiting, New York, N. Y. Filed June 1, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

507,983. Automatic Signal for Trunk-Lines of Telephone-Exchanges. Oro A. Bell, Brooklyn, N. Y., assignor to Western Electric Company, Chicago, Ill. Filed Feb. 7, 1893.
508,054. Multiple-Switchboard System for Telephone-Exchanges. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb. 7, 1893.
508,214. Telegraph-Key. John R. Frank, Minneapolis, Minn. Filed May 29, 1893.
508,255. Telephone-Circuit. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed Jan. 31, 1893.

ALARM AND SIGNALING APPARATUS.

508,215. Electric Time Signaling System. James H. Gerry, Brooklyn, N. Y. Filed Aug. 10, 1892.
508,356. Railroad Signal System. George L. Thomas, Brooklyn, N. Y., and Edward C Seward, Montclair, N. J.; said Seward assignor to said Thomas. Filed July 1, 1893.

MISCELLANEOUS.

508,050. Circuit-Breaking Device for Reciprocating Electric Machines. Charles H. Richardson, Philadelphia, Pa. Filed June 2, 1892.
508,068. Lightning-Conductor. Gustav T. Walch, Kaufbeuren, Germany. Filed Feb. 21, 1893.
508,084. Diaphragm Used in Electrolytical Processes. August Breuer, Iserlohn, Germany. Filed September 14, 1892.
508,262. Electric Tool. George H. Williams, New York, N. Y. Filed Dec. 28, 1892.
508,284. Electrically-Heated Soldering-Iron. Charles L. Coffin, Detroit Mich., assignor to the American Electric Heating Company of Maine. Filed Dec. 10, 1892.
508,295. Electric Cable. Henry W. Fisher, Pittsburg, Pa., assignor to the Standard Underground Cable Company, same place. Filed Aug. 7, 1893.
508,322. Electric Regulator and Switch. Walter N. Jones, Jr., Petersburg, Va. Filed July 20, 1893.
508,370. Covering Electric Conductors. William A. Conner, Pittsburg, Pa., assignor to the Standard Underground Cable Company, same place. Filed Dec. 6, 1890.
508,380. Electric Rotary Flue-Cleaner. Fulton Gardner, Chicago, Ill. Filed Feb. 23, 1893.

To Inventors and Others.

United States and Foreign Patents Procured.

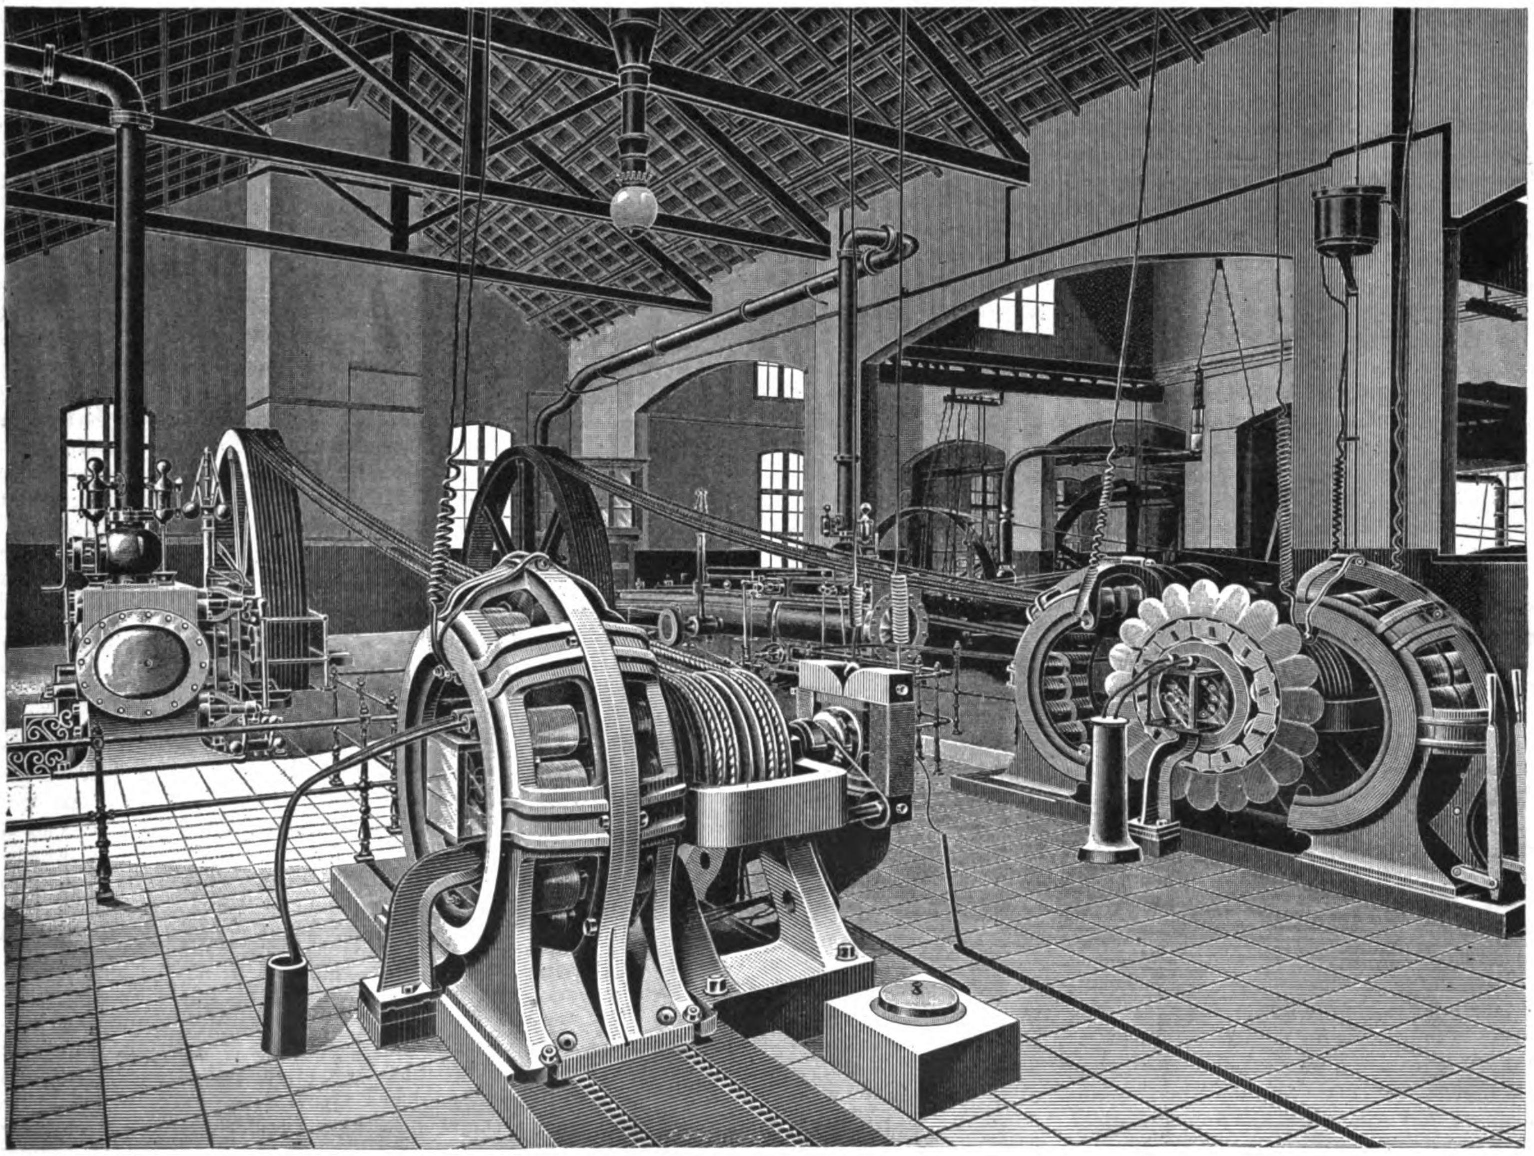
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. NOVEMBER 29, 1893. CHICAGO. No. 20



THE BARCELONA CENTRAL STATION. (SEE PAGE 234.)

The Barcelona Central Station.

The Central Station of the Barcelona Electric Lighting Company, which is illustrated in our Frontispiece, is on the high tension alternate current system, the dynamos being of the Ferranti type.

The capacity of the station is equal to 11,000 lamps of 16 candle power, and it serves both arc and incandescent lighting.

The Buffalo Electrical Society.

"Electricity at the World's Fair" was the subject of an interesting lecture delivered before the Buffalo Electrical Society at its last meeting, held November 16. The society's president, Mr. Philip K. Stern, was the lecturer. He gave a general outline of the Electrical exhibits at the Fair, touching on those of scientific importance, and others equally important on electrical engineering.

The attendance was large and there promises to be a revival among local electricians this winter. President Stern, Frank Kitton and Frank C. Perkins were appointed a committee to secure, if possible, for the next meeting Prof. George Forbes, the Electrical Engineer of the Cataract Construction Company. The secretary has written to Mr. Nikola Tesla with a view to making arrangements for a lecture in the near future.

Modern Uses of Electricity—II.

MEASUREMENT OF ELECTRICITY.

The second lecture of the course was delivered at Boston, Mass., on Thursday evening and was on the subject of "Measurement of Electricity," in introducing which Prof. Cross said that it was between 1820 and 1825 when Ampere and Arago discovered the effects of a wire being placed in a magnetic field, which was to produce a current of electricity.

In 1830 Michael Faraday was led by his speculations and experiments to believe that with a wire in a magnetic field there ought to be some way of generating a current, and this he accomplished.

He worked a long time on his experiments, and from the results he achieved the dynamo of to-day has been evolved. He found that by taking a ring of iron and winding several coils of wire round it of varying thickness and direction, as well as of a different number of turns, he could make a current to flow through one of the coils, discovering at the same time that there was a temporary current set up in the next coil though flowing in an opposite direction. The coil through which flowed the current connected with a battery he called the primary coil, while that in which was set up temporarily the other current he called the secondary coil. After much hard work Faraday found that the secondary or temporary current was generated just when the primary circuit was made and broken, "or make and break" as it is called. By means of an oblong magnet, between the sides of which was suspended a compass needle connected by wire to a battery, Prof. Cross showed the deflection of the needle of the galvanometer in opposite directions just according to the make and break of the circuit. Several other of Faraday's experiments were utilized to demonstrate the action of the current. The changes that occurred in the flow of an electric current produced a difference of potential. The direction of an electric current is very easily discovered by the principle that whenever a current traverses a circuit in a magnetic field the circuit will tend to expand in every direction, and so includes the greatest possible number of lines of force passing through it. The effect of any motion in a circuit is to produce a motion. Whenever the conductor moves in a magnetic field it tends to produce a current that hinders that current.

According to the law of Lenz an induced current flows in a direction opposite to that of the hands of a watch when the current is increasing, while it moves in the opposite direction when the current is decreasing in quantity.

In illustrating this fact the lecturer made some further experiments with a powerful magnet connected with a battery, also using a loop of iron and the earth as a magnet; beautiful effects were produced in the galvanometer according as the loop was held as near as possible in the earth's plane or at angles of 80° and 160° to it.

It was not to be thought that these induction currents were always of a temporary character. Formerly it was thought that these currents were of brief duration and consisted of pulsations only, but that was not according to facts, for such induction currents were sometimes very strong and of continuous variations.

By using an alternating current dynamo a wave-like motion was produced in the current, which in other words meant that the direction of the current was reversed—that is to say, the lines of force were reversed.

This was illustrated by using a machine giving about 125 alternations per second. This was connected to a large coil which produced an induced current of sufficient strength to cause an incandescent lamp to light up. The use of such currents had been utilized in the modern electric gas lighting appliances. By taking two wires directly from a battery a current is set up in two coils of wire so connected that the vibrations are sufficiently numerous to enable the gas to be turned on and ignited at the same time.

Prof. Cross then continued his lecture by making a series of interesting experiments illustrative of the discoveries of Faraday, and showing the effects of various objects being placed within the influence of powerful magnetic fields.

ELECTRICAL UNITS.

Prof. Cross's third lecture in the course at Huntington Hall attracted another large and interested audience. It was a continuation of the subject of the previous lectures, the "Measurement of Electricity." The lecturer said that as electrical units have been determined quite recently it was useful to discuss the terms now in common use in this country for the measurement of electricity. As to the derivation of the units that had been adopted and now employed, they were of a purely scientific character. The employment of them is now so general that a consideration of them could not be omitted from a course of lectures on electricity. We read occasionally of the welding of rails by electricity, the execution of criminals, and other uses of the current, so that we ought to have some notion of the definitions technically employed.

The history of the derivation of electrical units is very interesting, for it shows the way in which they have been evolved. The necessity for them has been such that the scientific men of the world have found themselves, as it were, compelled to adopt them. Electrical apparatus have been adopted from time to time, as have electrical terms, only to be changed from time to time.

The derivation of these units goes back some fifty years, though the full development of them originated in the behavior of the first Atlantic cable, which was laid successfully in 1860 and after a few years gradually fell into disuse. The failure of this and other similar enterprises led to the appointment of a Parliamentary Commission, which sat for months and examined all the prominent scientists and practical engineers in England and from other countries. By this means they ascertained about all that the scientific men understood or knew on the subject. It became manifest then that the adoption of some units was imperative for electrical measurement, so that contractors could be held to their undertakings. The British Association appointed a committee to look into the matter and adopt a series of units such as are now in use all over the world.

In considering this matter, then, it will be necessary to fix upon certain things or conditions to which the units will apply. These are among others bulk, strength, capacity, time, etc. In measuring electricity the French use a resistance of so many kilometers of ordinary telegraph wire. The Germans use a Siemens mercury resistance, which consists of a column of mercury at a temperature of the freezing point of water. Of course all these are quite arbitrary processes.

There are standard units in use for various purposes, and all alike useful for what they stand. In the first place there is the meter, the 100th part of which is called a centimeter. Prof. Cross then showed a bar composed of iridium and platinum, the same being marked off in meters and centimeters when the bar was at a temperature of the melting point of ice.

The standard unit for mass or bulk was a *gramme*. In allusion to the unit of time, the lecturer said the *second* was so used the world over.

The unit of force showed that an object would be heavier at the earth's poles, while the same substance would be lighter at the equator than it was in the lecture room. To secure accuracy of measurement the fractional part of a gramme must be used.

The lecturer proceeded to show how to measure the magnetic strength of dynamo fields, and illustrated how the poles of a magnetic field tended to move along the plane of the earth's motion.

The method of measuring the force in a magnetic field is analogous to the modus by which the force of gravitation, or the force of gravity, is ascertained. That is done by the swinging of a pendulum at different points of the earth's surface. A pendulum swinging at a certain rate in Boston would move faster if nearer the earth's poles and slower if nearer the equator; in like manner the strength of a magnetic field could be ascertained or measured accurately.

In considering electrical units it was necessary to define a unit. The unit of strength was defined as being that current a centimeter of whose length acts with the force of one dyne upon the poles of a magnet, and this is ascertained by the use of a tangent galvanometer. This unit has been derived from and agrees with Ohm's law, first made known to the world in 1827. From this it can be inferred that a thing we can most readily standardize is something that can be kept without danger of loss. In measuring electric strength or force we must have a standard resistance, and this has been accomplished by a coil of wire of some kind of metal. This wire can be made of a definite diameter and used as a standard under all conditions and circumstances.

Prof. Cross then described the simplest method of determining the unit of resistance known as the British Association method, which is an ideal rather than a practical method. He said if we can produce a known electromotive force in any way so as to estimate its value, then the strength of the current can be accurately measured. To calculate electromotive force a commutator is used which induces the current always to flow in the same direction, and from our knowledge of the strength of the earth as a magnetic field we can get at what we desire to know.

The unit of pressure is known as the *volt*, which is the absolute resistance of pressure or electromotive force. An *ampere* is the unit of mass, the *coulomb* the unit of quantity.

The resistance coil wherewith to test or measure electrical currents was first constructed by a committee of the British Association, but through some mistake it was found to be incorrect, and so more accurate ones had to be made. At the present time what is known as the Clark cell, which is a curious kind of battery, is used as the unit of electromotive force. It has been found by scientists that silver is the best metal for standard measuring purposes and it is used by many for that purpose. There are also, said the lecturer, standards of self-induction. If a coil or ring of iron be inserted in a circuit the current is cut down by a definite amount and the unit is like other units by means of which one can accurately measure the current. For this purpose no unit had been adopted until the recent congress at Chicago, when it was finally decided to give to the unit of self-induction the name of *henry*, after Prof. Henry, of Princeton College, who first discovered self-induction.

In order that his hearers might not be wearied with the numerous definitions of units, the lecturer said, he would pass on and say a few words about electric meters, by means of which the quantity of electric current a person was using in a commercial way could be ascertained. It was clear that as soon as electricity came to be supplied regularly it was necessary to have a meter that would keep a record of its consumption. At first so many lights were supplied, and so much was charged for them. Various types of meters have been placed on the market, but there are only two or three in general use. One system of supplying current is where the pressure is kept constant, as in incandescent lighting. Another system includes a clock which runs only when the current is being used and stops as soon as the use of the current ceases. The latter was invented by Mr. Brush, and was used chiefly for charging batteries.

One of the best electric meters now in regular commercial use is that known as the "Edison," which has been in use for about ten years. There is also the Ayrton and Perry meter, which is well known and highly efficient.

Prof. Cross then caused to be thrown on a screen pictures of various types of electric meters, including the Thomson, Forbes, Shallenburg and others, a lucid explanation of the principle of construction adopted in each one and the method of their operation being given. There were also exhibited on the platform Edison, Thomson, Shallenburg and other types of meter, which the lecturer called the attention of his audience to, and showed their working by turning on current to first one and then another of them.

PRODUCTION OF ELECTRICITY FOR INDUSTRIAL PURPOSES.

Prof. Cross delivered another lecture in the course at Huntington Hall, Boston, November 9, his topic being "The Production of Electricity for Industrial Purposes; Dynamo-Electric Generators." In beginning this address the lecturer said the modern dynamo considered as a generator of electric current consisted of two kinds of machines, those operated by direct and those operated by alternating currents, the latter making from 50 to 200 reversals per second.

All the modern direct current machines were evolved from the originals of Pacinotti and Gramme, two inventors who lived only a few years apart.

He would speak of the direct current machines first, having already shown that by constantly rotating a hoop of metal in a magnetic field an electric current was produced, and with the use of a properly constructed commutator such current could be collected and utilized. Utilizing the earth's magnetism, it was shown that by taking a metal hoop and rotating it on its axis in line with the plane of the earth's surface, according as the lines of force through which the hoop rotated diminished the current would flow in a direction to the right hand, whereas if the lines of force were increased the current would flow in the opposite direction. When the hoop was in the line of the earth's plane, that is, north and south, the current was at zero, and as the hoop or coil rotated so the current was reversed.

Considering next the magnetic field with a single metallic ring rotating in it, the current was reversed according as the ring changed its face. If a series of whorls or turns of wire were extended round the circle, it would be seen how the current moved and was rapidly changed as it entered and left the different whorls. The electromotive force moving in opposite directions from the two poles neutralized each other, and so lost its potential.

Taking an oblong square iron frame, Prof. Cross said that the result of moving it through the lines of force would be to induce the flow of current upward on both sides of the square frame. If a piece of soft iron were placed in a magnetic field, it would be found that the lines of force passing through it were diverted by the piece of iron, and instead of passing through in straight direction, the lines take a curved course, following the current of the iron ring rather than through the air existing in the interior of the ring. This was discovered by Gramme in his original ring. A diagram was then shown illustrating how a series of wires was run along a ring with their ends joined one to another and connected by brushes resting against a number of copper bars separated from each other by suitable insulating material.

Figures of a Gramme ring, commutators of the Westinghouse type, Thomson-Houston armature winding, core of a drum armature and other parts of dynamo machines were then shown by the aid of a powerful lantern, and described.

Proceeding, Prof. Cross said it had been found absolutely necessary to laminate the armature of dynamos to prevent the occurrence of eddy currents, which formerly were excessively great and were a danger to the machines themselves. The dynamo designed and built by Moses G. Farmer in 1878 was described and approvingly commented upon.

Prof. Cross next proceeded to explain the different parts of a dynamo, and the processes through which it passed in building, reminding his hearers that there were many different types of machine now in regular and satisfactory use, some of them being known as shunt and others as compound wound dynamos. In the latter the current was not so steady as in a shunt wound machine.

In order to secure high efficiency, it was necessary to use coils wound with fine wire, the coils offering a high resistance which was necessary to secure a high electromotive force. For incandescent lighting, what was known as a series machine was used.

Having given in some detail the principles involved in making these different types of dynamos, the lecturer showed a small Gramme machine that would run a single arc light, a Siemens machine with a drum armature, a separately excited machine made in the Massachusetts Institute of Technology, an Eddy shunt wound machine, an Edison current type and an old type Edison machine, a Westinghouse and Thomson-Houston machine, pointing out the salient points and characteristic features of each in succession.

Recollections of Werner Von Siemens.*

II.—Saved to Science by a Timely Discovery.

We soon learnt that as punishment we were all to be sent back to our brigade—or our regiment, as it is now again called. For me this was an almost insupportably hard blow, disturbing all my life-plans, and making it impossible for me to go on providing for my younger brothers. The problem was to find a way to prevent this removal. That was only to be attained by an important military discovery, which should necessitate my presence in Berlin. Telegraphy, in which I was specially interested, could not perform this service, for only few then believed in its great future, and my projects were still undeveloped. By good luck gun-cotton occurred to me, which a little while before had been discovered by Professor Schönbein in Basle, but had not yet been brought into use. It appeared to me indubitable that it could be so improved as to be made available for military purposes. I therefore went immediately to my old teacher Erdmann, professor of chemistry at the Royal Veterinary School, told him of my trouble, and begged permission to institute experiments with gun-cotton in his laboratory. He willingly granted it, and I went eagerly to work.

I had the idea that by employing stronger nitric acid and by more carefully washing and neutralizing a better and less easily decomposable product could be obtained. All the experiments however came to nothing, though I used fuming nitric acid extremely concentrated; a greasy easily destructible product was always the result. My stock of extremely concentrated nitric acid having run short I once tried the effect of adding some concentrated sulphuric acid in order to strengthen it, and to my astonishment got a gun-cotton with altogether different properties. After washing it became white and firm like the unchanged gun-cotton and exploded very energetically. I was overjoyed, made till late in the night a considerable quantity of such gun-cotton and placed it in the drying-stove of the laboratory.

When after a brief sleep I went again early in the morning to the laboratory I found the professor standing mournfully among ruins in the middle of the room. On heating the drying-stove the gun-cotton had exploded and destroyed the stove. A glance made this clear to me and showed the perfect success of my experiments. The professor, with whom I in my joy tried to waltz round the room, seemed at first to think I had gone wrong in the head. It cost me some trouble to set his mind at rest, and to induce him to resume the experiments at once. About eleven o'clock I had packed a goodly quantity of faultless gun-cotton, and sent it with a formal explanatory letter to the war-minister.

The result was glorious. The Minister of War instituted a shooting-trial in his large gardens, and as it went off brilliantly immediately induced the heads of the Ministry to make a regular trial with pistols. On the very same day I received an official order direct from the Minister to repair to the powder manufactory at Spandau, which had already been instructed to place everything requisite at my disposal, to institute experiments on a large scale. It is seldom I fancy that a memorial to the War Office has been so quickly acted upon. Of my returning to the brigade there was no more talk. I was soon the only one of my brothers in misfortune who had not been obliged to leave Berlin.

The experiments on the large scale, which were made under my directions in the powder factory at Spandau, did not lead to the result expected in the first glowing moments, viz., that gun-cotton would generally supersede gunpowder. It is true that trials with small arms as well as with cannon yielded excellent results; it appeared, however, that gun-cotton was not a sufficiently fixed combination, since it gradually decomposed in the dry state, and occasionally also would go off of itself. Moreover its effectiveness depended on the degree of compression of the gun-cotton and on the mode of its ignition. My report therefore ran, that the gun-cotton produced according to my method by means of a mixture of nitric and sulphuric acid possessed excellent properties as a blasting material, and seemed well suited to take the place of blasting powder for military purposes but that it could not in general be substituted for gunpowder, as it presented no sufficiently stable chemical combustion, and its action was not constant enough.

---

* Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

I had already sent in this report when Professor Otto in Brunswick discovered anew and published my method of preparation of serviceable gun-cotton. My earlier action in the matter and my report to the War Office remained of course secret, and Otto therefore must rightly be held the discoverer of serviceable gun-cotton, since he was the first to make public the method of its production. It has often been so with me. It appears at first sight hard and unjust that any one may by earlier publication appropriate the honor of a discovery or invention which another, who has worked at it long with ardor and success, would only make known after the most thorough testing. On the other hand it must however be admitted that some definite rule must be established in regard to priority, since for science and the world it is not the person but the thing itself and its publication that is of importance.

After the danger of removal from Berlin had been in this manner successfully averted I was able to devote myself with a tranquil mind to telegraphy. I sent General Oetzel, the chief of the optical telegraph department under the immediate direction of the staff, a memoir on the condition of telegraphy and the improvement to be expected therein. In consequence of this I was ordered to place myself at the service of the commission of the staff, which was deliberating on the introduction of electrical instead of optical telegraphs. I succeeded in gaining the confidence of the general and his son-in-law, Professor Dove, in so high a degree that the commission almost always assented to my proposals and entrusted me with their execution.

It was then regarded as altogether out of the question that a telegraph wire easy of access, attached to posts, could be really serviceable, since it was imagined the public would destroy it. Accordingly, wherever on the European continent it was desired to introduce electric telegraphs, experiments were first made with subterranean conductors. The best known were those of Professor Jacobi in St. Petersburg; he had tried resin, glass-tubes, and indiarubber as insulators, but had obtained no permanently satisfactory results. The Berlin commission likewise had begun such experiments, which however just as little yielded a satisfactory durable insulation.

By chance my brother William in London had sent me as curiosity a sample of a substance which had recently appeared in the English market, gutta-percha. The remarkable properties of this material of becoming plastic in the heated state, and when cooled of being a good insulator of electricity, aroused my attention. I covered some pieces of wire with the heated material, and found that they were thoroughly insulated. At my suggestion the commission gave orders for more considerable experiments with such wires insulated by gutta-percha, which were begun in the summer of 1846 and continued in 1847. In samples placed on the track of the Anhalt Railway in 1846 the gutta-percha was rolled round the wire. It turned out however that the coil got loosened in course of time. I accordingly constructed a screw-press, by which the heated gutta-percha was cohesively pressed round the copper wire under the application of a high pressure. The conducting wires, coated by the help of a sampler press constructed by Halske, proved to be well insulated and permanently retained their insulation.

In the summer of 1847 the first long subterranean wire from Berlin to Grossbeeren was laid by me with such insulated wires. As it stood the test perfectly the question of the insulation of subterranean wires by the employment of gutta-percha and my press appeared to be now successfully solved. In fact since that time not only the subterranean land lines but also the submarine cable lines almost without exception have been insulated in this manner.

The commission had under consideration the employment both of the wires coated with gutta-percha by pressing and also my dial and printing telegraph, in the telegraph system about to be introduced into Prussia.

The resolution to devote myself entirely to the development of telegraphy was now fixed. Accordingly, in the autumn of 1847 I induced the mechanician J. G. Halske, with whom our common labors had bound me closely, to hand over his business to his partner and to start a telegraph factory, into which I reserved to myself the right of entry on my discharge. As Halske just as little as I had available resources we had recourse to my cousin, George Siemens, a barrister residing in Berlin, who lent us 6,000 thalers for the erection of a small workshop on condition of a share in the profit for six years. The workshop was opened on the 12th of October, 1847, in the back part of a house in the Schöneberger Strasse—where Halske and I also took rooms—and grew rapidly and without the aid of outside capital into the world-known establishment of Siemens & Halske in Berlin, with branches in many of the chief cities of Europe.

The enticing prospect, in virtue of my dominating position in the telegraph commission, of rising to be the head of the future Prussian State telegraphs I had put aside, as a position of dependence was not congenial to me, as I had the conviction I should be of more service to myself and the world if I obtained my full independence. But I resolved not to renounce the military service, and therewith my place on the military commission, before the latter had completely accomplished its task, and a definite settlement of the future telegraph system had been arrived at.

I urged in the commission that the public should also be allowed the use of the telegraph lines, which met with considerable opposition in military circles. The great celerity and certainty with which my new patented dial and printing telegraphs worked on the overhead line between Berlin and Potsdam and on the underground line between Berlin and Grossbeeren—performances with which those of the old semaphores were not to be compared—contributed however in no small degree to produce an opinion more favorable to the public interest. The report of astonishingly favorable results of these experiments went the round of the higher circles in Berlin, and brought me a command from the Princess of Prussia to give a lecture in Potsdam on electric telegraphy to her son, afterwards Crown Prince Frederick William and Emperor Frederick. This lecture, accompanied by experiments on the Berlin-Potsdam line, and a memoir connected therewith, in which I enlarged upon the great future in store for telegraphy, supposing it to be made the common property of the people, no doubt considerably assisted in gaining over the higher circles.

At my instigation the commission instituted a public competition for March, 1848, and settled the conditions to be satisfied in regard to the telegraphic communications and apparatus. Prizes were assigned to the conquerors, who were also to have the reversion of consequent orders. I had a pretty safe expectation of obtaining the victory with my own proposals at this competition, which opened on the 15th of March, 1848, when on the 18th the competition as well as the commission itself came to an abrupt end.

(*To be continued.*)

Legal Notes.

In the Circuit Court at Eau Claire, Wis., on the 16th inst., Judge Bailey confirmed the sale of the National Electric plant by Receiver Rust to Peter Truax for $7,500. The attorney for the receiver asked the court for an order restraining the Chicago creditors who filed their claims at Eau Claire under the receivership from going on with suits instituted in Chicago against the National Electric. Arguments on this motion are to be heard December 11.

The receiver of the Electric Power Company of Philadelphia has presented an audit of the company's accounts which will give the creditors about 5½ per cent. of their claims, there being $2,001.09 with which to pay $36,383.58. The Electric Power Company was originally a New Jersey corporation, but secured a charter in Pennsylvania on November 29, 1889, and had a contract for lighting a section of the city of Philadelphia. Mr. Wray was appointed receiver on March 30, 1891, under a bill in equity filed by George V. Cresson, who alleged that besides judgments held by him there were other claims against the company, and that it was unable to meet its obligations. Among the largest creditors were the Fort Wayne Electric Company, $7,586.97; Electric Dynamic Company, $3,086.06; Bank of the Metropolis, $7,458; estate of Elizabeth Maitland, $8,000; Joseph Ogden, $2,500; William Thornton, $563, and about twenty-five others in different amounts.

A verdict was rendered at Pittsburg, Pa., on the 21st inst., in the United States Circuit Court case of the Edison General Electric Company vs. the Connellsville, New Haven and Leisenring Street Railway Company for $12,023 in favor of the plaintiff. It was an action to recover for machinery sold.

In the Common Pleas Court at Cleveland, Ohio, on the 20th, Amos Townsend and Wm. M. Brown filed a petition asking for an accounting, injunction and equitable relief against the Euclid Avenue National Bank and the General Electric Company, Boston. The plaintiffs are joined as Townsend & Brown, owners of a street railroad at Montgomery, Ala. The bank holds their note for $6,000, with certain collateral security which was given to the General Electric Company as part payment for certain electrical apparatus supplied Townsend & Brown. They claim the apparatus is inferior to the specifications and they object to paying the full sum agreed upon. For this reason they ask for an accounting. The injunction prayed for is to prevent the note and collateral being taken outside the State to be negotiated. They claim the bank demands usurious interest on the note, and this they refuse to pay.

The Pennsylvania General Electrical Company of Philadelphia has brought suit against the Carbondale Traction Company to recover $8,000. It is alleged by the plaintiff that the amount is due by the Carbondale Company for equipment furnished.

New York Electrical Society.

On Wednesday, the 29th inst.. the New York Electrical Society will hold a symposium at Columbia College, Forty-ninth street and Madison avenue, at 8 P. M. The subject of the evening will be "Electricity at the World's Fair and its Lessons."

Brief addresses will be given by J. J. Carty, on Telephones; Prof. F. B Crocker, on Electrical Congresses; Charles Cuttriss, on Cables; Dr. C. E. Emery, on Electric Light Engines; James Hamblet, on Electric Clocks; C. O. Mailloux, on Storage Batteries; T. C. Martin, on Electric Lighting; Nicola Tesla, on his new Electrical Oscillator; Jos. Wetzler, on Transportation; and Schuyler S. Wheeler, on Electric Motors.

National Electric Light Association.

At a meeting of the Executive Committee of this Association, held at the Lafayette Hotel, Philadelphia, November 24, it was unanimously voted that the next meeting place of the Association should be Washington, D. C. The date of meeting will be February 27, 28, March 1, 1894.

The following committees were appointed:

Committee on Arrangements: C. O. Baker, Jr., Chairman; F. W. Royce, Washington, D. C.; Samuel M. Bryan, Washington, D. C.; M. J. Francisco, Rutland, Vt. Committee on Programme: A. J. De Camp, Chairman; C. W. Price, New York; H. H. Fairbanks, Worcester, Mass.

A Check on Contract Customers.

An invention known as the Martin check apparatus has been designed in France for limiting the current which can be used by customers supplied on a contract basis to the maximum amount called for in their contracts.

The following description of this device is given in the *Foreign Abstracts* of the Institution of Civil Engineers: "It is very usual in France for an electric lighting company to furnish current by contract to consumers, and in such cases a consumer may have any number of lamps installed so long as he never has more than a certain fixed number lighted at once. It is therefore necessary to use some apparatus for the purpose of preventing fraud and making it impossible to use more than the stipulated number of lamps at one time. As a rule, this object is accomplished by using switches with two or more different contacts, so that when the current is shut off from one circuit it is admitted to others. This method, however, complicates the internal wiring, and the grouping of the lamps easily permits of fraud. On the other hand, the reliability of cutouts is very doubtful. The Martin apparatus is designed to prevent the use of more than the stipulated number of lamps, while permitting absolute freedom in the grouping or wiring of such lamps. Such an apparatus is also of use in a private installation, to prevent overloading of the generating plant. The apparatus is placed in one of the main leads, and consists of two mercury-cups provided with a metal contact-maker attached to the end of a lever, and provided with a spring to cause a quick break in the mercury-cups. The lever is commanded by one or other of six pins standing at right angles to the flat face of a wheel, which is stationary when the stipulated current is not exceeded, and holds the contact in the mercury-cups. Clockwork is so arranged as to always tend to rotate the pin-wheel, and if this motion were not controlled, the circuit would be made and broken at short intervals by the contact-piece in the mercury-cups. One of the train wheels is, however, provided with a single pin, which is held by a projection on a spring lever during the whole time that the current in the circuit does not exceed the quantity stipulated. The spring lever carries at its free end the armature of an electromagnet, which is placed in the main circuit, and the strength of the spring upon the lever is so adjusted that, so soon as the maximum stipulated current is exceeded, the armature is attracted and the train of wheels set free. Contact is then made and broken at short intervals of time, and the customer is obliged to take one or more lamps off the circuit, thus bringing the current down to the normal when the train of wheels is stopped and the permanent contact is again made. In actual practice a clock movement of the Japy type is employed, but only the five wheels of the striking mechanism are preserved, with the detent spindle and its lever, and the spindle of the hammer. The hammer shaft is retained, but the head is replaced by a piece of hard rubber, carrying a copper fork dipping into the two mercury-cups. The author gives some further details of the method of manufacturing this particular type of clock. He states that the act of switching in a 5 C. P. lamp on a circuit of 110 volts is sufficient to actuate the apparatus—supposing, of course, that such a lamp be in excess of the stipulated number of lamps which are already lighted. The loss of pressure upon the circuit is said never to exceed 0·2 volt. The whole is covered with a glazed lid, and can be sealed up. A counterpoise is so arranged that it is impossible for a consumer to keep too many lamps lighted until the clock has run down, in which case the circuit would become permanently closed; the counterweight causes the circuit to remain permanently open until the number of lamps in use is reduced to the stipulated maximum. This instrument has, it is stated, given satisfaction in one of the eastern towns, and a servant of the company calls once a month upon each customer for the purpose of winding up the apparatus. Such a clock-movement would run for fifteen days and give 2,700 interruptions, and it is found that the spring is very seldom run down in a month."

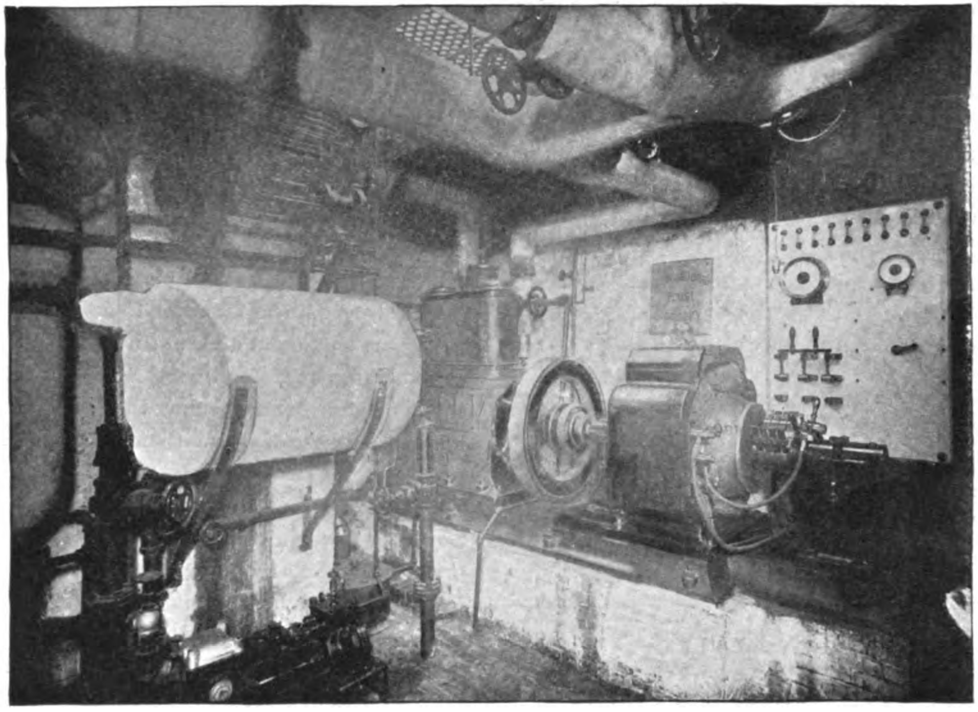
A Model Installation.

The drift to-day in the field of electric lighting is in the direction of slow speed machines, and of late some striking and highly satisfactory results have been attained in this new departure. Combined with the saving effected in wear and tear as the outcome of reduced speed in the running of dynamos and generators is another important factor, the economizing of space actually required for the installation of a steam and electric plant.

Direct coupled engines and dynamos have largely solved the problem bearing on the advantages of electric lighting on shipboard and in buildings where space for such apparatus is not always available even to a limited extent. Many a man eager to equip his building with electric machinery has had to abandon the idea because he couldn't afford the space a plant would call for. Such policy is now a thing of the past. The objection has been fully overcome, and this article gives a description of a unique installation of this kind, where the space at command was very limited, but which was so utilized that quite a plant has been installed and is doing extensive and most efficient work.

The International Trust Company of Boston, one of the leading banks in that city, has recently erected a magnificent stone building of nine stories close by the Post Office. This handsome block has just been finished, and is open for business. To light the whole building a 500-light plant was necessary, and to accommodate such a plant a very limited floor space in the basement was available. The Mather Electric Company, of Boston and Manchester, Conn., was intrusted with the contract, and with such limited space as could be afforded it was decided to install what is known as the "Kodak" type.

The accompanying cut gives a good view of this plant, in the running of which neither belts, shafting or pulleys are required. The plant consists of one 30 kilowatt or 500-light Standard Multipolar Mather Dynamo, which makes 350 revolutions per minute, the armature shaft being coupled direct to a 9½" x 9" Westinghouse engine. Unusual as it may seem, engine and dynamo are both mounted upon one bed plate and occupy a space of only 86½" x 35", whereas the ordinary method of belting a dynamo to an engine would require nearly three times that space. A handsome marble switchboard having every modern improvement is fixed on the wall near by so that the engineer in charge has everything at hand.



Dynamo Room, International Trust Company's Building, Boston.

This, we believe, is the first plant of this type that has been installed in New England, but it is giving such full satisfaction, is so unique in design and compact in installation, and is evoking so much favorable comment from all who have seen it, that inquiries are frequent and the manufacturers are looking forward with great confidence to doing quite an extensive business with the "Kodak" type of electric lighting plant.

Current for 500 lights generated in a space, as we have above stated, of only 86½" x 35" is something so unique that the system cannot fail to become popular.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

Electric Power on Canals.

The experiments in electric propulsion for canal boats which were recently undertaken on the Erie Canal near Rochester call to mind the importance of this method of transportation, which it is safe to say is not generally appreciated at its true value. New York's supremacy as a seaport is largely due to this waterway connecting it with the great lakes, and in order to maintain this position it is essential to provide for the constantly increasing freight traffic in Western produce which has already begun to seek outlets through other channels, thus diverting from the State a large amount of commerce which proper facilities would secure to it.

Governor Flower, who has strongly advocated some method of improvement in the facilities of the Erie Canal, said in a recent speech: "What a great stride this Empire State took when the Erie Canal was built! It wasn't the canal it is now, either. It was four feet deep instead of six feet and a half. But it brought this State to the front. Massachusetts and Pennsylvania were both in the lead of New York up to that time. But as soon as the waterway tapped the commerce of the great West, cities and villages sprang up all along the line. These cities and villages didn't spring up along the line of the Central-Hudson Railway, but along the line of the Erie."

It is also significant that the Canadian Government is reaching out after much of this Western grain traffic and improving the facilities for transportation by deepening the St. Lawrence channel and the Welland Canal at a very large expense.

The average speed attained by canal boats is now about two miles an hour, and the canal will probably admit of its being increased to four or five miles. The doubling of the rate of speed would mean that each boat could make twice as many trips during a season, double its earnings and increase the total annual tonnage of the canal very largely without further deepening of the channel.

It is estimated that with power from the Niagara station the expense of bringing a bushel of grain from the wheat fields to New York would only be in the neighborhood of five cents, and at that price, with the enormous carrying capacity of the large canal boats, the shipping of grain from New York would be more than quadrupled, with a corresponding increase in the carrying trade of the State.

The experiments near Rochester indicate that electric propulsion is feasible, although the conditions of the test were not perfectly satisfactory. The steam canal boat used was equipped with two twenty-five horse power street railway motors arranged for a pressure of 500 volts, and current was supplied from a neighboring electric railway, but this was, according to the readings on the test, only at from 200 to 500 volts, which was an unfavorable condition for the machinery.

Notwithstanding this circumstance the boat attained a speed of nearly four miles an hour, and no difficulty was experienced with the underrunning street-car trollies either in passing the lock or rounding the curves. Before the start, however, some trouble was found in placing the boat in position under the trolley line, and this suggests the use of overrunning trollies in order to give the boats more freedom of position.

As a whole the test may be considered as a success as it demonstrated very clearly the possibility of this style of propulsion. The details of the apparatus were crude and the supply of current insufficient, so there is little room to doubt that with the apparatus and current which would be used in the practical application of electricity on boats the greatest speed which the canal would allow could be easily attained.

……o……

American Practice Criticised.

Our London contemporary, *The Electrician*, seems to resent the idea that England can learn anything from American electrical engineering practice except what is to be strictly avoided, and paints a most unflattering picture of nearly everything electrical in this country. The New York and Chicago telephone line is thus depreciated: "We venture to suggest that, electrically, the London-Paris, or the Glasgow-Belfast telephone cables are each a 'bigger thing,' except in mere pounds of copper and hundreds of miles, than the New York and Chicago line."

The electric railways come in for the most severe criticism of all, and the Chicago-St. Louis scheme, in which no one but its promoters have any faith, is held up as a terrible example. The horrors of our street electric railways are described as vividly as even the New York daily papers could desire. Other examples of our engineering practice are noticed as follows: "A fortnight ago a shocking accident occurred at Oregon, when a tramcar with thirty passengers dashed through an open drawbridge into the river, killing, it appears, twenty-five people. Last month a flywheel burst at Brooklyn, wrecking the engine-house, stopping all the cars in the city driven from this station, and injuring three persons. Two days later the whole of the street lighting plant of Baltimore was destroyed by fire, together with plant for running 12,000 glow lamps."

It also charitably hopes that in the Niagara power plant no gigantic breakdown of the huge alternators will compete for magnificence with the Falls themselves. From the tone of our contemporary we infer that accidents in any class of engineering work are totally unknown in England, for which it is to be congratulated, and while the plea for better construction and more substantial work is to be commended, the examples mentioned above are hardly fair illustrations of all the electrical engineering work in this country. We certainly have a large proportion of plants of various kinds which are creditable specimens of engineering work, and the comparison of percentage of accidents to the total amount of work installed in both countries might look more favorable to American engineering practice. As the English practice in electrical work has generally waited for the benefit of American experience, we naturally look for some improvement over the older work.

Personalities were Justified. There has been some criticism of Electricity's conduct of its protracted campaign against the General Electric Company by men who believed an attack justifiable, but whose sensitive souls shrank from the idea of doing anything more than condemning its policy on broad generalities. We have frequently labored with these critics privately, and have almost invariably convinced them that they were wrong and that Electricity was wholly right.

But in the progress of events the truth is coming out, and it is generally becoming evident to even the most obtuse observer that personalities were fully justified—nay more, demanded—if Electricity was to have any marked force in forming public opinion; and that is what we have endeavored to do, to enlighten the public as to just what the sham Trust was, what its success in selling stock meant in frightening capital away from electrical investments, and what its success in the trade would mean to honest competitors and to the public. We believed that the make-up of the company was disreputable, and honest men were handicapped in competition for business. We have therefore labored to spread the truth. That we have fully succeeded in our undertaking any one who mixes much with his fellow-men can easily prove by observation. The name of the company is despised and derided in the money centres and in the trade, and their business has utterly dissolved. They are totally wrecked, and in a worse condition than if legally declared bankrupt.

It is proper to inquire why this is so, and the only answer is found in the fact that the unloading of the stock on the public was little better than a swindle, and that the entire business machinery of the company has been honeycombed with corruption and rascality.

Honest men cannot engage permanently in a dishonest business, and dishonest and corrupt men must not be looked to to carry on a legitimate business. It was therefore the duty of Electricity to point out, not alone that the business methods of the General Electric Company were corrupt, but that men occupying the highest positions were corrupt, and must be cleaned out of the management before better things could be expected.

Garfield, the absconding Controller of the city of Detroit; McDonald, the wrecker of the Madison Square Bank; Sunny, accused of being a party to a $200,000 steal and discharging the man who discovered it, and Coffin, the bosom friend and confidante of all three, are object lessons which cannot be argued away.

The General Electric Company has failed because it deserved to fail, and because decency was not in it.

……

It is a good legal opinion that the entire Board of Directors of the General Electric Company could be indicted, tried, and convicted under the New York State statute which makes it a felony for any corporation to pay dividends which have not been earned and the payment of which impairs the capital stock.

……

It seems that Mr. Coffin has been told that his libel suit against Electricity was very heavily loaded. A few of us suspected as much six months ago, but we wonder where Fidus Achates found it out.

……

Electricity has made few prophecies, and those we have made have been fulfilled. We feel safe at this time in expressing the opinion that the merchandise creditors of the General Electric Company have no cause for anxiety. These bills cannot fail to be paid in full. A receivership, furthermore, seems very improbable, and if there is one it will be brought about by the undecided fight between Mr. Coffin and the respectable portion of the management. If there is any change in this situation, we shall be perfectly free in printing the news. The probable solution of the present difficulty is a reorganization, and a surrender by the common stockholders of 50 per cent. of their holdings.

……

The Sham Trust loses whatever of sympathy might be aroused by its pitiable plight by scratching and biting like a dying dog. The lessons of the long campaign of lamp litigation seem to have been utterly lost upon those brilliant intellects who thought the entire electrical trade could be bottled up. The decision in the Oconto case can scarcely be looked for now before January and the application for an injunction against the Novak people may not be decided so soon as that. Meantime we are in position to assure our readers that *the question of the time of expiration of the Edison patent will be rushed to an early decision.*

……

The Grand Jury has found indictments against nine men concerned in the wrecking of the Madison Square Bank. Among them, deeply implicated according to the findings, is Mr. R. T. McDonald, a gentleman who is not unknown to the readers of Electricity.

General Electric.

(*From the Boston Herald.*)

"Holland," the versatile writer of the Philadelphia *Press*, tells a General Electric story which many people will like to read. He says General Electric's peril last summer was probably greater than any of the other industrials, and the rich men who were associated with it made greater losses than in any other business investment. Mr. Morgan, D. O. Mills and F. L. Ames were enthusiastic about the property. Then came the fall in the stock, and the many stories to account for the great decline, but it has always been a mystery. The rivalries of the New York and Boston capitalists were never confirmed. The drop came in spite of Mr. Morgan's efforts, and he seems to have raised the white flag of surrender. He went into his own pocket to protect those who relied upon his name and invested in this property. The loss of capitalists must aggregate $10,000,000. One says he lost $2,000,000, another says $1,000,000, and Mr. Ames probably lost $3,000,000. A combination was made last spring to support the stock around 70, and here comes in one of the most confidential and dramatic of Wall Street stories. One day when the Street seemed combined against the stock the pool sent to Mr. D. O. Mills that it must have at least a quarter of a million dollars instantly if the stock was to be protected, and he must furnish it. Mr. Mills replied "But I can't furnish it, and therefore I shan't." A messenger was sent back to tell Mr. Mills that if he did not furnish this money he would be frozen out. Mr. Mills sent back word that he could not get the money without making a fearful sacrifice, and therefore he could not furnish it. It was suggested to go to Mr. Sage, but his unfriendly eye for Mr. Morgan prevented, and so that day witnessed the greatest fall in General Electric stock. Mr. Morgan about that time formed a new resolution, which is said to have been made by him with great emphasis: "Henceforth I shall never spend a dollar to maintain the price of a security upon the exchange, or to put the price to any figure. I have done with that forever. I shall attend to banking business and shall stand under no security." Soon after this a great block of General Electric was dumped on the market, and it would be very hard to find a capitalist who is not persuaded that this stock was Mr. Morgan's. Holland thinks Mr. Ames was killed by the fall in General Electric. He had 40,000 shares which cost more than 90, and below 40 Mr. Ames began to buy heavily, but his anxiety over the matter was greater than he could bear, and he died.

(*From the Boston Bulletin.*)

GENERAL ELECTRIC.

General Electric has been an especially weak sister during the last few days and has declined amid all sorts of rumors. This column was the first to expose the actual weakness of the company by a thorough analysis of its first annual report. The stock was then 105 and the press and everybody was bullish on it. Our original claims have since been justified, and there is no longer any reason or need to criticise the company's affairs. Nearly every one understands that its business has been scattered and has escaped through other channels, and that it has had continuous difficulty with maturing paper of sub-companies which it endorsed. That the Fort Wayne Company has already severed its connections with the General Electric, and that others are likely to do so at the January meeting.

The Street also has a fixed idea that this January meeting will produce other important results. It is thought that a plan of reorganization will be discussed which will include the scaling down of the capitalization. The payments of the preferred dividend in January is questioned and the sales of the stock this week "seller 60" have doubtless some significance. The General Electric knows now it made some grave mistakes, both as to the financial and business management of the company. Let it then gather itself together and begin afresh, trying to do less business, but more for cash than in the past.

Why They Will Give Thanks.

Various People for Various Causes, as Reported by our Divinator.

Charles Schieren—Because at least 100 of the 900,000 people in Brooklyn want no offices.

Edwin J. Houston—Because he sold his General Electric at 115.

S. Dana Greene—Because he does not know any less than he did a year ago.

C. H. Coster—Because all of Drexel, Morgan & Company's money is not in General Electric.

Henry Hine—Because Pittsfield is so near New York.

W. J. Johnston—Because the advertising public is so easily humbugged.

W. A. Kriedler—Because he is not eating turkey alone this year.

J. H. Rhotehamel—Because Trusts are not in it in Missouri.

C. A. Coffin—Because Ravvy was found out first.

R. T. McDonald—Because John R. Fellows, and not De Lancey Nicoll, will try his case.

E. I. Garfield—Because Electricity did not publish his record.

Robert Corey—Because he is no fatter than he is.

Charles D. Shain—Because he is not quite so fat as Bob Corey.

A. H. Reece—Because he is not half as fat as Shain.

T. C. Martin—Because Brother Johnston's guns were only loaded with mud.

Nelson W. Perry—Because he resigned the editorship of the *Electrical World* and once again has a clear conscience.

Paul T. Brady—Because he is no longer compelled to earn his daily bread by digging postholes in Cooperstown.

B. E. Sunny—Because his superiors are tarred with the same stick.

Many Others—The same.

H. M. Byllesby—Because he has got Sunny's job.

Pennock—Because there is a sucker born every hour.

Wellington Adams—The same.

Eugene Griffen—Because he can re-enter the army when General Electric busts.

Samuel Insull—Because there are no flies on the Chicago licensee company.

W. S. Barstow—Because he will soon be superintendent of the finest central station in America.

C. O. Baker—Because he has never known any reason for doing otherwise.

T. Carpenter Smith—Because he can say, like the late Governor of Wisconsin, "I seen my duty and I done it."

Lemuel Bannister—Because the Westinghouse Company has landed the choicest contracts of the year.

James Godfrey—Because the feeder patent can be knocked into smithereens.

Thomas A. Edison—Because the American patent system, notwithstanding its faults, made him a rich man.

Elihu Thomson—Because he was never in sympathy with the policy of extermination.

D. P. Perry—Because he kept out of all combinations.

Sigmund Bergmann—Because he got out at the proper time.

Edward H. Johnson—Because if the next president of the General Electric Company could be elected by popular vote he would be the winner.

A. D. Newton—Because the Eddy Company is working full time.

Sam Booker—Because he has been reconstructed.

James A. Roberts—Because the Democrats knew how to vote better than he gave them credit for.

John Muir—Because he made hay when the sun shone.

H. J. Smith—Because Nelson's is in easy walking distance from Pearl and Elm streets.

E. E. Bartlett—Because the electrical trade appreciates high art.

The Electrical Corporation—Because their millions of worthless bonds are at least unassessable.

Frank Sprague—Because he can survey the Edison wreck with perfect composure.

The Ames Heirs—Because they have escaped from Mr. Coffin's clutches.

H. S. Kaliske—Because all his eggs are not in one basket.

Dan Spruance—Because he is not compelled to spend all his time in Philadelphia.

E. J. Spencer—Because he is not as other men are.

Alex. Lewis—Because he is now working for an honorable concern.

John Seeley—Because he has boundless faith in the future.

Charles Huntley—Because his company is making money.

James Ayer—Because some other town will have to entertain the gang this year.

Eugene Phillips—Because the boys are all fond of clams.

John I. Beggs—Because he didn't lose all that he had.

O. T. Crosby—Because he gets credit for other men's work.

Siemens & Halske—Because they declined Mr. Coffin's million-and-a-half bonus.

Charles G. Curtis—Because even his competitors admit that he has got a good thing.

Parry Browning—Because it is a long lane that has no turn.

The Canal Mule—Because he has lost his job.

The Canal Boatman—Because the trolley is less dangerous than the hind legs of the mule.

Chicago Men—Because they don't live in New York.

New York Men—Because they don't live in Chicago.

Everybody—Because Electricity is published fifty-two times a year.

Electricity—Because it is better to be right than to be affluent.

CORRESPONDENCE.

To the Editor of Electricity.

Dear Sir: The article in Electricity of the date of November 22, in regard to the Ansonia Electric Company's affairs, was evidently written under a misapprehension, or in ignorance of the facts, and is therefore so apt to work an injury to the company's creditors and an injustice to the previous management of the company that it seems to the writer proper that you should be in possession of the actual facts of the case.

When through shrinkage of assets, losses by failures, and inability to make collections, owing to the general financial troubles and to the failure of the company from whom it purchased most largely its material, and with whom it had an established credit for same, and who were large holders of its notes, given in payment of such material, the Ansonia Electric Company was unable to meet its obligations it put its property under the protection of the courts, without a single attachment or preference of any kind, for the benefit of all its creditors alike.

The proposition referred to was made after a careful analysis of the character, condition and availability of the assets, and consultation with a number of the larger creditors and with their approval; and it involves the creditors' abating 40 per cent. of their claims to enable the company to continue business, and thereby realize for them, free of expense, 60 per cent. of same in cash. The whole amount is secured by assets held for them in trust, and unless same is paid in full in eighteen months the claims remain in full force, and it is thought the payments can be completed in much less time.

No one who has carefully investigated this matter questions, and it is a fact, that much more can be realized, and more quickly, by this plan than by liquidation of the company, with the sacrifices that would necessarily follow; and it is submitted to the creditors simply as a business proposition, whereby the greatest amount possible will be realized by the creditors, and an old-established trade saved to the stockholders.

It rests entirely with the creditors whether this plan be carried out or liquidation be enforced, and must be promptly decided. This proposition has already the approval of nearly all of the large creditors and a majority of the smaller ones, and in case it is carried through, the management of the company will be in the hands of a board of directors composed of men of the highest standing in business circles, and will include representatives of creditors. In view of these facts, the article referred to seems unwarranted, and, as before stated, evidently written under a misapprehension of the facts, and whatever action the creditors or any of them determine shall be taken, we wish them to understand now, what in case of liquidation they will surely realize, that we have in good faith presented a proposition involving the least possible loss to them through our misfortune.

The writer will in any case continue in the business, and has given his whole time since the failure to the creditors' interests; and even should they decide to liquidate the business, will assist wherever he is able in realizing the largest possible amount for them out of the assets.

Your truly,

November 25, 1893. J. B. Wallace.

Current Items.

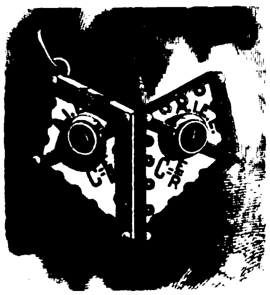
An apparatus which might apparently be of use in the arid sections of the West, which depend upon irrigation to render the land productive, is described in the Proceedings of the Institution of Civil Engineers of Great Britain as having been devised by Mr. Diendenne. It serves to indicate the water level in a reservoir, boiler, etc., at any distance by means of electric signals conveyed by a telegraph wire. The float is connected by a cord to the edge of a circular sector free to turn on its centre, and the pull of the cord is counteracted by that of a dead weight, so that the angular motion of the sector always corresponds to the rise or fall of the float. The sector is of metal, and passes over, in its rotation, a number of metallic arms equally spaced. The electric current reaches these arms through the sector, so that in various positions of the sector different numbers of the arms are in the circuit. Another part of the transmitting apparatus is a semi-circle of ebonite, on which are a number of metal plates, each of which is separately connected by wire with one of the arms above spoken of. On this ebonite plate is a radial arm, which, when it revolves, successively touches each of the metal plates. At the receiving station, when it is desired to know the water level, all that is necessary is to complete the circuit by pressing a button. Suitable electro-magnetic apparatus then causes the radial arm to travel over the ebonite plate, and in doing so the circuit is made and broken for a number of times, which indicates the position of the sector, and so of the float. A telephone is used to count the number of breaks in the circuit, and any degree of precision may be obtained by choosing the number of radial arms to correspond with any desired scale.

The Harrisburg (Pa.) *Independent* says: "It is the mission of the city electric railroads to build up all outlying villages in the near and distant suburbs of such centres of population precisely as it has been the work of the monster trunk lines of steam railroads to increase prosperity and population of cities through and along which they run. Any one who has carefully studied the progress in the improvement of Harrisburg has not failed to notice the steady system under which it has grown in population, real estate improvement and manufacturing and mercantile prosperity. Even the sudden appearance of a crisis in financial stringency could only temporarily check this prosperity, from which retarding influence the entire country is being also rapidly delivered. Our outlying villages and boroughs, now linked to Harrisburg by electric motor railroads, will have their first winter's experience this and next year, in being so closely connected with a centre of large population, in the advantage of which they all profit."

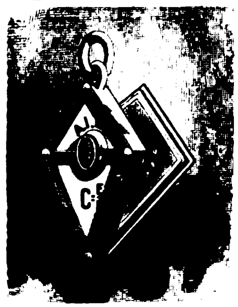
The San Francisco and San Mateo Railroad Company has met the necessity of relieving funeral parties of the tedious and fatiguing journey to distant cemeteries on hackney coaches by adding to its plant cars becomingly furnished for such service. A car lately put on the road for this purpose is not unlike a diminutive specimen of the regular passenger car of the steam railroads, the only marked difference being the long plate-glass windows of the mortuary chamber. It is a dark olive green, trimmed with gold, and the name "Cypress Lawn" appears upon the sides. The interior is fitted up in black walnut, with dark olive upholstery. The ceiling is done in blue and silver. The car is divided into two compartments. In one is the truck for the casket, with appliances for instantly bolting it to the floor, and in the other, separated from the casket chamber by a ground-glass door, seats for the mourners. It seats twenty-four persons in the passenger compartment, with room for twelve or fourteen more in the seats in the chamber with the casket. The car is pulled by an electric locomotive.

The A. I. E. E. Badge.

The Committee upon Badge and Certificate of the American Institute of Electrical Engineers has completed its labors, which have resulted in the adoption by the Institute of a standard pin or badge, that has already been described in these columns, and to meet with demands of certain of the members the badge has been made up in a number of different forms, illustrations of which we present herewith. These can be secured upon application to the secretary, Ralph W. Pope, 12 West 31st street, New York.

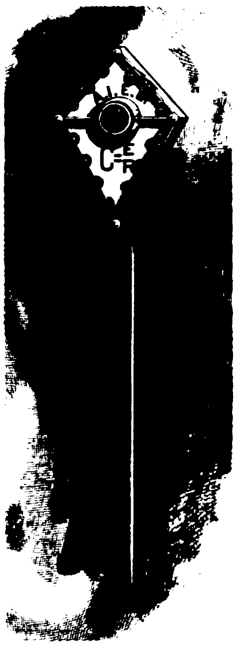


DOUBLE LOCKET.



DOUBLE LOCKET.

The exposed portions of these articles are made of 18 karat gold with a backing of 14 karat gold, and are of the same general character as the badge, of which several hundred have already been issued to members. The prices of the pin, lapel button, scarf-pin and watch-charm are alike, namely, $3; that of the single locket $8, and of the double locket $10.

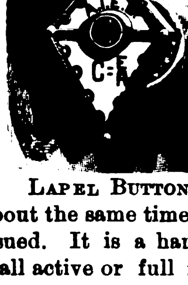


PIN.

SINGLE LOCKET.

WATCH CHARM.

The certificate of the Institute, which was adopted at about the same time as the badge, is now being issued. It is a handsome steel engraving, and all active or full members are entitled to receive it upon application to the secretary and upon the payment of $2 to cover cost of printing and engraving.



LAPEL BUTTON.

The Westinghouse engine which operated the electric dynamos at the World's Fair made 35,806,500 revolutions from the opening of the Fair up to October 30 without stopping. It turned five times every second and ran eighty-three days, two hours and fifteen minutes without a break.

Boston Notes.

The New England Street Railway Company, which owns and operates an extensive system of electric street railways, is to pay its regular quarterly dividend of 14 per cent. notwithstanding the extraordinary depression that has prevailed so long throughout the territory covered by the company.

This year the American Bell Telephone Company paid to the State of Massachusetts a tax of $147,432. This money, assessed by the tax commissioner and collected by the treasurer, is distributed among the towns and cities where the stockholders reside. About 80 per cent. of the stock is held by citizens of Massachusetts, so four-fifths of the tax is distributed in this way, and the tax on the other 20 per cent. swells the revenue of the State. This State tax of $147,432 indicates a valuation of $9,908,300 after a deduction of the market value of the shares of foreign corporations held by the American Bell Telephone Company May 1, 1892, and must indicate an asserted market valuation for these Bell telephone treasury stocks of $22,561,200. If these stocks were held by any other persons, natural or artificial, residing in the commonwealth, they would have been subject to taxation, and if discovered by the assessors might have yielded, at the average rate, $335,710.

We note with pleasure the gradual improvement that is taking place throughout New England in the electrical business. Accounts are being more promptly paid, orders continue to come in freely and everybody is growing increasingly happy. This statement, however, as a fact, does not apply to the General Electric Company, the disintegrating process having become quite chronic, and everybody identified with the Trust is agog as to what is going to happen next. The heads of departments, of whom there are very few now left, make no secret of the chaotic condition into which everything has drifted, and as the process of thinning out the ranks goes on apace, the inquiry goes round—"Whose turn is it next to go?"

Phillipsdale is the practical title by which in future the new factory of the American Electrical Works, Providence, will be known. It needs scarcely to be stated that the above name has been adopted as a compliment to Mr. Eugene Phillips, the genial and universally esteemed president of this prosperous company, whose guests the electrical fraternity have been year after year at the annual clambake on the beautiful Providence River.

The movement in favor of an electric road at Winthrop, Mass., is still agoing, and lively times are being experienced in that popular seaside resort. The younger citizens of the place, appreciating the advantages accruing from better transportation facilities, are very anxious to get a road put in before next summer, while the old residents, those who prefer to maintain things just as they were in grandfather's day, are up in arms against the suggested modern innovation, and so the fight is an interesting one.

There are at the present time in process of construction in Boston some of the largest and handsomest switchboards for theatre and central station work that have ever been built since electric lighting and power became a business. Boston is rapidly becoming one of the most important electrical manufacturing centres in the country.

The rubber insulated shield for application to the brake and motor handles on electric cars as a protection against shocks to the motormen has become a popular success. ELECTRICITY had the pleasure of introducing them to the railway fraternity for Mr. J. J. Lewis, inventor, Boston, and they have been adopted everywhere.

It has just been asserted by a local financier that the shrinkage in General Electric stock during the past few months has reduced the fortunes of Boston and New York parties who hold that stock by more than $10,000,000, and the shrinkage still continues.

A somewhat serious fire] occurred on Wednesday night in Eliot street, Boston, just at a point where is a very thick network of overhead electric wires. While the firemen were handling one of the aerial ladders it came in contact with the wires and became strongly charged with current, with the result that several of the firemen received severe shocks and had to be removed in a semi-unconscious condition. This experience has stirred up the fire underwriters and fire commissioners to the point where they are demanding that all wires shall be placed underground. A lively fight is anticipated.

General News.

What is Going on in the Electrical World.

Seattle, Wash.—The Union Electric Company, which has a 10,000 incandescent lamp lighting capacity, has added a 2,000 light machine to its plant.

Minneapolis, Minn.—A movement is begun here for the annulment of the lighting contract of the Brush Electric Company, and in favor of installing a municipal plant.

Utica, N. Y.—The Utica Electric Light Company has been awarded the contract for lighting the city for three years from January 1, at which time its present contract expires.

Halifax, N. S.—An electric road is needed here, and the newspapers are urging its construction, using the success of the electric street railway in Yarmouth as an argument.

Baltimore.—Some of the city papers are advocating the adoption of a municipal lighting system, and contend that the present lighting companies fail to give the city proper light.

Canonsburg, Pa.—The Electric Light, Heat and Power Company have about concluded contracts for boilers, engines and electric appliances, and will proceed at once to the erection of a power house.

Ottawa, Ill.—There is a growing opinion here that an electric road is needed between Ottawa and Marseilles, and will certainly be built unless the Rock Island Railway officials give Marseilles better service.

Newark, N. J.—A committee of the Board of Trade has recommended an electrical conduit system for Broad street, the principal business street of the city. Among those who favored its adoption was Prof. Edward Weston.

Holland, Mich.—The $12,000 electric light bonds have been taken by outside capitalists, and now the Detroit Electric Light Company will commence immediately to put in the city plant, both for street and commercial lighting.

Trenton, N. J.—Engineers representing the electric railroad syndicate were in Trenton last week overlooking the proposed route lying within the city limits for the road between Newark and Trenton. Surveys will be made in the spring.

Chillicothe, Ohio.—The affairs of the Chillicothe Electric Railway have got into a muddle, and the courts are now engaged in righting matters. The indebtedness of the road amounts to $110,000 in round numbers, and a sale of the road would not, it is said, realize that sum.

Montreal, Can.—The Street Railway Company laid over forty-five miles of track during the past summer, and the Park and Island Railway Company laid about eight miles of track to Back River in the latter part of the season. Both companies are using electrically propelled cars.

Yonkers, N. Y.—The dispute between the city and the electric road having been settled, the company intend to materially improve the service of the road. New cars will be put on, the capacity of the power house will be increased and the running time shortened. New lines are also contemplated.

Springfield, Mass.—The United Electric Company intend building a line from Winchester Park to Indian Orchard, for the purpose of conveying to this city a portion of the electric power produced at the temporary station of the company at Indian Orchard, where they have a water power of 600 H. P. already in use.

Natchez, Miss.—Mayor W. G. Benbrook of this city has published notice that sealed proposals will be received at the office of the city clerk until Thursday, December 7, at 4 P. M., for lighting the streets, alleys, parks and public buildings of this city with electricity for a term of five years from March 1, 1894, in accordance with plans and specifications on file in said clerk's office.

San Francisco.—There is some likelihood that when the new Mission street electric road goes into operation the storage battery system will be used instead of the overhead wires. Under the direction of the officers of the road experimenting with the storage system has been in progress for some time and it is thought now that so far as the batteries are concerned every obstacle has been removed.

Bel Air, Md.—The United States Automatic Service Co. have shipped from Boston to Bel Air generators for 650 incandescent lights and 300 arc lights with equipments, for the purpose of lighting Bel Air and for railroad uses. The same company has asked for a franchise for laying rails through Bel Air, with the view of connecting it with the proposed electric railroad from Bel Air to Havre de Grace and Aberdeen.

Goshen, Ind.—The franchises and street railway so far constructed of the Indiana Electric Power Company have been sold at receiver's sale to Hatch & Chadwick, the contractors, for $20,000. The court also granted an order for the sale of the electric street railway of Elkhart for $40,000. The sales are in the line of a consolidation of the two companies, and the connection of Goshen and Elkhart by an electric road next spring.

Little Rock, Ark.—The city council has appropriated $30,000 for a new city electric lighting plant. The ordinance provides for an entirely new plant, with a new brick, slate roof, fire proof building on the site of the old one, with four sixty light dynamos, two engines—one a new one—entirely new modern-high tension machinery: the old plant to be taken in exchange for the new as part, but additional, payment to the $30,000.

New Haven, Conn.—The stock of the Edgewood Avenue Street Railway has been transferred to a new set of owners, principally New York capitalists. The new officers are: President, Winthrop G. Bushnell, of New Haven; vice-president and general manager, Fred. S. Wardwell, formerly of Duluth; secretary and treasurer, W. A. Spaulding, of New Haven; directors, including the above named gentlemen, Judge David Callahan, Harry I. Thompson and John S. Bradley.

Leavenworth, Kan.—The city council and Receiver Newman Erb of the Leavenworth Electric Railway Company being unable to agree on a franchise, all the horse cars were stopped by the receiver on the 18th, he announcing that the company will abandon the present street railway until such time as the council will permit it to be converted into an electric line. The company is changing the dummy line between the Fort and Soldiers' Home into an electric line as permitted by an old franchise.

Rome, N. Y.—The contract for the lighting of the city by electricity will be let in the spring if the authorities do not decide before that to install a plant to be owned by the city, a project which seems to be favored by many prominent citizens. The city charter says that a contract shall not be let by the council to extend over a year, but an effort will be made at the next session of the Legislature to have a bill passed whereby a contract for lighting the city may be made for a term of years.

Milwaukee, Wis.—The plant of the Milwaukee Electric Power and Light Company was to be sold on the 16th inst. to satisfy a mortgage of $10,000, but a half hour before the time for the sale friends of the company put up the money and the sale was declared off. There has been a reorganization of the company.—The Milwaukee Arc Light Company has been incorporated with a capital stock of $100,000, by Gottleib Wenninger, Henry A. Adler and Bernhard Conrad. The business will be to furnish electric light and power. The new company will use the plant of the Milwaukee Power and Lighting Company, which it purchased.

Denver, Col.—The Greeley circuit was opened by the Colorado Telephone Company on the 15th, adding Berthoud, Loveland, Fort Collins and Greeley to the system. The following places are now connected by telephone in Colorado: Denver, Alma, Black Hawk, Berthoud, Boulder, Canon City, Cassels, Central City, Clifton House, Coal Creek, Colorado Springs, Como, Deer Creek, Erie, Fairplay, Fort Collins, Georgetown, Greeley, Golden, Idaho Springs, Jefferson, Lafayette, Leadville, Littleton, Longmont, Louisville, Manitou, Monument, Morrison, Nevadaville, Pueblo, Rockvale, Silver Plume, South Pueblo and Williamsburg.

Brooklyn, N. Y.—Permission has been granted the Broadway Ferry and Metropolitan Company to change its motive power from horses to electricity.—A patent has been granted to T. A. Remsen, of Brooklyn, for an automatic switch for street railroads, particularly those operated with electric power, though the invention may be used upon any kind of a car. The switch is operated by means of an inner tread on one of the wheels, which, as the car approaches the switch, presses down a lever rising on the inside of the track to the height of the rail.

Chicago.—The telephone girls of the Chicago exchanges have organized the Chicago Telephone Operators' Beneficiary Society, with the following officers: President, Allie Timms; first vice-president, Nora Wells; second vice-president, Emma Doolittle; treasurer, Julia McMahon; financial secretary, Mary Kelly; corresponding secretacy, Ida Sylvester; recording secretary, Carrie Babcock; inspectress, Lizzie Jackson; outside sentinel, Lizzie Lane; sergeant-at-arms, Irene Dover; chaplain, Sarah Elder.

Cincinnati.—The Gas Company, after a prolonged struggle, has been granted the right to furnish electric lighting for public and private use for twenty-five years for 20 cents per thousand watts.—The Board of Aldermen have passed a series of resolutions providing for the extension of existing electric lines of the Cincinnati Street Railroad Company over existing horse-car lines, and subsequently provide that all the street railroad lines in Cincinnati shall be equipped for rapid transit, fare to be five cents, and the city to receive 5 per cent. of the gross receipts of all routes.

Philadelphia.—The *Inquirer* says: "The great success of the application of the trolley system of motive power to canal boats exhibited at the test made on the Erie Canal, near Rochester, last Saturday, has had the effect of stimulating interest in waterway transportation, and the fact was developed yesterday that for some time past a survey of the canal of the Schuylkill Navigation Company has been in progress with a view to determining its availability for the introduction of the trolley system. The result has been to demonstrate that there is no canal in the country to which electric traction can be applied so successfully or so cheaply."

New York.—The stockholders of the Edison Electric Illuminating Company have decided to issue $1,750,000 new bonds under the mortgage held by the Central Trust Company. The new issue is for purposes of construction. It will be devoted to the completion of the new building at Pearl and Elm streets, and to construct the underground system.—The Park Board has received a communication from the General Electric Company of Chicago, requesting the board to examine an electric fountain used during the World's Fair, with the idea of having it erected in Central Park. It was referred to Superintendent Parsons.—The Telephone Subscribers' Association hope to induce the State Legislature to pass a bill at the next session to cut down the present rental charged by the Metropolitan Telephone and Telegraph Company for instruments, $240 a year, to a reasonable figure. The company claims that $240 a year is a reasonable rental, alleging that its net earnings for the last two years have not averaged six per cent. on the actual cost capital invested and that the dividend has been less than 7½ per cent.

Rochester, N. Y.—"Some additional experiments," says the *Democrat and Chronicle*, "were made with the electric canal boat at Brighton yesterday (20th) in the presence of City Electrician Barnes, acting for the State authorities. Under the direction of Electrician Chesrown, of the Westinghouse Company, the rigid street railway trolleys, which were used in the experiment on Saturday, were replaced by flexible cables provided with simple hooks to attach to the trolley wires. By the use of this simple expedient the electricians were enabled to manipulate the boat to much greater advantage than on Saturday. With the boat lying at the berm bank, the trolley hooks were passed out to the trolley wires by means of a pikepole, and the hooks placed in position. The boat was then backed into the channel by the operation of the motors, and sent up the line at the speed of about four miles an hour. It passed under the bridges and through the lock, no difficulty being experienced with the improvised flexible trolleys. The boat was steered from one side of the channel to the other, and at the terminus of the line was turned around and started on its return trip, without the aid of the tug or pike poles. At the eastern terminus the boat was brought to its mooring place without the use of appliances other than the flexible trolleys. The voltage was about 300, and the current was somewhat less than on Saturday, leaving the developed electrical horse power about twenty as on the official trial."

The Seesawing of Arc Lamps.

Where arc lamps are run two in series on incandescent circuits much annoyance has been caused by their interfering with each other's regulation, the result being an alternate feeding and separating of the carbons which has been termed "seesawing." For those who do not wish to go into theory of this action, the simple analogy in the accompanying cut may be interesting. It will be remembered that all lamps of this class have the feeding mechanism controlled by two magnets, one being on the main circuit and in series with the arc itself, while the other is a shunt around the arc. Then as the carbons burn away and the arc lengthens, the comparative resistance of the two paths for the current changes and allows the lamp to feed the carbon. In the case of series lamps the main current is kept practically constant by the dynamo or its regulator, and the voltage at the lamp varies. But with a pair of lamps on a constant potential circuit the sum of the voltages remains unchanged, so that the increased consumption at one lamp will rob the voltage from the other, and vice versa. In other words the left hand arc in the cut will have very little counter-electromotive force, so that most of the voltage will be left for the other one and will draw the right hand pair of carbons far apart. But this action exaggerates the difference in voltage still more, until the left hand arc touches its carbons and then separates. In this way one pair of carbons will approach while the others are separating, the action being just as if they had a mechanical lever suspension as pictured. Mr. George Cutter, of Chicago, holds this matter of seesawing to be one of the greatest problems met in adapting arc lamps to incandescent circuits, but he thinks it is well met by the peculiar design of the Waterhouse lamps, and it is said that users bear out his statement. At any rate the pictured analogy is interesting as showing a drawback which has at last been overcome.

THE SEESAWING OF ARC LAMPS.

Queen & Company's Non-Inductive Direct Current Wattmeter.

A dynamometer wattmeter constructed so as to work satisfactorily on alternate current circuits will work with equal satisfaction on continuous current circuits. The reverse, however, is not true. Masses of metal in proximity to the moving parts introduce no errors in continuous current measurements, but in alternate current measurements their presence becomes fatal. Aside from a metal case, small pieces of metal near the system, and even the binding posts on the outside, are likely to introduce serious errors. Not only this but the inductance and capacity of the fine wire or potential circuit must also receive consideration.

The instrument shown in the Figure is constructed on the inclosed dynamometer principle, the case being of brass mounted on a wooden base built up of a number of sections to prevent warping. The extra resistance, about 3,000 ohms for a 110 volt circuit, is wound non-inductively and in sections on wooden spools placed inside the base, which is suitably ventilated. Within the case, half of which may be easily removed, are to be found both the fixed and movable coils, the latter coil consisting of from 100 to 200 turns, depending on the range desired, of No. 34 copper wire wound on a light mica form. This coil is suspended from a rigid support by means of a fine phosphor bronze strip 1⅛ inches long, a spring being provided at the bottom for the return current. Suitable guides and a clamping device are provided, the former to prevent the coil from being used when slightly out of centre due to improper leveling. A spiral spring attached to the torsion head serves as the control. The upper end of the pointer attached to the system plays over the zero of the scale, the same as in the dynamometer. The use of mercury being entirely avoided renders the instrument perfectly portable, and the employment of a large amount of extra resistance, along with the delicately constructed and suspended system, reduces to a minimum the power consumed by the wattmeter itself, and at the same time leaves it quick to respond to any change in the power being measured. In order that the instrument may be applicable throughout a wide range of current, two pairs of fixed or current coils are provided, the one pair consisting of ten turns each with a carrying capacity of 25 amperes, and the other of one turn each with a carrying capacity of 250 amperes, placed over the other coils. Thus, either 25 or 200 amperes may be made to effect a complete revolution of the torsion head. The potential circuit may be made applicable to the higher voltages by the mere insertion of more extra resistance.

Premier Motors and Batteries.

M. R. Rodrigues, manufacturing electrician, 17 and 19 Whipple street, Brooklyn, has been actively engaged lately in making small electric railway cars to be run by his No. 1 Motor, an exceedingly interesting contrivance for the pleasure and edification of young folks who are fortunate enough to get them as presents during the holidays or at any other time. The car is about twelve inches long and the truck four inches gauge. It will carry over eight pounds at good speed. It is provided with a reversing switch of Mr. Rodrigues's design which automatically reverses current, and the car can run on straight, serpentine, horseshoe or circular track. The complete outfit, with eighteen feet of track, costs only $25.00. Samples can now be seen at the manufactory at above address.

Mr. Rodrigues's motors and batteries have a wide sale, and are highly approved by the trade. During the past week he has shipped motors and bluestone batteries to Central America, and has a large order for a full line of motors and the new No. 2 Premier Battery for a California State Fair exhibit.

The E. P. S. Company's Batteries.

The Birmingham Central Tramways Company, England, after trying plates of other manufacturers for more than a twelvemonth, decided to renew the whole of the battery with plates manufactured by the E. P. S. Company.

Two batteries of the original plates manufactured by the Electric Construction Corporation (the then owners of the E. P. S. patents), supplied more than two years ago, have been regularly working and giving excellent results. The following order speaks for itself:

Birmingham Central Tramways,
November 10, 1893.
To ELECTRICAL POWER STORAGE CO. LTD.
4 Great Winchester Street, E. C.

Dear Sirs: With reference to your favor of the 1st inst., we beg herewith to order from you on behalf of the Birmingham Central Tramways Company: 960 Positive Sections each of nine plates: 960 Negative Sections each of ten plates. Yours faithfully,

KINCAID, WALLER & MANVILLE.

The Worthington Condenser in Electric Lighting Plants.

Many of the plants that were erected during the early period in the history of electric lighting were located but the advice of qualified steam engineers or the benefit of advanced practice. The boilers and engines were not by any means the most economical, but answered well for time.

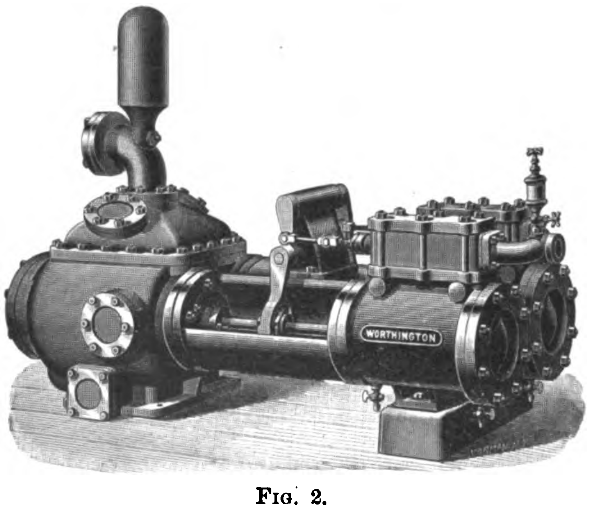


Fig. 2.

A large number of steam engines in electric lighting lants are situated so that an adequate supply of water can easily be had for condensation, but are at the present time non-condensing. They are laboring under a back pressure of 14.7 pounds that is caused by exhausting against the atmosphere, where they should by all means be run condensing.

The value of a vacuum to an engine under normal conditions is at a low estimate equal to 25 per cent. of the power developed by the engine running non-condensing. This means that by the use of a Worthington Condenser the coal consumption can be reduced one-quarter to one-fifth with the same production of light, or the number of lights may be increased a fifth without burning more fuel.

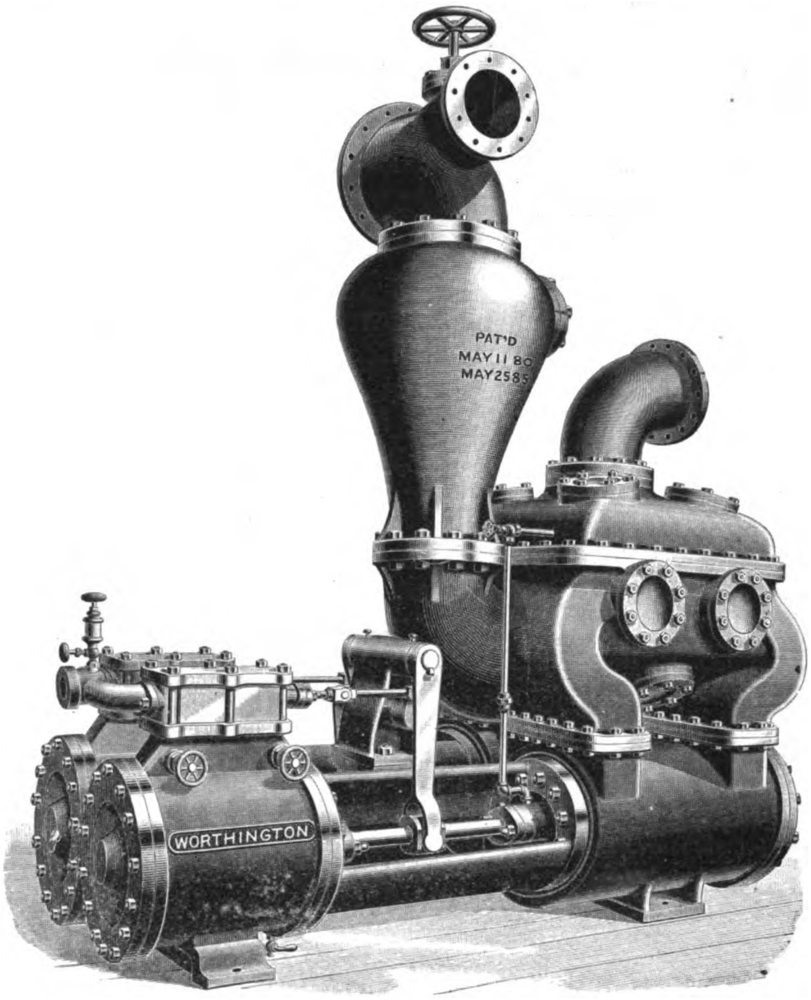

Fig. 1.

It is hardly necessary to more than intimate that this result is acceptable to any electric lighting company, and that this matter of Worthington Condensers, as an adjunct to dynamo engines, should have the most careful consideration.

In cotton mills the steam plants are carefully arranged and have the attention that is necessary to insure the highest economy, and condensing engines are quite generally used; but the money paid for coal is of small importance when compared with the value of cotton manipulated by the company. Flour mills are also large users of power, and every effort is made to have the fuel bill as small as possible, but still the much greater cost of the wheat places the cost of the coal in a secondary position.

With electric light and power companies, however, the thing is very different; the cost of fuel is the great expense of maintenance. By the combustion of coal a latent energy is aroused, which, through the agency of steam and the steam engine, becomes motive power. The function of the dynamo is to change this power into its equivalent electricity and electricity in turn produces light. This light is the material that the company offers for sale. The cost of the light is dependent primarily upon the cost of the coal, and any increased economy of the boilers or engines, improved belt transmission or dynamo efficiency, directly affects the profits in nearly like proportions.

Upon changing an engine from non-condensing to condensing it is found that the boiler pressure in many cases may be lowered fifteen to twenty pounds with nearly as high results. Doing this often lengthens the life of the boilers considerably, and is very desirable to such as have had long service.

Fig. 2 illustrates the ordinary Worthington pump having two double-acting pistons and fitted with water valves of rubber or metal as required. These pumps are designed for boiler feeding, fire, hydraulic elevator and general service.

Morse's Lightning Calculator.

Messrs. Cushing & Morse, General Western Agents for Day's Kerite Wires and Cables, 225 Dearborn street, Chicago, are distributing to the trade and friends a new device for determining at sight the size wire required for any number of incandescent lamps any distance from point of distribution. It is not a cumbersome book of tables, but consists of two cardboard disks on a single pivot. You simply multiply the distance by the number of lamps; the result is the number of lamp feet. You then turn your disk to the nearest corresponding number, and the size wire wanted, at any percentage of loss, is at once indicated.

As there may be many persons in their territory whom they unintentionally have overlooked, they desire that all such send their address to them and they will receive this really valuable article.

An Electric Car Elevator.

An electric car elevator has recently been placed in the Bartlett Street Car House of the West End Street Railway Company, Boston, which is probably the largest electric elevator in the United States.

The platform of this elevator is 40 feet long, 12 feet wide, weighs some five tons and carries a system of locks which support the platform at the floor, rendering it rigid while running on and off the heavy cars. The machine is supported on I beams directly over the wellway.

It comprises a system of gearing so constructed that friction is reduced to a minimum, and the power applied to move the load is distributed over the whole area of the platform.

The elevator is of very simple and efficient construction;

it raises the heavy cars quickly and easily, and is under the perfect control of the operator. It was built by Geo. T. McLauthlin & Company, 120 Fulton street, Boston, who have constructed a similar elevator for the Union Railroad Company, Providence, R. I.

Commercial Notes.

The Metropolitan Electric Company, Chicago, are receiving a great many orders for the Paiste Adjustable Clutch for T.-H. Arc Lamps. This is the only clutch made that can be adjusted to the carbon rod, and can never wear out. They are also selling the Paiste Lower Contact Bushing for T.-H. Arc Lamps. This bushing insures a perfect contact to the carbon rod without the aid of small brushes.

On December 1 Cummer, Craig & Company will consolidate their office, stock rooms and workshop at No. 69 Broad street, Boston, Mass. With increased facilities they will be able to exhibit the productions of the manufacturers for whom they are selling agents, to wit: American Wire Glass Manufacturing Company, Bishop Gutta-Percha Company, Crocker-Wheeler Electric Company, Frisbie Elevator and Manufacturing Company, General Incandescent Arc Light Company, Interior Telephone Company, Star Electric Lamp Company, Waddell-Entz Company.

INCORPORATIONS.

The Monett Electric Light, Power and Ice Company, Monett, Mo.—to manufacture electric light, power and ice. Capital stock, $50,000. Promoters: D. J. Young, Fort Smith, Ark.; J. F. Carr, Springfield, Mo.; W. T. Hamilton, Monett.

The Georgetown Water and Electric Company, Georgetown, Texas—to supply water, light, heat and power to the public. Capital stock, $100,000. Promoters: A. S. Fisher, W. K. Makemson, E. E. Taylor, J. W. Robertson, Georgetown, Tex.; W. L. Vining, Austin, Tex.

Wauconda Telegraph and Telephone Company, Wauconda, Ill. Capital stock, $2,500. Incorporators: A. J. Coykendall, Robert Harrison and others.

The Globe Electric Light Company, Portland, Me.—to manufacture and deal in all kinds of lamps for electrical and other uses. Capital stock, $300,000. Promoters: Reinold Berrenburg, Carl Bartels, Joseph P. Sprang, all of Boston, Mass.

The Home Industrial Association, Port Angeles, Wash.—to operate electric light and power plants, water works, etc. Capital stock, $50,000. Promoters: Geo. Venable Smith, J. F. Smith, Thos. Jarvis, J. E. Beam, Elliott E. Beaumont, Port Angeles.

The Freeland Electric Light, Heat and Power Company, Freeman, Pa.—to supply light, heat and power by electricity to the public of Freeland, etc. Capital stock, $15,000. Promoters: Fred. W. Bleckley, Scranton, Pa.; Harry E. Sweeney, Drifton, Pa.; Wm. H. Boyer, Scranton, Pa.

The Commercial Electrical Engineering Company of Detroit, Mich., has filed articles of incorporation. Capital stock, $50,000.

The South Jersey Electric Company, Jersey City—to generate and supply electricity to be used for motors, lighting and heating, and the manufacture of all machinery and appliances used in electrical business. Capital stock, $100,000. Incorporators: Dr. Henry A. Mandeville, William H. Curtis, Stevenson Constable, J. R. Weeks, Frank Brewer, Frank A. Wright and Charles A. Cregan.

The Conduit Construction Company, New York City—to construct electrical conduits in connection with electrical railways; to introduce improved methods of propelling street and tram cars by underground trolleys, and to replace street railroad tracks and install thereon improved devices for propelling cars electrically. Capital stock, $25,000. Directors: Thomas C. Buck, Charles W. Keep and Julien Meyers, of New York City; Robert L. Keon, of Montclair, N. J., and John J. Green, of Boonton, N. J.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 14, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

508,472. Fender for Electric Cars, etc. Caleb N. Homan, Lawrence, Mass. Filed Jan. 9, 1893.

508,538. Electric-Railway Trolley. James Chase, Rochester, N. Y. Filed April 8, 1893.

508,539. Electric-Railway Trolley. Stephen D. Field, Stockbridge, Mass. Filed March 2, 1891.

508 578. Conduit for Electric Railways. Archibald J. Robertson, New York, assignor to himself, George S. Brush, Brooklyn, and Henry Carey, Elm Park, N. Y. Filed Jan. 6 1891. Renewed April 4, 1893.

508,615. Electric Railway. John C. Henry, Westfield, N.J. Filed Sept. 10, 1892.

508,622. Electric-Railway Trolley. Walter H. Knight, New York, N. Y. Filed Aug. 10, 1888.

508,633. Electric-Railway Motor. Edward D. Priest, Lynn, assignor to the General Electric Company, Boston, Mass. Filed Feb. 23, 1893.

508,669. Trolley for Electric Railways. Norman C. Bassett, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed July 18, 1892.

508,672. Switch for Electric Railways. Edward M. Bentley, New York, N. Y. Filed Aug. 31, 1889.

508,673. Brake Apparatus for Electrically-Propelled Cars. Francis O. Blackwell, New York, N. Y., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Sept. 16, 1889.

508,743. Electric-Railroad-Track Cleaner. Hugh O'Connor, Passaic, N. J. Filed June 26, 1893.

508,771. Construction of Trolley-Lines. George Q. Seaman, Brooklyn, N. Y., assignor to himself, Alexander Wilson and William Jones, same place. Filed July 22, 1893.

508,805. Electric Brake for Railways. Armand de Bovet, Paris, France. April 23, 1892.

508,807. Converter System for Electric Railways. Charles S. Bradley, Yonkers, N. Y. Filed May 31, 1887.

ELECTRIC LIGHTS AND APPLIANCES.

508,482. Electric Lamp for Bicycles. George Mayr, Brooklyn, assignor of one-half to Elkin Farmer, New York, N. Y. Filed March 27, 1893.

508,559. Electric-Lighting System. Theodore A. Willard, Norwalk, Ohio, assignor to the United States Wind Engine and Pump Company, Batavia, Ill. Filed Aug. 29, 1893.

508,616. Electric Car-Lighting System. John C. Henry, Westfield, N. J. Filed April 3, 1893.

508,623. Stand for Testing Electric-Arc Lamps. Edward R. Knowles, Middletown, Conn., assignor to the Schuyler Electric Company of Connecticut. Filed Nov. 29, 1892.

508,642. Search-Light. Albert L. Rohrer, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 20, 1892.

508,647. Electric-Lighting System. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Aug. 12, 1891.

508,656. Electric-Arc Lamp. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 4, 1892.

508,659. Leading-In Wire for Incandescent Lamps. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed May 23, 1892.

508,678. Apparatus for Treating Filaments for Incandescent Electric Lamps. Henry D. Burnett, Lynn, and Samuel E. Doane, Swampscott, Mass., assignor to the General Electric Company of New York. Filed Aug. 23, 1893.

DYNAMOS, MOTORS, ETC.

508,493. Method of Regulating Self-Exciting Alternate-Current Electric Generators. William Stanley, Jr., Great Barrington, Mass., assignor to the Westinghouse Electric and Manufacturing Company, Pittsburg, Pa. Filed Oct. 18, 1888.

508,624. Brush-Holder for Dynamo-Electric Machines. Edward R. Knowles, Middletown, Conn., assignor to the Schuyler Electric Company of Connecticut. Filed March 20, 1893.

508,630. Fluid-Pressure Device for Controlling Electric Motors. Horace F. Parshall, Lynn, Mass., and John W. Darley, Jr., Baltimore, Md., assignors to the General Electric Company, Boston, Mass. Filed May 6, 1893.

508,634. Mounting Armatures for Dynamo-Electric Machines. Edward D. Priest, Lynn, assignor to the General Electric Company, Boston, Mass. Filed May 15, 1893.

508,636. Connector for Dynamo-Electric Machines. Henry G. Reist and Jonathan P. B. Fiske, Lynn, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed July 3, 1891.

508,639. Machine for Boring out the Standards and Field-Magnets of Dynamo-Electric Machines. John Riddell, Saugus, assignor to the Thomson-Houston Electric Company, Boston, Mass. Filed Aug. 26, 1892.

508,649. Protection for the Insulation of Dynamo-Electric Machines. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Aug. 26, 1891.

508,658. Dynamo-Electric Machine or Motor. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed May 23, 1892.

508,710. Fan Motor. Warren S. Hill, Hyde Park, Mass. Filed June 7, 1893.

508,721. Alternating-Current Motor. John F. Kelly and Cummings C. Chesney, Pittsfield, Mass., assignors to the Stanley Laboratory Company, same place. Filed Jan. 16, 1893.

508,880. Electric Generator. Warren S. Hill, Hyde Park, Mass., assignor to the W. S. Hill Electric Company, Portland, Me. Filed April 12, 1893.

BATTERIES.

508,'51. Battery Element. William Mills, Elizabeth, N. J., assignor to the New York Carbon Works, New York, N. Y., and Newark, N. J. Filed Oct. 18, 1892.

508,897. Battery Element. William Mills, Elizabeth, N. J. Filed Nov. 11, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

508,829. Telephone-Transmitter. Eloy Noriega, Mexico, Mexico. Filed Feb. 4, 1891.

508,830. Electric Telephone. Eloy Noriega, Mexico, Mexico. Filed Aug. 25, 1892.

SWITCHES, SWITCHBOARDS, ETC.

508,625. Switch-Box for Controlling Electric Circuits. Edward R. Knowles, Middletown, Conn., and Edwin H. Park, Millbury, Mass., assignors to the Schuyler Electric Company of Connecticut. Filed March 31, 1893.

508,626. Stand for Controlling Electric Circuits. Edward R. Knowles, Middletown, Conn., assignor to the Schuyler Electric Company of Connecticut. Filed May 10, 1893.

508,638. Means for Regulating Multiphase Currents. Edwin W. Rice, Jr., Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Jan. 19, 1892.

508,641. Switchboard for Power-Stations. Albert L. Rohrer, Lynn, and George W. Mansfield, Melrose, Mass., assignors to the Thomson-Houston Electric Company of Connecticut. Filed March 5, 1891.

508,646. System of Electrical Distribution. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 19, 1890.

508,838. Electric Distribution. Edwin W. Rice, Jr., Swampscott, assignor to the General Electric Company, Boston, Mass. Filed May 13, 1893.

508,839. System of Electric Distribution. Edwin W. Rice, Jr., Swampscott, assignor to the General Electric Company, Boston, Mass. Filed May 31, 1893.

508,898. System of Electric Distribution. Walter S. Moody, Lynn, assignor to the General Electric Company, Boston, Mass. Filed March 17, 1893.

TRANSFORMERS.

508,422. Current Transformer. William H. Hornberger, Elkhart, Ind. Filed Dec. 17, 1892.

508,650. Electrical Transformer. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Aug. 28, 1891.

508,654. Cooling Transformer. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 4, 1892.

508,655. Electric Transformer. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 4, 1892.

508,688. Electric Transformer. Axel Ekstrom, Lynn, Mass., assignor to the General Electric Company of New York. Filed Nov. 16, 1892

MISCELLANEOUS.

508,489. Device for Indicating Synchronism. Charles F. Scott, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed Sept. 28, 1892.

508,518. Electric Door Opener. Harry T. Johnston, New York, N. Y. Filed May 19, 1893.

508,618. Underground Electric Conductor. John C. Henry, Westfield, N. J. Filed Aug. 8, 1892.

508,620. Field Magnet Coil and Method of Manufacturing Same. Joseph Johnson and Caryl D. Haskins, Lynn, Mass., assignors to the General Electric Company of New York. Filed May 2, 1893.

508,629. Safety Cut-Out. Olof Offrell, Middletown, Conn., assignor to the Schuyler Electric Company of Connecticut. Filed Dec. 5, 1892.

508,632. Electric Arc Disrupter. William B. Potter, Lynn, assignor to the General Electric Company, Boston, Mass. Filed July 13, 1893.

508,637 Armature Core. Henry G. Reist, Lynn, assignor to the General Electric Company, Boston, Mass. Filed May 24, 1893.

508,643. Connector for Electro-Magnet Coils. Martin O. Southworth, Lynn, assignor to the General Electric Company, Boston, Mass. Filed Jan. 31, 1893.

508,648. Lightning Arrester. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Aug. 26, 1891.

508,651. Contact Apparatus. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Sept. 17, 1891.

508,652. Electric Cut-Out. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Sept. 17, 1891.

508,653. Insulating Composition. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Nov. 2, 1891.

508,657. Reactive Coil. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 15, 1892.

508,660. Detector for Electric Current Meters. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed Nov. 25, 1892.

508,661. Electric Meter. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed May 12, 1893.

508,662. Indicating Apparatus for Electric Circuits. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed July 1, 1893.

508,674. Rheostat. John B Blood, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Feb. 23, 1892.

508,680. Electric Elevator. Arthur T. Chase, Cambridge, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Dec. 16, 1891.

508,687. Cleat for Electric Wiring. Frederic A. Duggan, Trenton, N. J. Filed June 28, 1893.

508,691. Electric Elevator Controller. Jonathan P. B. Fiske, Lynn, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed July 18, 1891.

508,692. Rheostat for Controlling Electrically Operated Dental Apparatus. Jonathan P. B. Fiske, Lynn, assignor to the General Electric Company, Boston, Mass. Filed July 10, 1893.

508,804. Process of and Apparatus for Dissociating Salts of Alkalies by Electrolysis. Henry S. Blackmore, Mount Vernon, N. Y. Filed Sept. 8, 1892.

508,827. Magnetic Permeameter. Edgar D. Knap, Schenectady, and Severn D. Sprong, East Greenbush, N. Y. Filed June 28, 1893.

To Inventors and Others.

United States and Foreign Patents Procured.

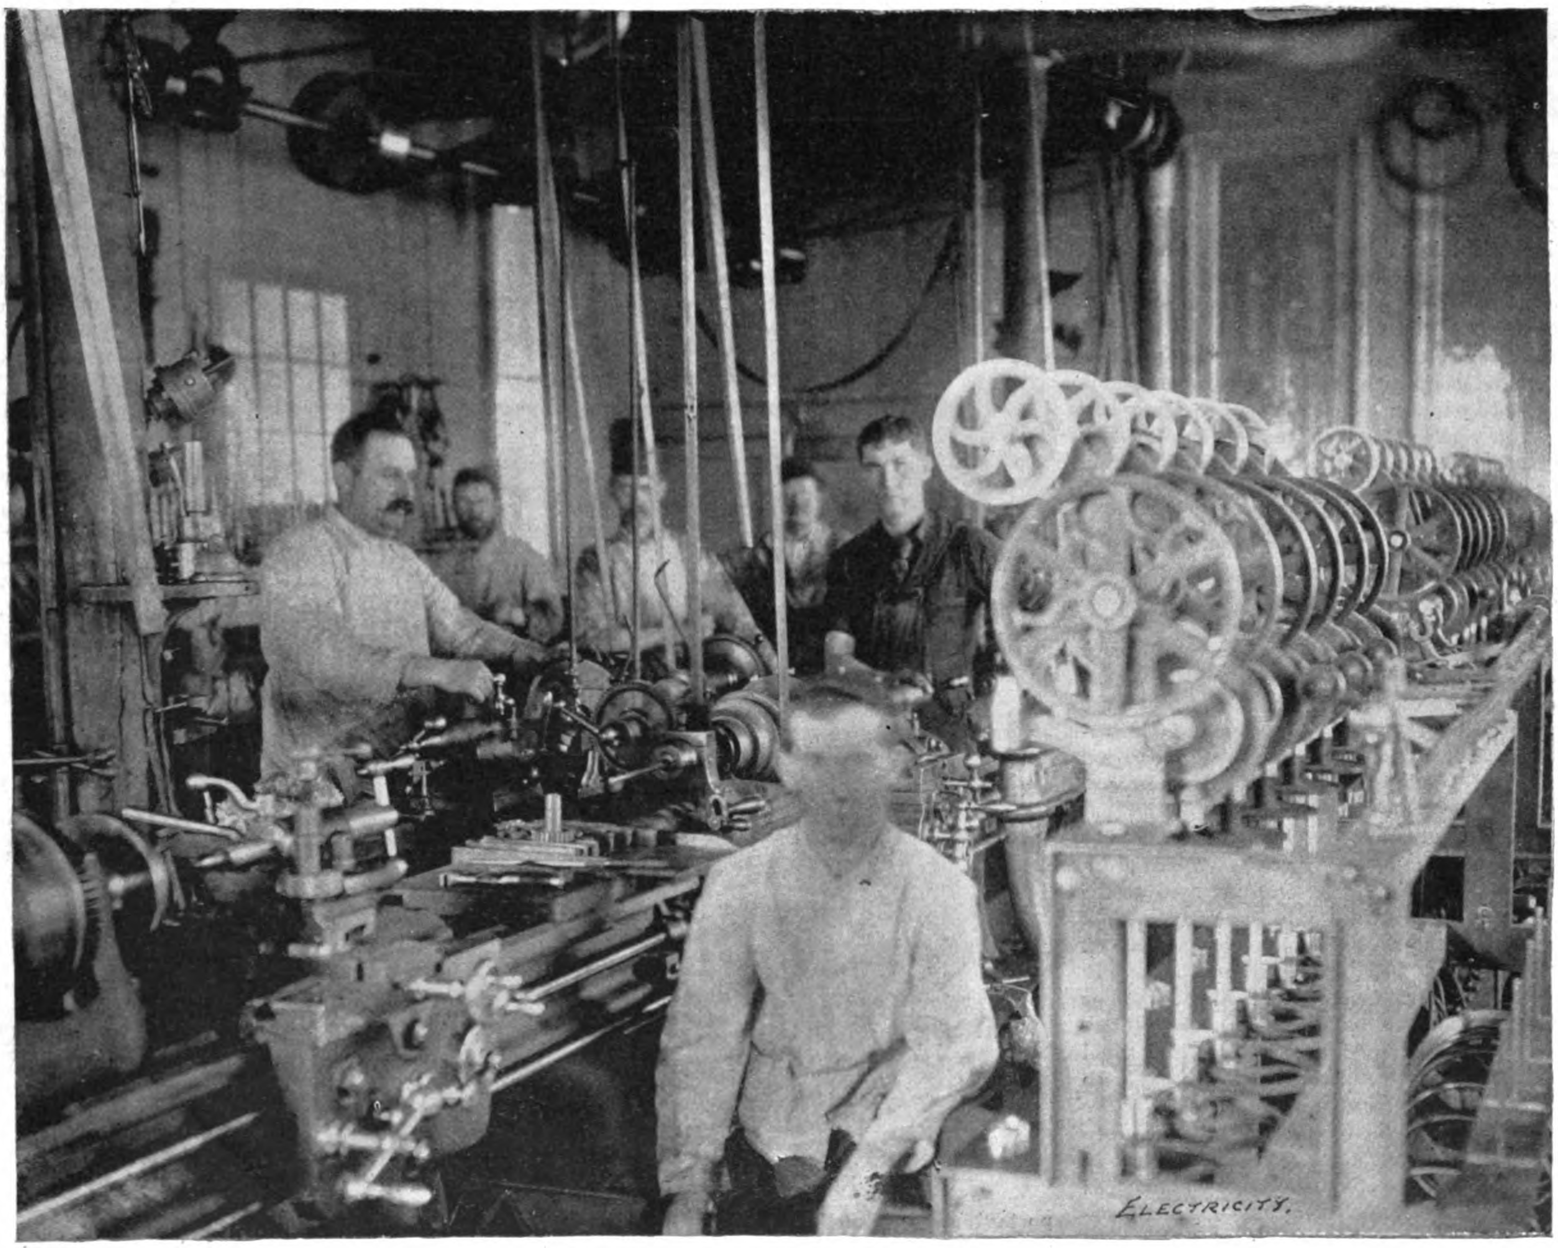
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. DECEMBER 6, 1893. CHICAGO. No. 21

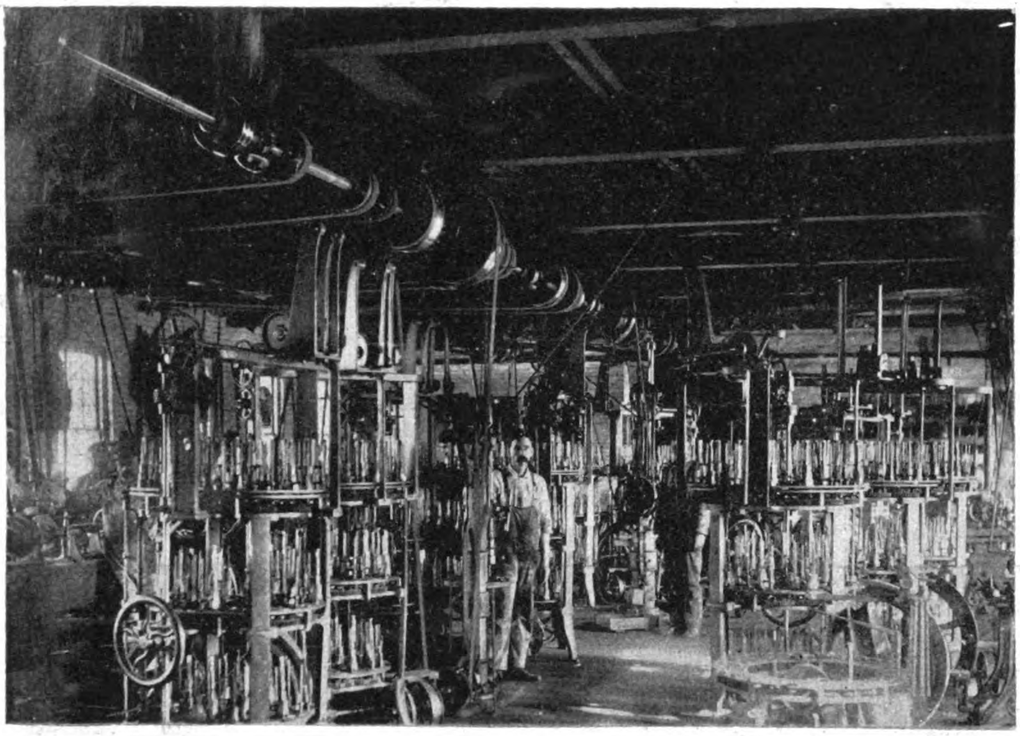


NEW ENGLAND BUTT COMPANY—MODEL ROOM. (SEE PAGE 246.)

New England Butt Company.

A Brief History of a Great Manufacturing Concern—Its Enterprise and Productions.

The city of Providence, R. I., is entitled to rank as one of the foremost cities in the United States for the diversity of its manufactures of an engineering and electrical character, its famous engines, electric cables and wires, fine engineering tools, locomotives and other apparatus being known all over the world. It was in Providence that some of the earliest engineering works and foundries were established, and the fine reputation made years ago is still maintained and is surpassed by none; hence it is that so many factories of various kinds have been equipped by the genius and skill that have found a habitation and a name in the capital of "Little Rhody."



New England Butt Company—Braider Machine Shop.

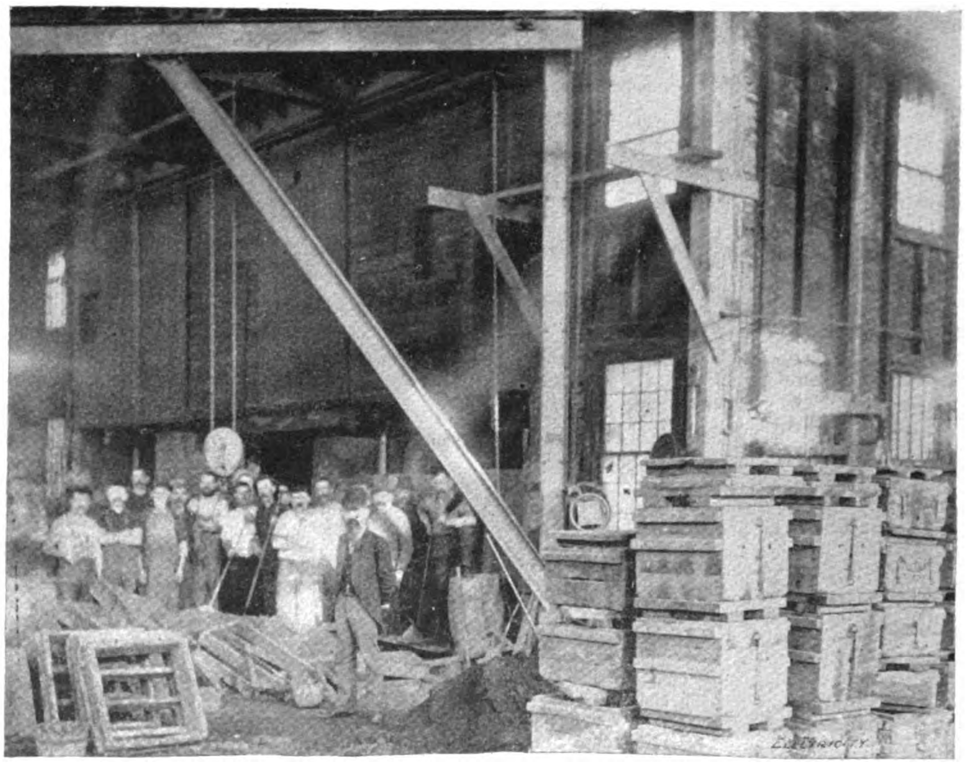
In Providence is located the well known firm whose title, familar to everybody, appears at the head of this article.

It is now over half a century since Mr. Nicholas A. Fenner established himself in Providence as a manufacturer of butt hinges, a specialty which was embodied in the original title of the concern and which is still retained, though the manufacture of that particular class of goods today forms but a small part of the large and varied business now done by this prosperous company. Fifty years ago this country had entered on that period of growth and development which has known few, if any, pauses in the march of progress. The laying out and building up of towns and cities from the Atlantic to the Pacific called for an enormous output of builders' hardware, and hinges formed an important item. To supply the extraordinary demand Mr. N. A. Fenner contributed largely by his genius, skill, enterprise and push. Soon the fame of his goods had reached everywhere and the market became so wide that his manufacturing facilities had to be constantly increased. Gradually he worked into other lines, and began the manufacture of a large variety of domestic or household appliances wrought in metal, until he ranked as the foremost in his line of business.

Then, as time rolled by, the manufacturing industries of the land required special machinery of many kinds, and so, gradually, the hinge factory became an engineering works of considerable importance. First-class engineers, draughtsmen, iron-founders and machinists only were employed. Inventors needing their inventions developed and perfected soon found that the managers of this company were the men with whom to trust their ideas, with the assurance that they could and would be worked out there satisfactorily if anywhere. Thus it was that the Butt Company rapidly expanded into one of the best and most widely known firms in the country, and enjoyed a measure of prosperity and success of which any firm might be proud. Then when the electrical business took tangible shape and bore evidence of some day becoming an important factor in modern civilization, the managing head of the New England Butt Company was not slow to appreciate the prospective possibilities of the new business, and began the designing and manufacture of braiding machines for covering electric wires. In this they soon became as successful as in every other department, and ere long had on the market some of the very best machines known to the trade. All and everything that human ingenuity could devise was incorporated in these various machines, and the demand for them grew rapidly. Everything in the shape of a machine for preparing wires, whether small or large, to be used for the transmission of the electric current was designed, made and sold; and so high class in material and workmanship, as well as efficient in design, were these special devices that they quickly assumed a foremost position on the market and commanded a ready sale everywhere.

This necessitated frequent enlargements of their facilities and the employment of more hands, until in a few years the works covered several acres. But the manufacture of braiding machines did not by any means exhaust the resources of this company. They branched forth into the manufacture of machinery for making cables, tapeing machines, both vertical and horizontal, for covering wires with adhesive tapes; also winding machines.

To attempt to describe any or all of these machines in an article like the present one would be impossible; they are so full of detail, so ingenious in construction and perfect in operation that they have been adopted by almost every manufacturer of electric wires and cables throughout the world. As we have said, these machines are made for covering wires of all diameters up to armoring of submarine cable and down to the finest magnet wires. These processes are carried on not with short lengths simply, but are so adapted that wires of any required length can be as easily manipulated. A great many of these machines have been made and shipped. Hundreds of them are now in use in South America, England, all over Europe, and even China and Japan are good customers. Machines are also made for the manufacture of fancy trimmings such as are now in such general use for ladies' wearing apparel—indeed, the machines of this company are adapted for every conceivable use.



New England Butt Company—A Corner in the Foundry.

Determined to keep up with the times, the New England Butt Company went more extensively into the electrical business, and with the extensive foundry they were running they undertook the manufacture of high-grade castings for all electrical purposes, and soon achieved distinguished success. One of their largest departments, both foundry and machine shop, is kept constantly running on electrical work; and having made a close and thorough study of the making of castings of the right magnetic quality for electrical work, this company enjoys an enviable reputation for this class of castings. They possess one of the largest and best equipped foundries in the country. Their mixtures of iron for the electrical business cannot be surpassed; and in the finer and smaller castings, as well as the larger and heavier ones, they do a business aggregating many hundreds of tons every year, and every one of their customers has learnt to know that the orders entrusted to the New England Butt Company will be filled in a manner that leaves nothing to be desired.

The Frontispiece and illustrations, showing interiors of some of the shops, together with a portrait of Mr. H. N. Fenner, son of the original founder of the firm, and now the treasurer and general manager of this prosperous company, will give some idea of the general character of one of the best known firms in the country, and one to whom the electrical fraternity is largely indebted for most valuable aid in the development of the great electrical industry.

H. N. FENNER,
Treasurer and General Manager of New England Butt Co.

A Mammoth Chimney.

The Division Avenue electric plant of the Brooklyn City Railroad Company is regarded as the largest in existence, and its massive chimney has taken its place among the wonders of the world. It surpasses every chimney known in the world in the size of its flue, the latter measuring 17 feet. The chimney is 332 feet 8 inches in height. At Glasgow, Scotland, there is a chimney 425 feet high, but its flue does not exceed 9 feet in diameter. The chimney at Frieberg, in Saxony, has a height of 552 feet 6 inches, but its flue is several feet less in diameter than the Brooklyn chimney. Other chimneys in this country exceed the Brooklyn chimney in height, but none is said to equal it in capacity. Thirty-six boilers will feed their smoke to the great shaft. These will run six engines of 1,000 horse power each. This is the minimum power, but each engine can be counted on for nearly 50 per cent. increase in that figure, which will make the combined power aggregate nearly 10,000. The big building, or series of buildings, which in conjunction with the boilers, engines, dynamos and the big chimney form the company's plant, has a fronting on the river of 281 feet. The depth from Kent avenue on the south side is 255 feet, the depth on the northern or Division avenue side is 216 feet, and the frontage on Kent avenue is 173 feet. Fully $60,000 has been expended in the erection of the chimney, and the total expenditure in the plant as a whole will approach $3.000.000. The consulting engineer of the work was F. S. Pierson and the chief engineer M. G. Starrett.

Electricity in the U. S. Weather Bureau Exhibit at the World's Fair.

BY C. W. SWOOPE.

A little to the west and north of the Government Building in the "White City" stood a small, neat, and apparently an insignificant building, known as the United States Weather Bureau Station and Exhibit. No doubt many passed this little building in their tour of the grounds, but the casual observer who chanced in ought to have felt well paid for his curiosity, for here the Government had gone to considerable pains to give the public an opportunity to see, understand and learn the mysteries of the Weather Bureau Service and just how "Uncle Sam's Prophets" decided what the future condition of the weather was going to be. The station was fitted up similarly to those established throughout the country, and all of the instruments were in actual working order, thus affording an excellent opportunity to those interested in meteorolgy.

We read naturally enough in the daily papers the reports and statistics of the Weather Bureau Service, but how few realize and understand how such results are obtained. It is in formulating and gathering these results that electricity plays such an important and useful part, much material progress having been made in the last few years, as will be seen in the instruments manufactured to-day for such purposes, which would not be possible were it not tor electricity.

One of the most interesting instruments on exhibition was the anemometer, used in measuring the force or velocity of the wind. It consists of two parts, the revolving vanes or anemometer proper and the graphical recording instrument.

The former consists of four hollow hemispherical cups, the concave parts facing in the same direction around a circumference, mounted upon cross arms at right angles to each other. At the intersection of the cross arms they are fastened to a vertical axis suitably supported but free to move with a small amount of friction. Upon the lower end of axis is an endless screw which gears into a train of wheels connected with a dial in such a manner that every revolution of the axis is mechanically recorded. The relation between the speed of the revolving cups and the wind is known, so that the dial is calibrated to read so many revolutions of axis equal to one-mile wind velocity. The dial so records this, and at every mile (so many hundred revolutions, as 500) electrical contact is mechanically made with two wires leading from this exposed instrument to the recording register located indoors. The latter consists of a drum actuated by a clock mechanism, an electro-magnet, and a recording pen influenced by armature of magnet; upon the drum is fastened a ruled paper scale, upon which the record is recorded. Thus, the drum revolves a certain space per period of time, and each mile wind velocity being recorded, we have upon inspection of a record the rate of wind velocity in miles per hour, etc. Scales are prepared for drums to be replaced every twenty-four hours, or a weekly record may be taken by slowing down speed of drum, fifty-two records being much more readily handled than three hundred and sixty-five sheets of paper. The instrument or registering portion much resembles some forms of graphical recording voltmeters now upon the market.

The anemoscope, for indicating the wind direction, utilizes the electric circuit in a similar manner for recording the directions graphically. The common form of weathervane in shape of an arrow is used. Upon the lower end of the vertical revolving axis is mounted a body upon which are four cams; leading off spring contacts press upon each of these, and the cams are so adjusted with reference to the position of the vane that for each particular position, such as north, an electric circuit will be completed through one of the sliding contacts; thus each of the four cardinal points of the vane completes a separate circuit through the sliding contacts. The contact spring is quite novel and somewhat different from the brush used on small dynamos. A roller or disc is mounted on a shaft held in place by two arms and a spring pressing against the same; thus while the cams revolve in one direction, the discs revolve in the opposite direction. It was designed to eliminate friction loss. Such a form of sliding contact might be used as a brush for dynamos, but its disadvantages would most likely outweigh its advantages.

The recording register, besides the drum and clock mechanism, contains four electro-magnets, one for each of the four circuits, north, east, south and west. One pole of the battery passes direct to the four cams, while the other goes to a switch in the clock, and is then completed through the magnets and contact springs. The switch in the clock is closed and again broken each minute, thus influencing the recording pen in a particular direction according to the electro-magnet in circuit. On open circuit the pen produces a straight line; thus is given the graphical record of the wind direction on one sheet of paper every minute for a day or week as the case may be. Combining the records of the anemometer and the anemoscope, we have the rate of velocity of the wind in every direction.

Two forms of instruments were exhibited for recording the hours of sunshine. In one the sun was permitted to pass through a small aperture in the instrument and affected a sheet of sensitized paper in different portions for the various angles of the sun. Upon being developed the paper showed a line, the intensity of which indicated the record of sunshine.

A more interesting instrument was the electrical sunshine recorder, recently invented and adopted by the U. S. Weather Bureau. This instrument is composed of a glass tube with a small bulb blown at each end, and the principle upon which it works is essentially that of a differential thermometer. Each bulb contains air, the two being separated by a small column of mercury, and upon the lower bulb is a heavy coating of lampblack. When the instrument is exposed to the rays of the sun the lower bulb receives more heat than the upper one (by virtue of the absorbing power of the lampblack), and thus causes the air in the lower bulb to expand more than the top, and the mercury consequently rises. This, through leading-in contacts sealed in the glass, completes an electric circuit through a register, as already described, and at minute intervals a record is made. Of course, when the sun is not shining the record is a straight line.

The rain or snow gauge is also dependent upon electricity for its operation. In one form, styled the tipping bucket gauge, a small pair of buckets is mounted upon a knife-edge, the point of support being below the centre of gravity. As the bucket is filled it tips and discharges, the other one being brought immediately under the delivering nozzle; thus a tipping backward and forward motion, and with every discharge an electric circuit is completed through the register and recorded in the usual manner. An improved form of weighing rain and snow gauge quite recently invented is considered quite an achievement of ingenuity among meteorological instruments. It works upon the principle of the balance beam and is always in equilibrium. Upon one end of the beam is a bucket, and a very few drops of water depresses the beam far enough to discharge same and also completes an electrical circuit through the recording register; the register at the same time closes another circuit through an electro-magnet, which restores the beam to equilibrium.

Each $\frac{1}{100}$ of an inch of rainfall is recorded, and an equal amount in weight of hail or snow.

Registers are made so that they may record several of these meteorological events on the same instrument, and are accordingly styled double, triple, quadruple, etc., thus utilizing one clock movement mechanism, drum, etc., for several records, which is a great advantage in that it eliminates time error corrections. Instruments may be used for simultaneously recording two different anemometers for comparison, or two rain gauges, one anemometer, rain gauge, sunshine recorder and anemoscope, etc. Only a few cells of battery are required, preferably of the closed circuit type, as gravity, depending on the distance of register from instrument, and several circuits may be connected together.

Numerous other instruments exhibited, although not depending on electricity, were very interesting, such as the barograph or recording aneroid barometer, recording the barometric pressure by means of expanding and contracting vacuum shells actuating levers attached to a pen, on drum; the thermograph, graphically recording temperatures by expansion and contraction of a glass tube containing alcohol; psychrometers, polymeters, hygrometers, etc.

Recollections of Werner Von Siemens.[*]

III.—The Stirring Events of 1848.

[Upon the uprising in Schleswig-Holstein against the Danes in 1848 Von Siemens conceived the idea of defending the harbor of Kiel by submarine mines. The Government approved of the idea whenever war should be actually declared.—Ed.]

I employed this waiting-time in making preparations. Large and particularly strong canvas-bags rendered watertight by caoutchouc were got ready, each capable of holding about five hundred-weight of powder. Further, wires insulated in all haste and exploding contrivances were prepared, and the necessary galvanic batteries procured for firing. When the departmental chief in the War Office, General von Reyher, in whose ante-room I daily waited for the decision, at last made the communication, that he had just been appointed Minister and, war having been resolved against Denmark, that he granted me the desired furlough as the first act of hostilities against Denmark, my preparations were almost completed, and on the same evening I left for Kiel.

In Altona, where great excitement prevailed, my brother-in-law Himly already awaited me; a special locomotive took us to Kiel. The news of the declaration of war by Prussia had already become known, but was still considerably doubted. My appearance in Prussian uniform was rightly taken as evidence of the longed-for fact and excited on the whole way to Kiel and in the town itself unbounded joy.

My brother-in-law in Kiel had meanwhile made all the preparations in order to proceed quickly with the laying of the mines, as the appearance of the Danish fleet was daily expected. A ship-load of powder had already arrived from Rendsburg, and a number of large casks stood ready, well calked and pitched, in order to be provisionally used instead of the still unfinished caoutchouc bags. The casks were as quickly as possible filled with powder, provided with fuses, and anchored in the rather narrow channel in front of the bathing establishment in such a way that they were buoyed twenty feet under the surface of the water. The firing-wires were carried to two covered points on the shore, and the course of the current so disposed that a mine must explode if at both points simultaneously contact was made.

At both places of observation upright rods were set up and the instruction given that contact must be made if a hostile ship took up a position in the direct line of the rods and remain made until the ship had again completely removed from the right line. If contact of both right lines were at any moment simultaneously made the ship would be exactly over the mines. By experiments with small mines and boats it was ascertained that this exploding arrangement acted with perfect certainty.

There now began a right cheery life in the fort. My citizen-troops did their duty conscientiously. On organizing the service I found to my surprise among the men members of well-known noble families of Schleswig-Holstein and respected citizens of the town of Kiel. They all however submitted implicitly to the command of a young Prussian artillery officer of their own selection. I had the ramparts cleared, the embrasures repaired, and the old cannons placed on such platforms as remained. The powder magazine was put in order and a stove erected by Kiel artisans for making the balls red hot. I was especially assisted in this work by my man Hemp, (who without orders had followed me from Berlin,) an intelligent, able fellow, who subsequently accompanied me in all my telegraphic undertakings and finally became chief engineer of the Indo-European telegraph line, which position he occupied till last year. With his help the men serving a gun were hastily trained, so that on the third day after the occupation we could essay a first shot, which announced far and wide the military occupation of Friedrichsort.

Arms, ammunition and military insignia I obtained from the ever helpful commander of the town, whose name unfortunately has escaped my memory. My corps of volunteers was recognized by the provisional government, and also received the usual pay. In the military training of the folk my before-mentioned man Hemp, whom I named chief of the artillery, again rendered me signal service. The cannons were certainly old and bad, but a short 24-pounder and a howitzer were still serviceable; the Danish blockade ship, which no longer left the harbor-roads, seemed somewhat to respect the red hot balls, which we always sent her when she came within range.

One morning we were alarmed by the announcement that three large Danish men-of-war were lying in the roads. It seemed indeed as if an attack on the fort were intended, which, considering its bad condition and equipment, would have had the chances in its favor. The weakest point of the fort was the entry gate opening on the inner harbor. The drawbridge was out of repair, the moat was dry and the ravelin protecting the entry only remained in its outlines. As meanwhile my brother-in-law Himly had partially replaced the casks temporarily employed for the mines by the indiarubber bags that had arrived from Berlin, I ordered one of these now superfluous casks to be towed to Friedrichsort, in order to be there used as fougade for the defence of the fort gate. The day before the alarm I had had a deep pit dug in the middle of the old ravelin and the cask lowered therein. As night had come on before this work was finished, the pit remained open and was guarded by a sentry. When next morning the alarm occurred, I commissioned my brother Frederick—who, as subsequently my brothers William and Charles, had followed me to Kiel and Friedrichsort—to prepare the firing communication, to enable the mine to be exploded in case of an attempted storming of the ramparts.

The ships had now really approached within range. My three serviceable cannons were manned and the oven for heating the balls in full activity. I prohibited firing, however, before the ships forced the entrance. The rest of the men I had collected in the fortress yard to distribute them and exhort them to bravery, when suddenly before the fort gate rose a vast fire sheaf. I felt a violent compression succeeded by a violent expansion of the chest; the first sensation was accompanied by the clatter of broken window panes, and the second by the elevation of the tiles of all the roofs to the height of a foot and their subsequent fall with a dreadful din.

Of course it could only be the mine, whose explosion had produced the mischief. I thought at once of my poor brother Fritz. I ran to the gate to look after him, but before I reached it he met me uninjured. He had prepared the mine, set up the battery on the *terre-plein*, connected the one igniting wire with the one pole of the battery and fastened the other to the branch of a tree to have it ready to hand, and was about to announce this when the explosion occurred, and the atmospheric pressure hurled him down from the rampart into the interior of the fort. The rather violent wind had shaken the second firing wire from the tree, causing it to fall just on the other pole of the battery and so producing the explosion.

With the sentry, who was standing on the breastwork of the ravelin when the explosion occurred, it had fared worse. I found him on the other side of the pit lying on the ground apparently dead, beside him his gun buried half barrel length in the earth bayonet forward. The powerful draught, caused by the mine exploding in the open pit, had evidently caught the man up and hurled him over the crater of the mine. Fortunately, however, he had clutched his gun convulsively, and thereby the blow in falling was mitigated. The man came again to his senses after the lapse of an hour; he bled indeed from mouth, nose and ears, and then became blue over the whole body, but was otherwise uninjured and after a few days again fit for service. The Kiel military doctor, who had hurried to Friedrichsort on the announcement of the appearance of the Danish squadron, and was crossing the drawbridge at the moment of the explosion, was more seriously injured. He was thrown with his vehicle into the rampart moat and had received a few contusions. The cook too, who was just carrying up the steps of the ground floor a bowl of soup and was thrown down by the explosion, was severely scalded.

Extremely remarkable were the mechanical effects which the explosion produced in a wide circuit. It must be considered as a shot from an open earth-formed tube with a charge of five hundred-weight of powder. In the entire fort no space of any extent remained closed. Either the atmospheric pressure had pushed in the doors or walls, or where they resisted the ensuing vacuum had burst them asunder. The window-panes even in the villages of Laboe and in Holtenau were broken. The differential pressure must in the interior of the fort have amounted to at least an atmosphere, otherwise it could not have produced such effect at so great a distance.

When I returned to the place where I had left my troop I found it deserted, and feared that the people in their first terror had dispersed and crept away. I soon however saw to my delight that they had all betaken themselves to their assigned places. They had imagined that a Danish bomb had struck and the attack had begun.

The Danish ship had however determined to proceed no further, returned to the outer roads, and soon abandoned these also with the exception of the blockade-ship. In the Copenhagen newspapers it was shortly afterwards reported that one of the submarine mines with which the harbor of Kiel was paved had accidentally exploded and destroyed the fort. Indeed the view from the ships must have been rather astonishing. The red tiles of all the buildings of the fort protruded over the low ramparts, and rendered them particularly conspicuous. Immediately after the explosion however all the tiles had fallen down, and no houses were any longer visible.

---

[*] Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

That the Danes had acquired considerable respect for the mines is proved by the fact that in spite of the notorious weakness of the artillery defence of the Kiel harbor during both Schleswig-Holstein wars no Danish ship ventured into it. Although these first submarine mines never came into action they none the less accordingly played a very important part, I may therefore with justice complain that later military writers have completely ignored this first harbor defence by the help of submarine mines, carried out in view of the whole world and at the time much talked about. Even German military writers have subsequently ascribed the invention to Professor Jacobi in St. Petersburg, although his experiments at Kronstadt were carried out many years later, and he himself never dreamt of disputing my claim to the invention and its first employment in war.

When after conclusion of peace the mines were fished up and lifted, the powder in the caoutchouc bags was found still dry as dust, despite the two years soaking in sea water. It is thus not doubtful that, had occasion offered, the mines would have done their duty.

(To be continued.)

Modern Uses of Electricity—IV.

ELECTRIC LIGHTING.

This was the subject of Prof. Cross's fourth lecture in his course on "Modern Uses of Electricity," in Huntington Hall, Boston, November 13, and the lecturer in entering upon his address said that in a previous lecture he had alluded to a modification that had taken place in the building of dynamos, which modification meant that much more iron was now used in their make than formerly and less copper. The idea of a magnetic circuit with iron in the field had been early wrought out by Hopkinson in England, and was now very general in practice. At the same time it was difficult to lay down any hard and fast rules for making dynamos. It was about nine years ago since the change was first made; now the art has reached the point where it would appear that no further great change was possible.

Michael Faraday was the first to set forth the fact that if you have a current passing through a coil of wire there is an E. M. F. or lines of electric flow. Faraday had an idea also that different substances possess different resistances to the flow of such magnetic lines of force. That is, if we compare air with iron when the magnetic field is in air strongly excited the proportion is about 10,000 to 1.

Reluctance in the magnetic field is equal to the resistance in the electrical field, whereas for a steady current the resistance of a substance is a constant. That, however, is not true of the magnetic flow. If we multiply the magnetic flow by the same number of turns and the flow of current, it will be found that the iron produces saturation. If you double the magnetic lines of force you increase the strength 10 per cent. or 15 per cent. according to the iron or strength of the field.

Certain substances, as for instance brass, do not have any such change in their reluctance when their magnetic force is increased. Bearing that in mind, supposing we had a coil through which a current is flowing. You put a bar through it and the lines of force will flow round from one point to the other. The closer the poles are brought together the less will be the reluctance of magnetism. Increasing the section of a coil reduces the reluctance and increases the magnetic lines of force. This principle is what has led to the changes in the manufacture of dynamos.

The machines thus far discussed are what are called bi-polar machines, and which have no more than two poles. There is no reason why two poles should be the limit, for it is possible to have four or more poles. By using suitable commutators as many as four brushes may be used. The Gramme ring may be considered as two batteries coupled together.

A large number of different types of dynamos were then shown on a screen, the lecturer expatiating at length on their distinctive features as they were exhibited.

Proceeding next to a consideration of the electric arc, Professor Cross said that the arc light was the most brilliant artificial light known. Fifty years ago it was a rarity, to-day it was to be seen in all our streets. In considering its peculiar characteristics, it were well to bear in mind that an arc could not be produced except with a current of 40 volts or more potential, generally it was 60 volts. It was possible to produce an arc of immense candle power—those in general use were rated as of 2,000 C. P., though the term C. P. was really only a nominal term. Under varying conditions the brilliancy of an arc light varied very materially. In an arc light, as would be seen by reference to the spectra of an arc light and of the sun, there was more color than in the latter luminary. The reflection of an arc light was thrown upon a screen, and the varied brilliant phenomena, the crackling noise, the flying particles of incandescent carbon, the difference in form of the opposing ends of the carbon pencils, together with the rich colors in the atmosphere surrounding and in the interior of the arc were shown and fully explained, to the delight of the large and attentive audience.

The Westinghouse Company Wins.

The contract for ninety car equipments for the big Consolidated Road of Cleveland has been awarded as follows: Westinghouse Company, 50; Steel Motor Company, 20; General Electric Company, 20.

This is a decided victory for the Westinghouse Company, this system having been among the oldest customers of the General Electric and Edison Companies.

The fight for the contract was closely contested, Capt. Eugene Griffen looking out for the General Electric interests, and Mr. Lemuel Bannister appearing for the Westinghouse Company.

A Stationary Detective.

Electricity Applied to Thief-Catching.

For some time the firm of Foster, Stevens & Company, Grand Rapids, Mich., has been a loser by persistent robbery. A few days ago a detective arranged a photographer's camera focused on the cash-drawer. An electric connection was fitted to the drawer and the camera so that when the drawer was opened the shutter of the camera would be operated and the same instant a calcium-light would be flashed. The robbers when they pulled out the till were startled by the flashlight, but as no demonstration followed, they finished their work. The suspects were arrested, and when confronted by the photograph taken during the flashlight exposure, they broke down and made a full confession.

An Automatic Time Recorder.

An automatic time recorder for use in horse races, bicycle races, etc., has been invented by Mr. Alfred Bartlett, of New Zealand. The mechanism is enclosed in a cylindrical case, on the top of which is fixed a horizotnal dial, which is divided into 60 seconds, and each second is subdivided into fifths, while a smaller dial registers the minutes. An outer circle has a number of stops, numbered from 1 to 60, and is brought into use in starting for events in which the time system of handicapping is required. In connection with the "clocking" machine is an electric battery with bell attachments, which is fixed at the starting point while the time recorder is placed at the winning post. The mechanism for starting time handicapped events is brought into operation by pressing down the button on the outer rim of the dial, in accordance with the time adjustments fixed for the starters, and, starting from zero, the times at which the other horses handicapped in the race leave the mark are accentuated by a bell, so that no mistake can occur in dispatching the field just as the handicapper had arranged. The seconds hand, which registers the time on the large dial, is carried on a cylinder about 3 inches in diameter and of a similar depth. The outer surface of the cylinder is vertically divided into 12 parts, corresponding with which, on the inner surface of the cavity in which it revolves, are a dozen inked points. The circumference of the cylinder is divided into seconds and fifths, and the aforementioned inked points are electrically connected with the tapes at the winning end of the running tracks. The signal for starting is given by a loud-sounding electric bell at the starting post, and simultaneously the recording machine at the other end is brought into operation. The tapes at the winning end of the tracks are electrically connected with the inked points, and the instant that the connection is broken the inked point registers on the corresponding section of the revolving cylinder the time occupied in covering the ground, as well as the relative positions of each competitor as he breasts the tape.

Good Luck for Mr. McDonald.

The bonds of the New Orleans Traction Company, $6,000,000, in which company Mr. R. T. McDonald was largely interested, have been taken by New Orleans capitalists. The arrangement was consummated by the banking house of Seligman & Co. on the 4th inst.

The system will now be pushed to completion with electrical equipment throughout.

It looks to a man up a tree as if the new railway motor of the Fort Wayne Company might possibly make its debut in actual service in the city of New Orleans, as Mr. McDonald still retains a large interest in the Traction Company.

Storage Batteries for Central Stations.

The report on this subject recently read before the Convention of the American Street Railway Association seems to have been productive of good results, as three concerns have already announced their intention of putting large central station batteries on the market.

Mr. Malloux, the author of the report, says that in one case he was shown the plates in process of manufacture. The information obtained by him since the paper was read seems to show quite conclusively—

1st. That the cost of large central station batteries will not exceed $35.00 per kilowatt hour, set up, in most cases, and for smaller sizes will not exceed $50.00 per kilowatt hour.

2d. That the cost of maintenance will not exceed 10 per cent. of the initial cost.

3d. That the rate factor can be safely based on three hour discharge, or even less, in most cases.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:
UNITED STATES, - - - - - $2.50
IN CLUBS OF FIVE OR MORE, - - - - $2.00
FOREIGN COUNTRIES, - - - - - - $4.50
SINGLE COPIES, - - - - - - $ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

The Niagara Power Plant.

Elsewhere will be found in part a paper by Prof. Geo. Forbes, recently read before the English Institution of Electrical Engineers, in which he lays before the public in considerable detail the plans of the Niagara undertaking and explains the reasons which led to the adoption of a number of new departures in the equipment of the plant.

The most noticeable of these is the unusually low frequency of the alternations, and as the figure chosen is too small for ordinary lighting work, it has been the cause of considerable surprise among electricians. From Prof. Forbes's paper it appears that most, if not all, of the current from this plant is expected to be used for running motors, for which purpose the reduction in frequency adds considerably to the efficiency. It is also pointed out that there will be but comparatively little business lost by designing the plant exclusively for the transmission of power, as almost all the arc lighting being run with direct currents a transformation would be needed, and for incandescent lighting the plan would generally be to supply the present stations with motors to replace their steam engines. In this view of the matter theory seems to dictate a very low frequency, but it appears after all that the selection of twenty-five periods per second is to some extent experimental, as we believe no practical trial at this figure has yet been made. The greatest objection to this is probably the increase in the cost of transformers. This is partly counterbalanced, however, by the proportionally large size of the transformers which will be chiefly used in this plant, which largely reduces the cost per horse power, and it is also to be noticed that by reducing the frequency the induction may be increased, so that the size of the transformers actually varies by less than half of the proportion between different frequencies.

The adoption of a multiphase system seems in the present state of the art to be the only solution of the general transmission of power to the distances and for the multifarious purposes contemplated in this project, and the two phase system has been found to involve more expense in construction than the three phase, and is easier to regulate and operate.

This system will also introduce a certain amount of uncertainty, as on this side of the water little has been done in this field. There seems to be but little doubt of the possibility of constructing efficient two phase motors suitable for this current, but we certainly have none at present on the market, as no suitable current supply for them has existed.

Many of the purposes mentioned by Prof. Forbes for which the Niagara power plant will supply current are those in which a direct current will be essential. Among these are street railway power, power for canal boats on the Erie Canal, and current for the electrical reduction of aluminium. In these cases it appears that the methods of transforming remain to be decided upon, as the paper only states in regard to this that "some sort of commutator or motor transformer will be desirable." Commutators of this sort still remain to prove their usefulness, and while motor transformers are entirely practicable for this purpose, the installing of these machines means a pretty heavy expense, and the efficiency of the combination leaves considerable to be desired, as except for the loss in the belt it is about the same as utilizing the two phase current to drive a motor which in turn drives a dynamo to generate the current desired. If a large part of the power is to be applied in this way, the losses in the transformations must amount to considerable.

Another important class of customers mentioned is a class of mills some of which operate continuously day and night throughout the year, and for the latter synchronous motors are well adapted. Where starting and stopping occur even only in the morning and at night some trouble may be expected with this class of machines, especially if this occurs when they are loaded. In fact, in the absence of some device for this purpose not yet known, this trouble would be fatal to the use of synchronous motors in many cases. In a few places where they have been used on a large scale the conditions have permitted the machines to be started without load, and even in these places auxiliary self-starting motors have been necessary for putting the large machines in step with the generators. Where the synchronizing motors are feasible, however, they operate with excellent efficiency.

The electromotive force adopted in the first machines is 2,500 volts, although 20,000 volts is the figure to which the current is to be raised by transformers for distribution. In Prof. Forbes's opinion 20,000 volts is as easily produced at the generator as at the transformer, but as none of the American manufacturers could be persuaded to this view of the case, step-up transformers will be used on the first machines installed, although it appears to be the plan to generate the full pressure at the dynamos eventually. While we have no experience in central station work at anything like this pressure, it certainly must make the running of the station a rather uncomfortable job, and as in this particular case the cost of fuel hardly enters into the calculations the loss in efficiency due to the use of step-up transformers would not be very serious and could be compensated for by the use of a little more water if necessary.

The idea of having a uniform system, that is, having interchangeable dynamos all at the same pressure, will undoubtedly prove an advantage in the end as it is the only way by which the full capacity of the plant may be always utilized, and the management of the station will be thereby much simplified. The use of special dynamos for the different kinds of current required would limit the capacity of the station considerably, as, for example, the machines devoted to arc lighting would be only in use at night and could be turned to very little account during the daytime.

The details of the plant appear to have been studied out with the greatest care, and these remarks are not intended as criticisms, but simply to point out that much of the work will be experimental. Its successful completion, for which we confidently look, will therefore mark an important advance in the science of electrical power transmission.

……

THE Directors of the General Electric Company have officially announced the suspension of dividends on the $4,251,900 of 7 per cent. preferred stock. This is hardly news to the readers of ELECTRICITY, who were told two weeks ago that this action had been decided upon. We understand now that some of the preferred stockholders are going to make trouble, claiming that the preferred stock should come before the debenture bonds in the matter of dividends.

……

MR. E. A. KILBOURNE has been arrested on charges preferred by Mr. B. E. Sunny, charging the former with an attempt at blackmail. We trust that Mr. Sunny may clear himself of the suspicion of fraud; he cannot clear himself of the *fact* of incompetence and stupidity. A million and three quarters of bad paper in the Chicago office for one year is an unanswerable argument.

……

MR. SAMUEL INSULL has not been regarded as a humorist, and we don't know that he is one. But it is certain sure that he offered $20,000 less than shop cost for the big multipolar Edison machine which was in the World's Fair service plant, and that now the white elephant is the property of the Chicago Edison Company. Perhaps Mr. Insull's former office boy is the humorist.

……

ELECTRICITY called attention a few weeks ago to the fact that the Fort Wayne Electric Company had everything to gain and nothing to lose by severing its connection with the General Electric Company. We are pleased therefore to report that the sales of the Fort Wayne Company for November last were a little more than double what they were for the same month of last year.

……

SOME of our readers may have noticed an advertisement in the daily papers offering a large salary to an accountant of peculiar ability for three or four weeks' work. It seems that with all the talent on hand Mr. Coffin is unable to find any one who can prepare a statement showing that the General Electric Company is solvent.

……

WE HAVE not on hand a verbatim copy of the letter from Mr. C. H. Coster which was read before the General Electric directors' meeting three weeks ago, but we would like to have. We feel confident that the many friends and admirers of Mr. B. E. Sunny would count it interesting reading.

……

THE stockholders of the General Electric Company are the most complacent people who have been swindled by wholesale in the history of Wall Street bubbles.

A Slight Exaggeration.

(From the Evening Advertiser.)

A Trust before a court has as little show as a cat before a jury of dogs.

Northwest General Electric Co.

One of Mr. Coffin's Paper Companies which Can be Juggled with no Longer.

In Liquidation, and Nothing Left for Stockholders.

The official announcement that the Northwest General Electric Company is going into liquidation has created consternation in Boston, where the preferred stock was largely sold, but the matter has not received the attention in New York which its importance warrants.

True, the amount of money involved was not large, and a great many of the General Electric stockholders perhaps have never heard of the Northwest General Electric Company.

ELECTRICITY, however, had heard of it, examined it, and reported upon it April 19, 1893, as follows: "Northwest General Electric, T.-H. Electric Light, and T.-H. Motor Company, *no value;* they are simply selling agencies, showing shortages which are made up by the General Electric Company."

The liquidation of the company, from which the stockholders realized nothing, is instructive when viewed in the light which history sheds over all of Mr. Coffin's many schemes.

We present below two statements, prepared about two years ago by Uncle Ellery Garfield, who had a limited number of copies made by his confidential typewriter, and which were distributed to the "chosen few who were permitted to invest in the preferred stock."

It is presumed that the "cash on hand June 1, $4,474,94," gave warning that something must be done, and that for the next six months all hands, especially Mr. Coffin, had in view a statement which would sell stock. Thus the cash had increased from less than enough to pay a month's salaries to $126,579.95 by December 1, when the preferred was offered.

NORTHWEST THOMSON-HOUSTON ELECTRIC CO.

Financial Statements, June 1 and Dec. 1, 1891.

ASSETS.

	June 1.	Dec. 1.
Franchise	$110,000.00	$110,000.00

NORTHWEST THOMSON-HOUSTON ELECTRIC CO.

STATEMENT.

Profit and Loss Account, June 1 to Dec. 1, 1891.

Gross profit on merchandise account		$89,523.34
Gross profit on construction		38,939.76
Total gross profits June 1 to Dec. 1, 1891		$128,463.10
Less expense accounts		75,357.92
Net profit to St. Paul, June 1 to Dec. 1		$53,105.18
Net profit, Portland		29,423.79
Net profit, Helena		7,279.49
Total net profit, six months, from June 1 to Dec. 1, 1891		$89,808.46
Surplus, Dec. 1, 1891	$190,409.34	
Surplus, June 1, 1891	100,600.88	$89,808.46

Accompanying the above was a circular, which made it plain to all that N. W. T.-H. was a gilt-edged investment. We extract a few samples which are truly Coffinesque:

"The secretary of the Thomson-Houston Company with an expert auditor has lately made a critical examination of the assets, scaling them down to an extremely low and conservative basis. After deducting about $250,000 from the inventory the company has a surplus of over $100,000 worth, besides having paid up to close of 1890 quartely dividends amounting to eight per cent. annually on the outstanding stock from the time of the organization of the company.

"The company has no bonded debt, and none can be created except by the vote of the preferred and common shareholders.

"An annual charge of but $60,000 is required to pay dividends upon the preferred stock.

"This stock is offered with the belief that it is an exceptionally safe and carefully protected security, issued as it is on the basis of less than one-half the capital actually invested, and being surrounded with safeguards that will insure regular and permanent dividends."

The safeguards were manifestly not strong enough.

Captious critics who are interested in the subject might well inquire if these statements were true and correct at the time they were issued, or were they deliberately falsified to hoodwink Boston investors.

This statement showed an increase in surplus in the six months from June 1 to December 1, 1891, of nearly $90,000, and reported assets to cover all liabilities, including $1,258,600 of stock. In twenty-three months' time the surplus is gone and the capital stock is wiped out.

The General Electric Company cannot make as complete and noiseless a collapse as the Northwest General Electric Company, because it owns property, whereas the latter company owned nothing. But the last statement of the General Electric Company was as false as the one printed above, and was falsified for the same purpose—the unloading of worthless securities.

Thus credits throughout the entire range of electrical investments are smirched and thrown under suspicion, and the robbers still ply their trade.

ELECTRICITY is not surprised and will not be when every one of Mr. Coffin's paper houses fall in the same manner.

SOCIETY NEWS.

Meeting of the New York Electrical Society.

A regular meeting of the Society was held on Wednesday evening last at Columbia College, and the lecture room was far too small to accommodate the large audience which assembled to hear the speakers that were announced. It was found before the close of the evening that it would be impossible to complete the programme laid out, as about half the speakers occupied the whole evening, and it was voted to continue the subjects left over at an adjourned meeting.

"Electricity at the World's Fair, and its Lessons," was the subject of the evening, and Mr. Mailloux, who was elected chairman, was the first speaker, describing the exhibits of storage batteries at the Fair. After an interesting resumé of all the batteries exhibited, and the methods of charging, etc., Mr. Mailloux introduced Dr. Emery, who spoke on the subject of steam engines, and illustrated his remarks with a large number of lantern slides. The Corliss, Galloway and Ball compound engines were described, and the Buckeye compound engine was specially noticed for its ability to take from no load to full load with almost perfect regulation. The Edison vertical engine, with two direct connected 800 K. W. dynamos, was shown, but was not tested at the Fair. The Westinghouse 1,000 H. P. and a Siemens & Halske engine were next shown, and the latter was noticeable for its beautiful finish, and smooth, noiseless operation. The

Lake Erie engine, the Willans engine and the steam turbine were also described.

The next speaker was Prof. Crocker, who spoke of the Electrical Congress. He said that there had been but five Electrical Congresses ever held, and of these only two had been official, that is, attended by the official delegates from foreign nations. In every respect, except merely business matters, Prof. Crocker considers the last congress very satisfactory. The results achieved were valuable in three respects particularly. First, the final names and values of the electrical units were established; second, the adoption of the henry is an important acknowledgment of the work of an American by foreigners, by whom the name was proposed and seconded; and third, the important papers which were read and the eminence of their authors.

Prof. Crocker said that while it had been suggested that there could arise no further necessity for another congress in the future, he thought that the subjects of magnetic units, standard of light, and international nomenclature still remained for the discussion of future congresses.

Mr. Nicola Tesla then followed with some remarks on the oscillatory engines which formed the subject of his lecture before the Electrical Congress last summer. In that address, Mr. Tesla said, he had confined his remarks to the purely scientific side of the subject, and from the comments which had since come to his ears he was convinced that he had not been fully understood. In his first experiments in this line he employed a steel spring to regulate the vibrations of the piston and armature, which must be perfectly constant. Next an air spring was tried, and later an air spring connected with the outside air and surrounded with boiling water to keep the temperature rigorously constant.

The reciprocating mechanism has the advantage of making all the wire active as in a transformer, avoids loss by friction and reduces the weight of the machinery. For the latter it is of great importance to use very high pressures.

Mr. Tesla thinks that the development of the principle on which these machines are constructed will furnish a means of producing probably twice as much electricity from coal as at present.

Mr. J. J. Carty spoke very briefly of the Telephone, the most interesting exhibit of which was the New York and Chicago line. There was nothing particularly new in this branch of electricity, Mr. Carty said, and the improvements made recently were in the direction of perfecting the well known inventions. The most important change which has been made in the system is that from series to multiple working, the latter now being general.

Mr. James Hamblet made the closing address of the evening, speaking on electric clocks. He stated that only a few days ago the first decade of electric time had been completed. Over two hundred electric clocks of various kinds had been exhibited at the Fair. The first invention of this kind was in 1851. In the first clocks the hands were propelled directly by electricity, later the mechanism was wound every hour, then a method was invented for correcting the hands every hour by means of a standard clock.

Another class of clocks was the large tower clock in the Manufactures Building at the Fair, to which the current was sent in impulses, one each minute, and the hands moved intermittently. Besides these there are a number of electric clocks built to perform special functions, as chiming clocks, signal transmitting clocks, programme clocks, etc.

The meeting closed with the exhibition of a large number of lantern slides of views of the Fair which were announced by Dr. Emery.

The Electrical Transmission of Power from Niagara Falls.

BY PROF. GEO. FORBES.*

RELATIVE ADVANTAGES OF DIRECT AND ALTERNATING CURRENTS.

A few years ago it would have been considered necessary to devote a considerable amount of space to the discussion of the relative merits of direct and alternating currents. During the last two years, however, opinions have advanced so steadily in the direction of preferring the alternating current for the transfer of power to any considerable distance that it is not necessary to give much time to this question. One of the chief difficulties in connection with using the direct current is that it is necessary, for getting the best results, to connect a number of dynamos in series, and also to put the motors at the receiving end in series with each other. This involves the insulation of each dynamo and motor from the earth—a requirement which can in some cases be attained, but which in a general system of distribution is apt to be attended with difficulty, and perhaps with danger. The best case of the kind which has been put in practice is that of Genoa, and we gave it the most serious attention, but came to the conclusion that, for our purpose, it was undesirable. The facility which the stationary transformers used with the alternating current give for varying the pressure according to the requirements of economy or safety is one great feature in favor of the alternating current. The question was considered in all its bearings with the utmost care, and it was not until the month of May, 1893, that the board of directors passed the resolution to adopt the alternating current, both for their distant transmission and also for the works nearer to the power-house. It was proposed, indeed, by some manufacturers to distribute the current within a radius of a mile or two at 700 or 800 volts, and one firm proposed to do this by means of a direct current. Had this plan been accepted, we should have arrived at the surprising result that by using the continuous current at 700 volts within a mile or two, and high pressure alternating current for more distant places, it would have cost more to produce a horse power per annum at Niagara Falls than at Buffalo.

The argument that seemed to me the most important in favor of using the direct current was that motors for this purpose have been made in much larger quantities than alternators, and that it would be seldom necessary to build special types of machines to act as motors. This advantage seemed of great importance until I realized the value of a low frequency used with the alternating current. So soon as we reduce the frequency low enough, we are able to alter a direct current motor into a synchronizing alternating motor by the simple addition of a couple of rings placed on the commutator and electrically connected with opposite bars of the commutator, and a brush rubbing on each of these collecting rings. I also took into consideration the question of the possibility of storing up energy in storage batteries during the night time, when, of course, the demands on our plant would be least, and giving it off during the day time; but at the present time the cost of the batteries would not repay work in this direction, and it would be cheaper to make another tunnel, with wheel pits, turbines and all the paraphernalia required to generate current, than to go to the expense of putting down the large amount of lead which is required for these batteries. With the alternating current we have the choice of a considerable number of motors of different types. We have the synchronizing motor, the series wound motor with laminated field and commutator, the multiphase motors, which attracted so much attention at the Frankfort Exhibition of 1891, and a host of single phase motors which have been placed on the market because of the high frequency which has been prevalent and with which they were not altogether satisfied. These motors become immediately available if we use a lower frequency. The generation of an alternating current also permits of the use of a commutator, or rectifier, with direct current motors.

NUMBER OF PHASES.

Assuming now that it is generally agreed that the alternating current must be adopted, not only for distant transmission but also for the nearer work, the next point to consider is the number of phases—whether the current should be generated in a single phase, in two phases, or in three phases. The possibility, too, of using even a greater number of phases was also considered, but it did not seem to possess advantages.

As already stated, there are many motors which are suitable for use with a single phase at low frequency and which starts without assistance. In the workshops of nearly all the most able electricians which I have visited in the course of the last year or two, I have found such motors built upon different plans, and nearly all of them seemed to work fairly well, and promise to be very efficient at low frequency.

For all heavy work which is going on, constantly without stopping the machinery, no motor could be more suitable than the synchronizing alternator on a single phase, and its speed is as regular as that of the turbine which is developing the power. It seems, however, that even if single phase motors are going to be adopted, it would be best for the generator to have two phases, because in this way we get a larger output for the same size and price of machine; the circuits may be perfectly independent and supply separate motors. Also, the two phase system makes the rectification or commutation of the current more easy to use it for street railways, electro-metallurgy, etc. Again, multiphase motors have the great advantage that they have been considerably utilized already, and even in small sizes have a fairly good efficiency.

With regard to the relative merits of two and three phases several claims that cannot be supported have been put forward in favor of the latter. First, it is claimed that the saving in the copper on the line is 25 per cent. over a one phase system, and 25 or 18 per cent. over a two phase system, according as four or three wires are used for the purpose. I investigated this matter carefully, and arrived at the conclusion that this was not the case, and that the three phase system had no advantage in this respect over a two phase system with three wires. Second, it is claimed that there is a greater simplicity of wiring with three phases than with two phases; but this advantage disappears when we remember that the two phase system can be used with only three wires, although this is not a plan which I would recommend. Third, it is claimed that any pair of the three wires may be used for a distribution of lighting. This is not the case. A two phase system, where the circuits are completely independent, is much more suitable for the purpose, and maintains the lights at a more constant electric pressure. Fourth, it is claimed that there is a smoother starting and rotating effort with the three phase than with the two phase system. This was originally claimed on theoretical reasons only by Dobrowolski, but everyone who has used the type of two or three phase motors made by the Oerlikon Company, by C. E. L. Brown, and by the Allgemeine Elektricitats Gesellschaft, of Berlin, and others, is convinced that this advantage, which seems probable enough, is purely theoretical; it is not confirmed by actual practice, and, moreover, when the fact is known, the theoretical reason is pretty evident.

---

* From a paper read before the Institution of Electrical Engineers, England.

No other claims in favor of the three phase system over the two phase have ever to my knowledge been advanced; and, as shown above, a very full consideration of these claims does not tell in favor of the three phase.

I will now point out what seemed to me great objections against the three phases, due to the fact that the three conductors are all interconnected. First, it introduces trouble in maintaining the efficient working of the line, and in testing it, so that a higher type of electrician would be required to make these tests, and even he would have greater difficulty in finding the faults and correcting them. Secondly, when the three circuits are unequally loaded the electric pressure varies considerably. These difficulties have been thoroughly appreciated by workers in this line. When an interconnected set of circuits such as the three phase system employs is used, it is found that when the circuits are unequally loaded there are great variations in the electric pressure, and the following tests were made at my request to illustrate this. The three circuits are called A, B and C. The average electric pressure of the three branches at the terminals of the secondaries were maintained constant. A resistance tending to reduce the electric pressure at the lamps 5·3 per cent was introduced into each branch. Both the primaries and the secondaries were connected as represented by the form of the letter Y. By varying the connections in different ways, some slight variations were possible; but this general fact remained that when A is loaded and B and C are not loaded, the pressure of A is less than that of C, and that of C is less than that of B, and the difference may be 12 or 13 per cent.; and when A and B are loaded and C is not loaded, the pressure of A is less than that of B, and that of B is less than that of C. The variations here shown in the pressure of two equally loaded circuits is probably due to the armature reactions, and would be found in a two phase system also; but the rest of the variation is due to the interconnection of the three circuits, and is an obvious defect of the three phase system. In order to get over this difficulty, the Oerlikon Company proposed to devote only one circuit to lighting purposes, which shall be maintained at constant pressure, using the other two circuits for power purposes, where constancy of pressure is not so important. In some cases this would be a suitable method of working, but it was not considered satisfactory for the work at Niagara Falls. Having considered these points, the board of directors of the Cataract Construction Company, at their meeting in May, 1893, determined to reject the three phase system, leaving the single phase and the two phase available.

Conditions.	Volts at terminals of lamp mains.				Difference between maximum and minimum volts.

FREQUENCY OF ALTERNATIONS.

I wish now to say some words on a question which has absorbed my most serious attention, especially since I have been acting for the Cataract Construction Company, and this relates to the frequency of the alternating current. In America a frequency has generally been adopted of 133 complete periods per second for lighting purposes. This was done with the object of reducing the cost of transformers, which were supplied to each separate house, and consequently were always of small size, and therefore expensive. The selection was also approved because American engineers working with alternating currents have generally put forward the view that parallel work is not desirable, and the fact that parallel working is more difficult at high frequency, which is one of the principal objections to high frequency, has not been seriously considered in America. In Europe the usual frequencies are from 70 to 100 periods per second, but a notable exception exists in the case of Messrs. Ganz & Company of Budapest, who have adopted 42 periods per second. Some years ago I unwittingly did Messrs. Ganz the injustice to say that I thought it probable that they had adopted this frequency because it suited their particular type of machinery and speed of running. I have it in writing from them, and I am thoroughly convinced of the truth of it, that their reason in adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working. Of course, it is a matter of common knowledge that parallel working is assisted by lowering the frequency.

With the large units which will be employed in connection with the Niagara Falls scheme, the cost of the transformers is very much diminished; and this does not become so important a matter as it does when all the transformers are of small size—under 10 H. P., as is usual in electric lighting in America. Moreover, although with lower frequency the transformers must be increased in size, the increased cost is not in proportion to the lowering in frequency, because we can use a higher induction. Mr. Steinmetz has shown that the loss due to hysteresis varies as the induction raised to the power 1·6, and it is loss which must be kept constant when we vary the frequency. I deduce from this law the fact that in any transformer, if the hysteresis loss is kept constant, its power of doing work varies in proportion to the frequency raised to the power 0·4 (but it is probably unwise to increase the induction so much as to saturate the iron). It follows that when we double the frequency we get out of the same transformer 132 units of work instead of 100. If the frequency were quadrupled, we should get 174 units instead of 100. I have been informed by Mr. William Stanley, Jr., of Pittsfield, Mass., that without the use of theory, but simply working from his experience in manufacturing and testing transformers, he obtains almost identically the same law; and I have got independent practical testimony in the same direction from other manufacturers. It appears, then, that there can be no doubt that in lowering the frequency we are not proportionally increasing the cost; but at the same time it must be realized that the cost of transformers is to a certain extent increased by lowering the frequency. If the frequency be reduced to one-half, the cost is increased about 50 per cent. The lowest price which has been quoted for large transformers is $3.52 per horse-power, at a frequency of 42 periods per second. In halving the frequency the extra cost would therefore only be $1.76 per horse-power. It becomes, then, a matter of enquiry whether the benefits to be derived by lowering the frequency in such a proportion would compensate for the extra expenditure as indicated. I am thoroughly convinced that the gain is far in excess of this amount. I shall have occasion to discuss the superior efficiency of motors at low frequency; and in most types of motors I think it safe to say that in passing from 42 periods to 21 periods, or varying the frequency in that proportion, we have a gain of at least 3 per cent. in the efficiency of the motors. Neglecting altogether the increased value of the motors from this cause, there is 3 per cent. more power at our disposal, which, at only $10 per horse-power per annum, would amount to 30 cents per annum, or, capitalized at 5 per cent., represents an increased value of $6 per horse power of the plant, against which we have the increased cost of transformers—only $1.76. It appears, then, pretty certain that, from a purely economical consideration of the question, a lower frequency than any which has hitherto been adopted is advantageous.

With regard to the lowest limits at which we can work, since our turbines have been designed to revolve at 250 revolutions per minute, a two-poled dynamo—if such could be satisfactorily constructed—would give a frequency of 4⅙ periods per second, and none of the synchronizing or polyphase motors employed at different factories could run at a higher speed than 250 revolutions. I am not sure that it is desirable that any motors should run at a higher speed than this, but in the few cases where this might be desirable the use of belts would be quite natural in order to give the higher speed. With a four-poled machine we would have a choice of speeds at 500 revolutions, 250 revolutions, and any sub-multiple of these speeds; for by increasing the number of poles in the motor the speed of the motor can be reduced as much as we please. With eight poles in the generator, the maximum speed is 1,000 revolutions per minute, which is as high a speed as would generally be desired in connection with the factories supplied from Niagara Falls. This frequency is 16⅔ periods per second, and after considering the three points—namely, cost of transformers, speed of synchronizing motors, and convenience in the design of the generators—I came to the conclusion that, so far as motive power was concerned, this is the frequency which would be most favorable for use at Niagara Falls.

Another indirect advantage of using a low frequency is of a very practical nature, and lies in the fact that the ordinary continuous current dynamos of any size that are made may be used as synchronizing motors by means of rings attached to the commutator bars in the manner which has been above described. This method of altering and working a direct-current motor so as to make it suitable for an alternating current of low frequency has long been known to electricians, but the attention of those who are not experts was forcibly directed to it by the machines shown by Mr. Schuckert and others at the Frankfort Exhibition in 1891. Owing to this fact, it would be possible for any manufacturer connected with our supply station to procure a motor of low frequency of any moderate power he might require at a day's notice, and this is not true of any other alternating motor, nor is it true of a higher frequency.

But the most obvious advantage of low frequency is the improved efficiency of motors. I have arrived at this conclusion from my own observations, but I find it confirmed collaterally. With synchronizing motors, of course, the fact has long been thoroughly established that the performance is very much improved by using low frequencies. Again, those who have used the motors with rotating field of the two phase or three phase types have all been obliged to reduce the frequency of the current to get the best results. In this connection I am pleased to be able to show a diagram giving some tests which were made for me of a three phase motor at 41 complete periods per second, and at 56 periods per second.

It will be noticed that at 56 periods the maximum efficiency is given when the output is 17 H. P. It is then 85 per cent., and the efficiency 7t 41 periods per second at the same output is 8a per cent. But it will be noticed that the efficiency at the latter frequency goes on increasing until the output of the machine is 19½ H. P., when the efficiency rises to nearly 88 per cent. Thus, by lowering the frequency from 56 to 41 periods per second, not only had the output of the motor been increased 15 per cent., but the efficiency had also been increased 3 per cent. It is also found—which is a matter of the utmost importance—that in every self-starting alternating motor, whether multiphase or otherwise, the effort at starting is increased by lowering the frequency.

Again, I find that the ordinary direct current motor with a laminated field works extremely well with low frequency; even without lamination of the field it works, though not well. I have consulted nearly every electrician of experience in this direction whom I have met during the last year or two, either in Europe or America, on this point, and they generally agree with me that the facilities of working motors of whatever kind are very much greater with a low frequency. Last year, being aware that Prof. Anthony had experimented considerably in the direction of series-wound motors with laminated field, I asked him his opinion, and he expressed himself as follows:

"In reply to yours of August 30, I have built two or three continuous-current machines with laminated fields to run with alternating currents, and have succeeded in running motors of about ⅛ H. P. directly from the Westinghouse converter, where the frequency is some 130 per second. Such small machines run very nicely where the alternations do not exceed 25 per second. In fact, so far as I have tested, they seem to give an output fully equal to what they will with continuous current. Of course, with high frequencies the self-induction of the field is against their working, but at eight per second I should say that large motors could be run with perfect success."

I wish to repeat that, from what I have seen in the workshops of all advanced electricians in the last year or two, I am confident that in the near future single phase alternating current motors, self-starting on full load, will be largely used; and there is not the slightest doubt that all of these work far better with low frequencies. In fact, as Mr. Brush once said to me when I was discussing this matter with him, "Really, your best plan would be to lower the frequency so much that you get a direct current."

Whilst speaking of low frequency in relation to motors, I must say that I have much greater hopes of obtaining a good commutating device with a low frequency than with a high one; and I will also state that I have great hopes of important advantages coming to us from the invention of such a commutating appliance which will enable us to furnish street railway companies, electro-metallurgical works and other consumers with the direct current without the use of any heavy revolving machinery at the transforming station.

I am not sure that it ought not to be said that the greatest advantage of low frequency is in connection with the conductors used for transmission, and in the parts of the apparatus that require high insulation. When a high frequency is used there are certain difficulties which are well known. The first of these has been strongly urged by Lord Kelvin—namely, that when using large conductors an alternating current of high frequency tends to confine itself to the outside of the conductor, thus increasing the total resistance. Attention was first generally directed to this subject by the presidential address of Prof. Hughes to this Institution. A second difficulty is that with high frequency the impedance of the line due to the magnetic field formed between the go and return wires may amount to a very sensible quantity. Attention has been drawn to these matters by Mr. A. E. Kennelly, and his paper* on the subject should be carefully studied. Then, again, with high frequency there is a greater tendency to discharge from an electrified conductor into the air. This means that the insulating of a bare conductor is more difficult with a high than with a low frequency. Lodge and others have made this very manifest with exceptionally high frequencies, but the truth of the statement is well known by those who have experimented even with low frequencies. Another trouble is that, whenever it is necessary to use solid insulation, a current of high frequency has a greater tendency to injure the insulation. Mr. Tesla has shown and explained so clearly the rapid deterioration of solid insulation by currents of enormously high frequency, that we cannot fail to see that advantage is gained by using currents of low frequency. Another very important fact is that with low frequency we are less troubled by the capacity of cables, and we have less loss of static charge accompanied by heating of the insulation. Again, the serious troubles which have been encountered at Deptford and elsewhere owing to abnormal rises of electric pressure in the mains above the pressure generated by the dynamos, due to the resonant effect produced by the capacity of the cable and the self-induction of the circuit, may be reduced as much as we please by sufficiently lowering the frequency. All these facts are the explanation of what has been thoroughly established in actual practice, namely, that there are difficulties on the line when using high frequencies which tend to loss of power and to destruction of the insulation, and that these difficulties are largely mitigated, if not entirely obviated, by reduction of the frequency. It must also be remembered that if we reach a frequency as low as 16 periods per second, any induction in neighboring telephone circuits is utterly inappreciable by the ear. Finally, all eddy currents diminish as the square of the frequency. Having now stated as clearly as I can what seemed to me the principal advantages of low frequency, I will place on the other side the disadvantages.

Besides the increased cost of transformers, there is one fact which is apt at first sight to impress one as almost fatal to the employment of very low frequency, but which further consideration shows to be of little moment in the case of Niagara Falls; this is, that a low frequency is not suitable for electric lighting directly. But it must be remembered that it is decidedly preferable to use a direct current for arc lamps, and, in fact, in the present position of the art in America it would be almost a necessity. Hence the natural method of arc lighting would be to use the alternating current by means of a motor to drive the well-known arc lighting machines. In the course of the work at Niagara, the first work in connection with arc lighting which will be set up is the lighting of Buffalo. At present this is done by means of steam engines, developing about 3,000 H. P. and driving arc lighting machines of the Brush, Thomson-Houston and Wood type. There cannot be a doubt that, financially and practically, the best way of converting this station to enable them to use the power from Niagara Falls is to put in alternating motors in the place of the steam engines; and this will be the case in most of the towns which will be supplied with power from Niagara Falls.

(To be continued.)

Boston Notes.

An unusual and unique Thanksgiving present was made on Thanksgiving Day by the directors of the Globe Street Railway Company, Fall River. It consisted of a purse of $450 divided among fourteen employes who were considered to be the most deserving and efficient in the company's employ. The division was made as follows: Two conductors and two motormen received $50 each; two conductors and two motormen got $30 each; two conductors and two motormen got $20 each. One motorman and one conductor got a special prize of $10 each. The gifts were fully appreciated, and such substantial recognition of the services of employes cannot fail to act as an incentive to others, and is a credit to the generosity of the directors. This was such an unusual gift that it deserves to be recorded.

The heating of street cars by electricity will, the present winter, be very general throughout New England, inasmuch as the firm of James F. Shaw & Company, Boston, has sold to no less than sixteen different New England street railway companies electric car heaters of the type made by the American Electric Heating Company under their own patents. Last winter some few cars in this district were heated by electricity, and gave satisfaction, hence the more general adoption.

It is highly creditable to the boys of Lynn who formerly were employes of the General Electric Company that notwithstanding the chronic paralysis from which the Trust is suffering, with every indication of a speedy dissolution, they keep up their spirits, feeding them doubtless on the hope of brighter, better days dawning ere long. Mid all the changes and dismissals and "laying offs," the members of the Thomson-Houston Electric Brass Band keep up their practice and musical engagements, the football club keeps the ball a-rolling, while the Thomson Scientific Club remains, not as lusty as formerly, yet strong enough to furnish some food for the intellectual delectation of its aspiring and and ambitious members.

In the annual report of the West End Railway Company, just issued, it is stated: "At the close of the year about five-sixths of all the mileage, namely, 1,325,000 miles per month, was run by the electric system. It is expected that during the coming year that system will be so extended as to cover most of the important lines. The board of directors have undiminished confidence in the electric system, and the increased riding, wherever it is introduced, proves clearly that the public consider it a great improvement over horse power. This fact and the comparative cheapness of operation, in the opinion of the directors, justify the large expenses involved in the introduction of the system." The West End Company has now 182½ miles fully equipped with electricity and 25½ miles partly equipped. The revenue miles for the year were 18,669,809, number of passengers carried 133,863,618. Of the passenger receipts 80 30 per cent. was from the electric lines and 19.67 from horse lines.

An important meeting of Fire Underwriters, representing the various Eastern Insurance Exchanges, was held at the National Insurance Board Rooms, New York, November 23d and 24th. Those present constituted the Conference Committee appointed to prepare a standard and schedule for electrical light and power stations, electric car sheds and repair shops. Representatives of the Eastern Fire Underwriters' Association were present and did some valuable work. The schedules for the above classes of risks, previously prepared, were gone over section by section, and the results were unanimously adopted by the committee to be recommended to the various boards represented. It is believed that the adoption of the proposed schedules will place these risks on a fairly paying basis, and at the same time will give the assured the benefit of good construction and equipment and such improvements as may be made.

---

* "Impedance," by A. E. Kennelly, American Institute of Electrical Engineers, April 18, 1893.

As was to be expected, the incandescent lamp makers of New England felt a good deal interested in the question of the Edison patents, and would have rejoiced to read an authoritative utterance to the effect that said patents died simultaneously with those in England. Such an utterance has not been as yet delivered, and so they anxiously await an expression of judicial opinion on the subject. Meantime the General Electric Company, as if to direct attention from its sure but gradual dissolution, is indulging in a little more of its would-be monopolistic litigation. Incandescent lamps, their inventors and manufacturers, however, are like Banquo's ghost, they "will not down."

Prof. W. L. Puffer of the Massachusetts Institute of Technology is engaged in giving a course of twenty-four lectures on "Practical Electricity" in the Wells Memorial Hall, the course being largely attended. On Friday evening his topic was "Dynamos." Many questions were asked and answered.

By a printer's error there appeared a statement in our last issue announcing the payment of a regular quarterly dividend of 14 per cent. by the New England Street Railway Company. It should have been 1¼ per cent. per quarter or 5 per cent. per annum.

Drexel, Morgan & Company are now represented in the directorate of the West End Railroad Company in the person of Mr. Samuel Spencer, who has been elected director.

Conway is to have an electric street railway—a company with a capital of $50,000 having been organized for that purpose. Power is to be taken from the water in Conway Gorge.

General News.

What is Going on in the Electrical World.

Homer, Mich.—A new electric lighting system is to be established here, it is said, to take the place of that already in use which has failed to give satisfaction.

Harrison, N. J.—The General Electric Company has notified the machinists at its factory here that their wages will be reduced from 30 cents an hour to 22½ cents.

Columbia, S. C.—A cotton mill is nearly completed here which is to get its power from the canal by means of electricity, instead of the old-fashioned belt method.

Martinsville, Ind.—The plant of the Martinsville Electric Light and Power Company, which went into the hands of an assignee last June, has been sold at auction to the Central Thomson-Houston Company of Cincinnati for $7,500.

Pittsfield, Mass.—The Stanley Electric Manufacturing Company held its annual meeting Tuesday of last week. The capital stock has been raised from $100,000 to $200,000, the new stock having all been taken.

Plainfield, N. J.—The consent of a majority of the propertyowners having been secured for the proposed extension of the electric railway to Dunellen, nothing remains to delay the building of the road except to obtain consent of the city council.

Bridgeport, Conn.—The Traction Company will use the trolley as a motive power on its lines. As soon as the company gets permission from the council the generators, poles, etc., will be ordered and the road double tracked. It is estimated that cars ought to be running by summer.

Cincinnati.—City Electrician Cabot the other day discovered a thief wire running from the main lines into a chimney over Kelly's pool rooms in Covington. Another wire, intended as an extra one in case the first one failed, was discovered at another point. The pool room people had been using the stolen current since the latter part of October.

Woonsocket, R. I.—The new plant of the Woonsocket Electric Machine and Power Company is about completed and will be in operation in a few days. Water is the motive power for driving the dynamos, two pairs of 36 in. turbines developing 600 H. P. being used. Three generators, each of 150 H. P., will be installed.

Riverhead, L. I.—Edwin G. Duryea has engaged the services of Electrician Scott of Jamaica to estimate the cost of constructing an electric road between Riverhead and the south side, connecting with Quogue and West Hampton. If the road is built the power is to be obtained from the Riverhead Electric Light Company's plant.

Lebanon, Pa.—A new electric ore separator has been set up at Meily's furnace by Sanders & Thompson, of Philadelphia, for exhibition. The aopacity of the separator is said to be four tons per hour, and is intended to take the place of ore roasters. The ore is ground and by means of a powerful magnet foreign substances are eliminated.

Washington, D. C.—H. N. Allen, Vice Consul General of the United States at Seoul, Korea, has informed the State Department that the king of Korea has recently purchased in America an incandescent electric light plant, which will be used for lighting the king's palace and surrounding grounds.

Ithaca, N. Y.—The Thomson Electric Welding Company, through F. P. Royce, have notified Dr. Thurston of their shipment to Cornell University, for the collection of Sibley College, a selected lot of samples of electrically welded work which has been on exhibition at the Fair at Chicago, with the frames and stands used there in exposing them.

Beatrice, Neb.—Paul Horbach has been removed from the receivership of the Beatrice Rapid Transit and Power Company, and Judge Brush has appointed M. C. Steele in his place. The new receiver will at once resume operation of the plant, and furnish the city with electric lights and electric street railway service.

Carlisle, Pa.—The Cumberland Valley Electric Passenger Railway Company has been reorganized under the name of the Cumberland Valley Traction Company with the following officers: President, S. Ritter Iokes; directors, John R. Lemon, Tyrone, Pa.; William J Iokes, Altoona; John R. Miller, Charles and William Wigton, Altoona, Pa.

New York.—The Rapid Transit Commission has adopted a resolution favoring the West Side Rapid Transit scheme. The resolution stipulates that the structure shall be capable of carrying five-car trains, run at an average speed of thirty-five miles an hour, to be run by electricity or some other power needing no combustion along the line of the road.

Syracuse, N. Y.-Elijah D. Fulford, who has been the superintendent of construction for the American Long Distance Telephone Company during the building of its new line from St. Louis to New York, was arrested here last week on a train while on his way to New York for alleged fraudulent entries in his accounts, involving a loss to the company of a large sum of money.

Salem, Mass.—The 400 horse power generator of the Lynn and Boston Street Railroad Company which has been located in the stations of the Salem Electric Lighting Company has been removed, and now the latter company furnishes all the power for the operation of the cars on the local division of the road from its new station.

Rockford, Ill.—It is understood that the National Thermograph and Electrical Company, which has long been located at Chicago, is to remove its works to this place. The officers of the company are: George H. Sisson, of New York, president; Wm. J. Marks, Chicago, treasurer; H. F. Crow, Chicago, secretary; and A. E. Appleford, general manager.

Lynn, Mass.—In addition to the cut in wages hitherto made at the factories of the General Electric Company another notice was posted in the works a few days ago reducing the wages of all employees paid by the hour whose pay had not heretofore been reduced, and the factory auditor has been given instructions to make reductions in all piece work.

St. Joseph, Mich.—The council has granted a franchise to the St. Joseph and Lake Shore Railway Company and the St. Joseph Electric Light and Power Company to construct an electric railway from the centre of the city to the southern limits, and to furnish electric power and light to St. Joseph. The company is composed of Chicago capitalists, and the railway and light plant are to be in operation by August 1.

New Haven Conn.—The Manufacturers' Street Railway Company have opened subscriptions for an electric road from Grapevine Point to connect with the Consolidated road at Cedar Hill. Whether the company will have its own plant or will take power from the power house now in process of erection for the State street road system is a matter undetermined. The incorporators are George S. Barnum, Frank L. Bigelow, Simson J. Fox and W. W. Kendall.

Rochester, N.Y.—Since the Grand View Beach Railroad Company's power house at Rigney's Bluff was destroyed by fire, several months ago, power from the Rochester Railway Company's lines has been used. Next season, however, the company will generate its own electrical force at a plant in Charlotte.—Frank W. Hawley, vice-president of the Cataract General Electric Company, has been interviewed in regard to State Engineer Schenck's published opinion that electricity as a motive power would be a failure on the canals. Mr. Hawley differs from Mr. Schenck ever so much, and intimates that the latter is no authority on the subject. After disposing of Mr. Schenck's theories, and pointing out the advantages of electricity in canal navigation, Mr. Hawley says: "Opposition is expected. It comes to all things in the way of progress. It helps to develop the best methods."

Baltimore.—The Brush Company has notified the Maryland Electric Company that it is now sufficiently recovered from the recent fire to furnish the 1,030 lights required by the city and will no longer permit the use of its wires and poles by the Maryland Company, which has been supplying current for 229 lights. The Brush Company has the city contract.—The First and Second Branches of the city council have passed an ordinance directing the mayor, comptroller and city register to contract with any existing electric light company to light the streets, lanes, alleys, public squares, public buildings and other places where electric arc lights are now used by the city, or shall be authorized to be used by the general superintendent of lamps. The contract is to be for a term of five years at a price not exceeding 35 cents a lamp each night, and the city is to have the privilege of terminating the contract at the end of any two years by giving the contracting company thirty days' notice. The lights are to be kept burning from sunset until daybreak, the company being subject to a penalty of $1 for every lamp that fails to burn nightly. The company receiving the contract is to be bonded in $20,000 to insure its fulfilment—A trust mortgage for $1,000,000 from the Maryland Electric Company, of Baltimore, to the State Trust Company, of New York, has been recently recorded. It is to secure the issue of 900 bonds of $1,000 each and 200 bonds of $500 each by the electric company. The mortgage is secured by the property, rights and franchises of the electric company.

THE KNAPP ELECTRICAL WORKS.

Notice of Removal.

About Jan. 1 the Knapp Electrical Works, Chicago, are to move from their present quarters to 271 and 273 Franklin street, where their facilities are to be doubled. The new building has a floor space of 40 000 square feet, which is very nearly double that of their present building.

The offices, salesroom and shipping department will be located on the main floor. The two upper floors will be devoted to the manufacture of their many popular specialties. The balance of the building will be filled with a large stock, which will enable them to fill almost any order the same day of its receipt.

They are also building a factory fifty-two miles from Chicago, where they are to manufacture such articles as require a great deal of room.

This company has recently taken up the manufacture of fixtures, combination electric and gas, and are getting up new and original designs, and it is their intention to make a very fine display of this line in their new store.

The growth of this company is something remarkable. They deal only in electrical supplies, and do not enter into competition with manufacturers of lighting apparatus.

Among the valuable agencies which this company controls are that of the Safety Insulated Wire and Cable Company of New York and the Columbia Incandescent Lamp Company of St. Louis.

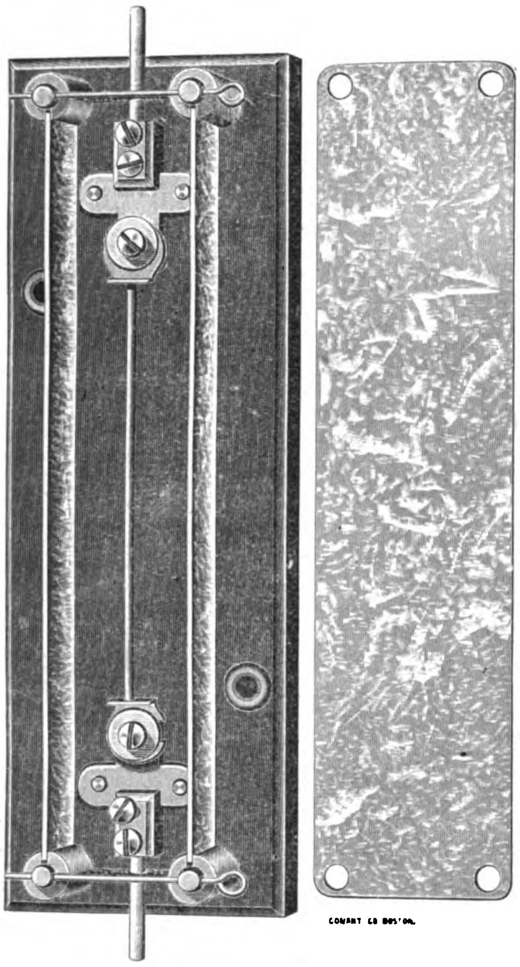
Over five million feet of the safety wire was used at the World's Columbian Exposition, and one hundred and sixty thousand feet of their lead covered cables is used in the South Park Boulevard lighting system.

The Knapp Electrical Works intend fitting up offices in their new store which will be as fine as those of any house in this line of business in this country, and will always be glad to welcome their friends and customers to their new home at 271 and 273 Franklin street, Chicago.

A Covered Fuse Box.

The illustration accompanying is that of a Covered Fuse Box for use on a 500-volt circuit, recently perfected and placed on the market by the W. S. Hill Electric Company, of Boston, Mass. The metal terminal blocks are mounted on a slate base, and the parts are all protected by a box made of mica, the removable cover of which is held in place with two wire pins, so as to be readily removed to permit of replacing a blown fuse.

For some time past there has been a very large demand for a light, compact covered 500-volt Fuse Block, and the above enterprising company in producing this show their ability to keep fully up to the times in this line, as well as in switches and switchboards; hence it is no surprise to hear that they are having to seek a much larger factory, their business being now so extensive that they have quite outgrown their present factory.



A COVERED FUSE BOX.

Royal Arc Lamps.

Mr. J. J. Gates, manager of the Connecticut Royal Arc Company, has close a contract with the Hartford Electric Light Company for 800 Royal Arc equipments, which are to be attached to the arc lamps at present in use on the local company's circuit.

The contract was made after a thorough test of the new lamps by the electric light company.

The Westinghouse Company's New Factory.

The Westinghouse Electric and Manufacturing Company will advertise at once for bids for the erection of new works at Brinton. At that place the company has secured twenty-three acres of land.

The plans for these buildings have been under consideration and elaboration for the last five months, and every detail of manufacture has been most carefully considered, and the buildings finally decided upon are a machine shop 754 feet long and 231 feet wide, a two-story warehouse of the same length, and a suitable power house for the operation of all the machinery. These buildings will give the Electric Company a capacity of $1,000,000 output per month, which under pressure can be greatly increased.

Especial attention has been given to the arranging of the storeroom and warehouse for the carrying of supplies and manufactured material in such a manner that the least possible amount of material will be required with the minimum cost of handling, and the tools have also been arranged with reference to economy in handling the material. The central part of the machine shop will contain most powerful electric cranes, capable of handling the largest pieces of machinery that will probably be needed in the future for electrical apparatus. The buildings in general design are in many respects like those erected by the Air Brake Company at Wilmerding, but are much larger, and include such alterations as have been found necessary for the different classes of work. The buildings will be practically fire-proof.

The advantages to be gained by the Electric Company by moving its manufacturing plant into this establishment, as compared with its present arrangement, will be enormous.

At the present time the Electric Company is employing about 2,000 hands, and has been constantly adding to its force during the past sixty days.

INCORPORATIONS.

The Brooklyn, Queens County and Suburban Railroad Company, Newtown, N. Y.—to construct a street surface road about five and one-quarter miles in length in Queens County, N. Y. Capital stock, $15,000,000. Directors: Frank Bailey, Edward Johnson, George H. Southard, Henry E. Hutchinson, Frederick T. Aldridge and Julian Fairchild, of Brooklyn; Cassius M. Wicker and Francis P. Lowey, of New York City, and Henry T. Bragg, of Yonkers.

The Villisca Electrical Company, Villisca, Iowa—to erect and operate an electric light and power plant at Villisca. Capital stock, $25,000. Promoters: M. N. McNaughton, W. S. Alger, H. C. Stoddard, B. F. Fast, all of Villisca.

Midway Electric Light Company, St. Paul, Minn.—to produce, generate, transmit, furnish and sell electricity for the purpose of supplying light, heat and power and for other purposes. Capital stock, $30,000. Promoters; Geo. B. Lynch, E. A. Forbes, G. F. Downing, St Paul.

The Parsons Electric Light Company, Parsons, W. Va.—to furnish electric light, heat and power to towns, corporations and individuals, etc. Capital stock, $100,000. Promoters: Thos. B. Gould, Jno. P. Harford, J. S. Dougal, Parsons, W. Va.

The Hough Electric Company, San Francisco, Cal.—to manufacture and deal in electrical apparatus and machinery and deal in patents and inventions. Capital stock, $1,000,000. Promoters: Edw. S. Hough, Jos. Hough, Ernest Hough, LeRoy G. Harvey, Jno. M. Beck, Oakland, Cal.; Howard E. Wright, San Francisco; C. L. Wingley, Jr., Oakland, Cal.

The Progressive Manufacturing Company, Camden, N.J.—to manufacture and sell electrical devices slot machines, and other coin control devices, cigar store fixtures and devices, etc. Capital stock, $200,000. Promoters: Samuel Welsh, Chas. M. Keegan, Philadelphia, Pa; John B. Adams, Camden.

The Northwestern Telephone and Electric Company, Milwaukee, Wis.—to deal in telephone and other electrical supplies. Capital stock, $50,000. Incorporators: A. B. Ferdinand, H. C. Dodge and H. H. Spencer.

The La Junta Electric Company, Denver, Col.—to furnish electric plant for the town of La Junta, Otero County, Col. Capital stock, $25,000. Promoters: Chas. F. Lacombe, Geo A. Goddard, Denver; Auen G. Bentley, La Junta, Col.

The Water and Improvement Company of St. Charles, St. Charles, Mo.—to conduct a system of water works and a light, heat and power plant at St. Charles. Capital stock, $100,000. Promoters: H. C. Scott, Thomas Fox, I. H. Lionberger, St. Louis, Mo.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 21, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

509,002. Electric Railway. Jonathan H. Vail, New York, N. Y. Filed March 17, 1893.

509,065 Electric-Railway Conduit. Granville T. Woods, New York, N. Y., assignor to the Universal Electric Company of the City of New York. Filed Oct. 14, 1892. Renewed Sept 25, 1893.

509,072. Electric Railway. John H. Dale, New York, N. Y., assignor to the Universal Electric Company of the City of New York, same place. Filed March 1, 1893.

509,123. Trolley Mechanism. James T. Fuller, Calvert, Tex. Filed July 17, 1893.

509,311. Electric Locomotive. John C. Henry, New York, N. Y. Filed Dec. 15, 1891.

509,312. Supply System for Electric Railways. John C. Henry, New York, N. Y. Original application filed Aug. 20, 1889. Divided, and this application filed April 29, 1892.

509,328. Hanger for Trolley-Wires. George H. Ricke, Cincinnati, Ohio, assignor of three fourths to Owen M. Hilland, Michael A. McGuire and Charles C. Agin, same place. Filed Aug. 7, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

508,926. Casing for Electric-Arc Lamps. Peter Federmann, Berlin, Germany. Filed Feb. 23, 1893.

509,014. Electric-Arc Lamp. Henry P. Ball, Brooklyn, assignor to the Edison General Electric Company, New York, N. Y. Filed March 2, 1891.

509,036. Automatic Thermal Cut-Out for Incandescent Electric Lamps. Edward H. Johnson, New York, N.Y., assignor to the Edison Electric Light Company, same place. Filed 3, 1886.

509,167. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 29, 1893.

509,168. Electric-Arc Lamp. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed June 29, 1893.

509,188. Electric-Arc Lamp. Barton B. Ward, New York, N. Y. Filed Feb. 15, 1893.

509,297. Socket for Electric Lamps. Waldo C. Bryant, Bridgeport, Conn., assignor to the Bryant Electric Company, same place. Filed March 22, 1893.

SIGNALS AND SIGNALING APPARATUS.

508,946. Automatic Railway Electric Signal. Burton A. Karr and Charles H. Bradrick, Omaha, Neb., assignors to the National Railway Signal Company, same place. Filed Dec. 27, 1892.

509,093. Electro-Mechanical Slot Mechanism for Railway-Signals. Thomas H. Patenall, Rahway, N. J. Filed Jan. 6, 1893.

509,171. Electric-Signal Receiver. William H. Kirnan, Bayonne, N. J., assignor to the Gamewell Fire Alarm Telegraph Company, New York, N. Y. Filed April 17, 1893.

509,201. Railway-Train Order and Signaling Device. Leonard T. Crabtree, New London, Wis. Filed June 24, 1893

509,217. Combined Electric Time-Stamp and Signal Device. Thomas F. Gaynor, Louisville, Ky., assignor, by mesne assignments, to the New Gaynor Electric Company, same place. Filed March 7, 1891.

509,218. Electric Signal Device. Thomas F. Gaynor, Louisville, Ky., assignor, by mesne assignments, to the New Gaynor Electric Company, same place. Filed March 16, 1891.

509,244. Electrical Apparatus for Controlling Signal or Other Circuits. Homer A. Parrish, Jackson, Mich., assignor of one-tenth to Eugene J. Weeks, same place, and George A. W. Dodge, New Haven, Conn. Filed Jan. 28, 1893.

MEASURING INSTRUMENTS.

509,095. Electric Meter. John Perry, London, England. Filed March 28, 1893.

509,342. Ampere-Meter or Voltmeter. Carl Wilkens, Frankfort-on-the-Main, assignor to Hartmann & Braun, Bockenheim, Germany. Filed July 19, 1893.

BATTERIES.

509,266, 509,267, 509,268, 509,269, 509,270, 509,271, 509,272. Storage Battery. Edward P. Usher, Grafton, Mass., assignor to the Hopedale Electric Company of West Virginia. Filed Jan 23 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

509,061. Speaking Attachment for Telephones. William Weber and George Weber, Philadelphia, Pa. Filed Sept. 16, 1893.

509,066. Telegraphy. Julien P. Wooten, Bainbridge, Ga. Filed Nov. 18 1892.

509,186. Telephone Exchange Apparatus. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Feb 21, 1893.

509,216. Fire Alarm Telegraph Repeater. Thomas F. Gaynor, Louisville, Ky., assignor, by mesne assignments, to the New Gaynor Electric Company, same place. Filed March 2, 1891.

509,219. Non-Interference Signal Box Mechanism for Fire Alarm Telegraphs. Thomas F. Gaynor, Louisville, Ky., assignor, by mesne assignments, to the New Gaynor Electric Company, same place. Filed March 19, 1891.

509,290 Signal Telegraph. Claudius V. Boughton, Buffalo, N. Y., assignor, by direct and mesne assignments, to the Boughton Telephotos Company, same place. Filed Nov. 26, 1892.

MISCELLANEOUS.

508,914. Device for Singeing Cloth. Rudolph M. Hunter, Philadelphia, Pa. Filed July 16, 1890.

509,050. Electric Bell. William J. Schweiger, New York, N. Y., assignor of one-half to Hermann Apfelbaum, same place. Filed March 15, 1893.

509,075. Base for Stereotype or Electrotype Plates. Herman Fietsch, Jr., Chicago, Ill., assignor to Daniel W. Ryan, same place. Filed Feb. 20, 1893.

509,085. Electric Cigar Lighter. Christian J. Jenne and Charles E. Willey, Louisville, Ky., assignors to William Carter, John W. Dawson and Joseph Meyrick, same place. Filed April 5, 1893

509,091. Magazine Gun and Electrical Devices Therefor. John L. McCullough, Brooklyn, N. Y. Filed Dec. 12, 1892.

509,116. Electrically-Controlled Door. Frank Callagan, Bridgeport, Conn., assignor to Jacob B. Klein, same place. Filed April 8, 1892.

509,124. Process of Preparing Plates for the Purpose of Utility and Ornament. Hannibal Goodwin, Newark, N. J. Filed Jan. 28 1887.

509,279. Regulating Switch for Electric Elevators. Henry A. Allen, Chicago, Ill., assignor to the Eaton & Prince Company, same place. Filed Feb 20, 1892.

509,322 Current Controlling Device. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan, Sr., Thomas R. Morgan, Jr., and John R. Morgan, same place. Original application filed July 22, 1891. Divided and this application filed Sept. 22, 1892

To Inventors and Others.

United States and Foreign Patents Procured.

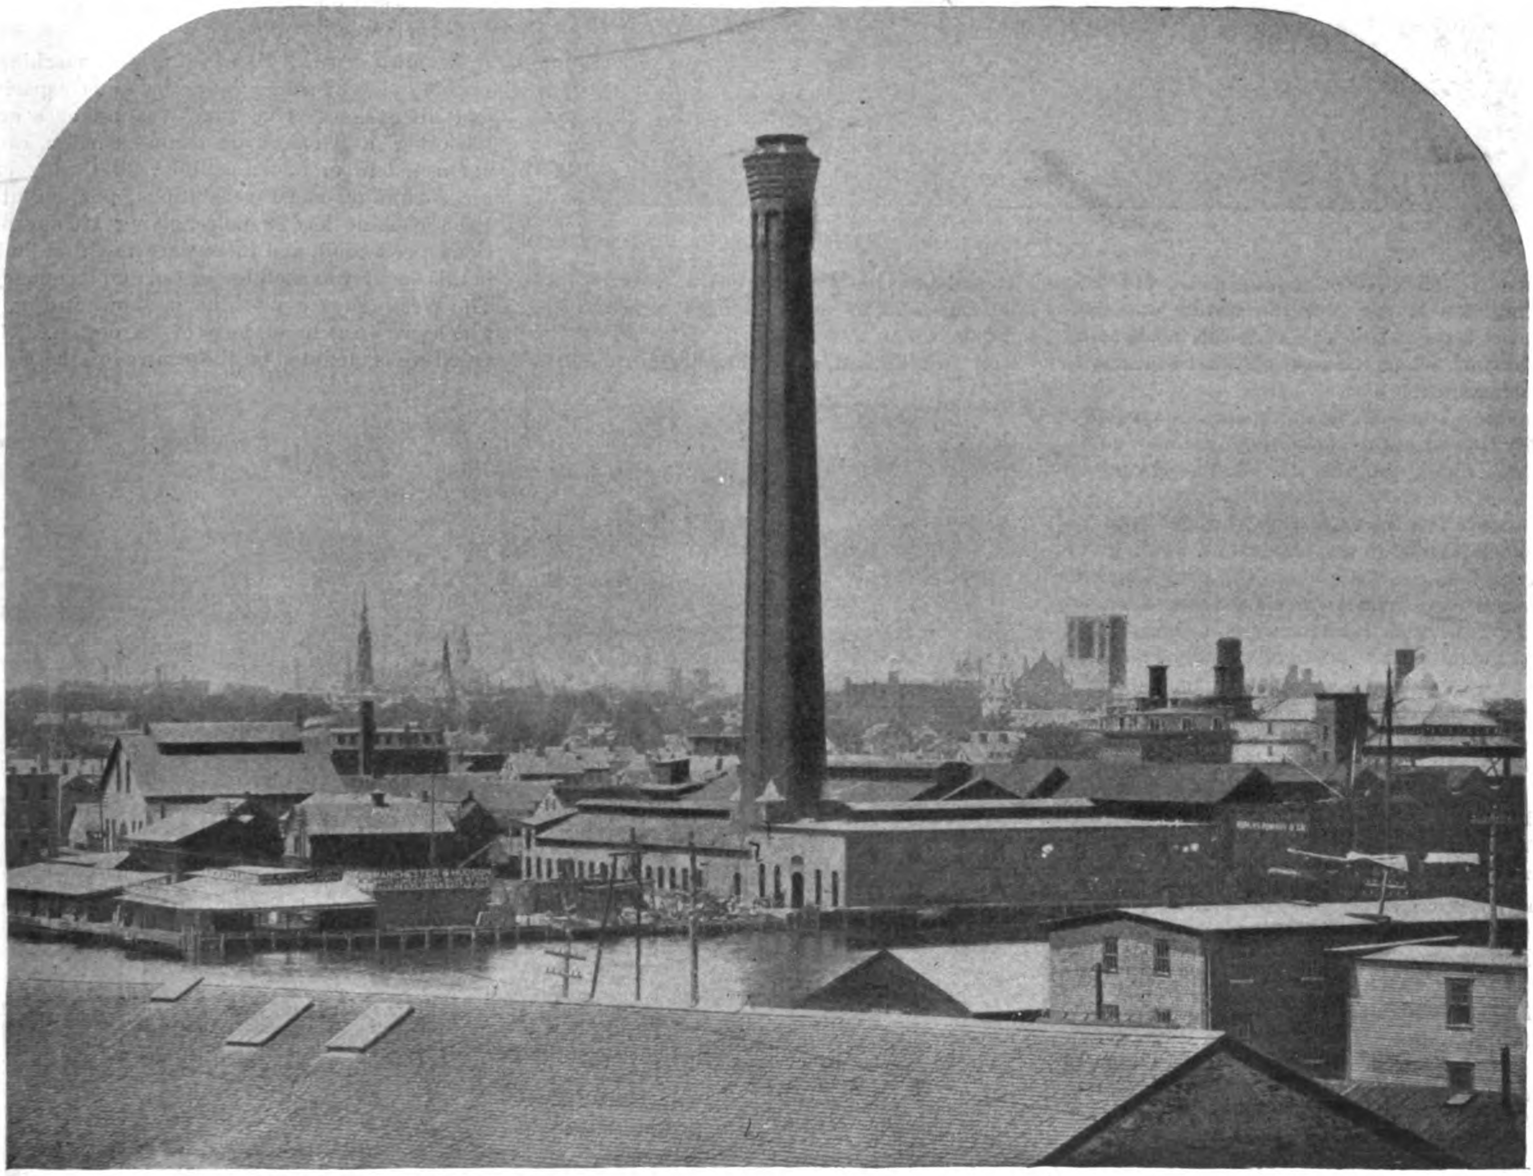
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. DECEMBER 13, 1893. CHICAGO. No. 22



THE NARRAGANSETT STATION, PROVIDENCE, R. I. (SEE PAGE 258.)

The Narragansett Station.

Its Special Machinery and Unique Equipment.

The city of Providence contains an electrical central station which is in many respects distinctly original, both in regard to its general design and the style of machines with which it is equipped. The present arrangement was not contemplated at the time the station was first built, but is the result of extensions made from time to time, which the steady growth of its business demanded.

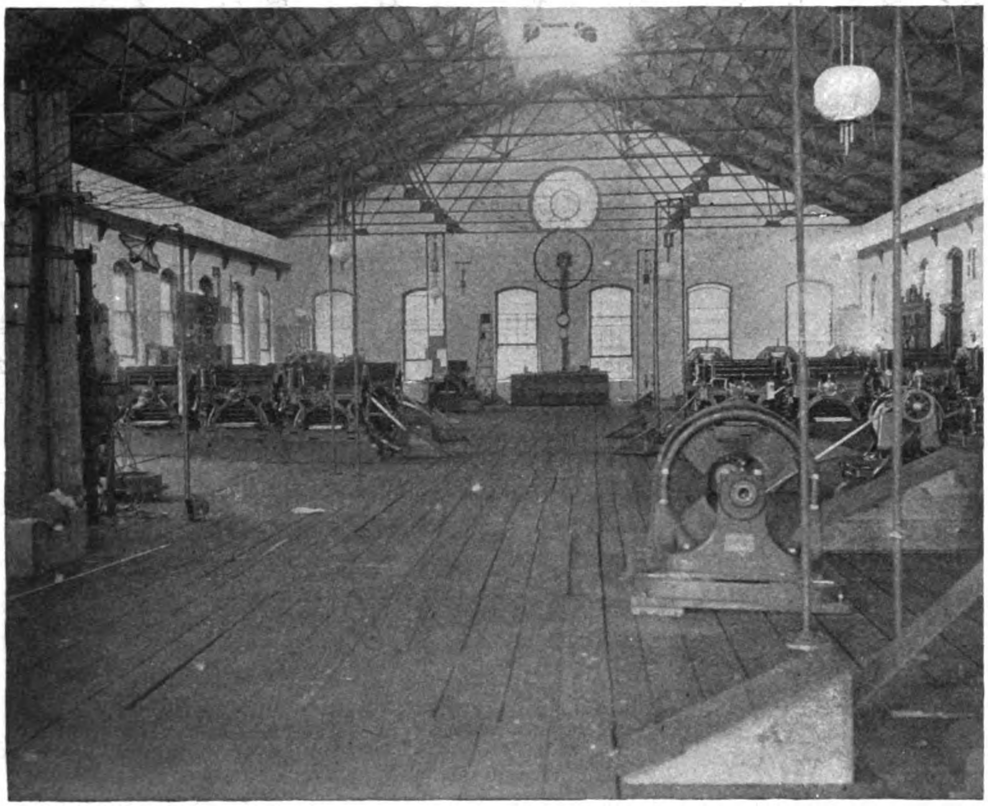


FIG. 1.

The latest additions to the plant are specially worthy of attention, as they include some dynamos which are the first and only ones of their kind in use.

The station, as will be seen from the Frontispiece, is situated on the waterfront, which gives it special facilities for condensing purposes, and is a large, substantial brick structure whose interior is divided into three main rooms, the boiler room, engine room and dynamo room.

The boiler room occupies the end of the building facing the water, and extends across its entire width, the two rows of boilers being parallel to the waterfront. In the rear of this a partition running lengthwise through the building divides it into two long rooms, the one on the right containing the dynamos and the other the engines and the large direct connected machines.

The plant contains eight boilers, four of the Babcock & Wilcox make and four of Moore's National boilers. These are set in batteries of two boilers each, and are run so as to give about 160 lbs. pressure at the engines. Blake and Worthington pumps are used for feeding the boilers and condensers. The aggregate capacity of this steam plant is about 5,000 horse power, an amount which is only exceeded by but few stations in this country.

The dynamo room, a portion of which is shown in Fig. 1, is raised a little above the level of the boiler room floor, and a line of shafting runs below the floor in the middle of the room and along its entire length from which the belts run up to the machines arranged along either side of the room.

There are no less than fifty-five dynamos in this part of the station, whose capacities aggregate more than 3,000 horse power. These include thirty 50 light (2,000 C. P.) Thomson-Houston arc machines, seventeen 50 light (1,200 C. P.) Thomson-Houston arc machines, two 90 K. W. 500 volt and two 60 K. W. 500 volt Thomson-Houston dynamos, two 4,000 light and two 3,000 light Westinghouse alternators.

In addition to the switchboard, described below, a new one 25 feet in length is now being built for use in this room.

The switchboard, which has been installed in place of the one built by the Thomson-Houston Electric Company, is composed of five panels of white Italian marble, and is six feet high, fifteen feet long, having elegant brass mountings and illuminated by incandescent lamps placed on top of the brass caps which surmount the iron tubular columns supporting the panels in their places side by side. This elegant piece of work has connections for fifty circuits and is to control fifty dynamos. The plugs are composed of aluminum bronze, with solid mahogany handles, every hole in the marble board being lined with fine brass bushings. This switchboard was designed throughout by Mr. C. H. Herrick, electrical engineer, Boston, and built by the W. S. Hill Electric Company, Boston. As a piece of apparatus it is entitled to rank as the handsomest and best piece of work of its kind ever made.

The circuit wires enter and leave the station by way of an iron tower specially designed and built by the Berlin Iron Bridge Company of East Berlin, Conn. This tower is twenty feet square and thirty feet high, and no less than 225 different wires are carefully accommodated in it. This tower and all the wiring were put in under the personal superintendence of Mr. Herrick.

The really unique part of the equipment is in the engine room however, where the three large direct-connected dynamos are situated. The smallest of these is a six-pole 500 volt generator of the Thomson-Houston type, driven by an Allis-Corliss engine running at 90 revolutions per minute. This has a capacity of 250 K. W., and is used, together with the 500-volt dynamos mentioned above, for supplying motive power. A number of small manufacturing shops are run from this station, the largest of which consumes 50 horse power.

The two special direct-connected machines, running side by side, are of the same capacity and dimensions. One is a Westinghouse and the other a Thomson-Houston machine, each connected to cross-compound Allis-Corliss engines running at 90 revolutions per minute. Each machine has 80 poles, giving 120 alternations per second, and these were the first built in this country at such low speed and frequency. The Westinghouse machine is shown in Fig. 2, which gives a general idea of its design. The armature is mounted on the centre of the shaft between the two engine cranks, and is 12 feet 3 inches in diameter.

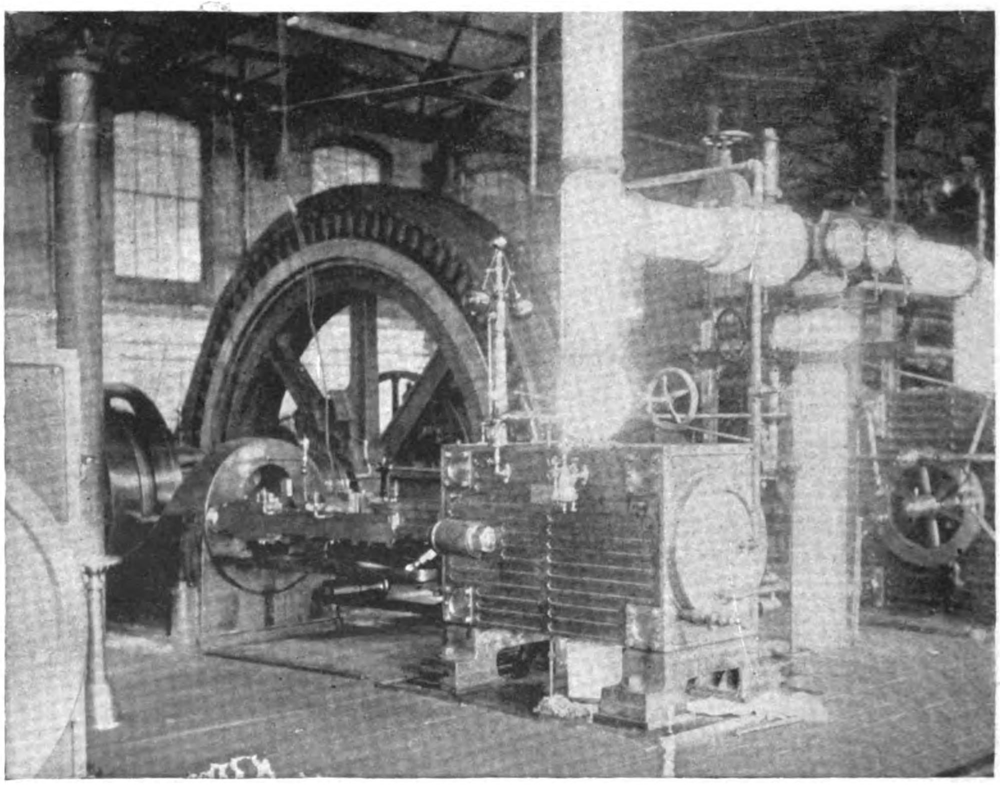

FIG. 2.

The field rests on separate foundations, and is set on tracks parallel to the armature to permit its movement to the position shown in Fig. 3, in order to remove or repair the field or armature coils. The exciter stands at the crank end of the engine, and is belted to a pulley on the armature shaft. No special means of regulation is employed.

The Thomson-Houston generator is very similar to the above in its general outline, and has the same number of poles, diameter of armature and number of revolutions. The method of regulation, however, resembles that known as the Wall controller used with the Thomson-Houston arc machines. It has two exciters, or rather one exciter which itself has an exciter. The dynamo which supplies the field of the large generator is a multiple wound machine, and the field of the latter is a series machine. The result of this arrangement is to bring a change of load very gradually onto the generator, and it therefore gives the engine time to adapt itself to the change without any noticeable variation in speed.

Both of these large machines are so wound that the primary circuit may run at either 1,000 or 2,000 volts. For the former pressure the armature coils are connected all in series, and for the latter the two half series are put in multiple. This change is made by a single switch to which the windings are connected.

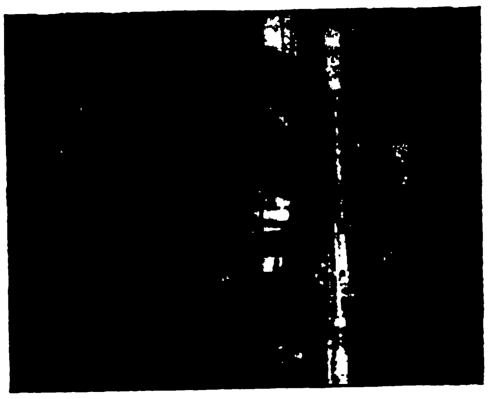

FIG. 3.

Besides the three direct connected engines are three others, all of the same type, which are belted to the shafting under the dynamo room. Two of these are cross-compound of 300 H. P. and 1,200 H. P. respectively, and one 1,500 H. P. triple expansion engine. The latter and the two large direct connected machines run with independent condensers and the others with one large condenser in common.

The total incandescent light service wired for is equivalent to 21,800 lamps of 16 C. P., the maximum output of the station being about 70 per cent. of this amount.

The arc service includes 2,066 lamps in operation, 1,392 of which are contracted for by the city of Providence and the remainder private lighting. This very large service makes the use of such large units possible, and it is expected they will considerably increase the economy of the plant and simplify the operation of the station.

Professor Elihu Thomson in the course of a lecture on lightning and high potentials in Lynn lately received in his body a discharge from a 1,000,000 volt current. Professor Thomson stated that he inclined to the belief that lightning is caused by the action of the sun on the clouds through the ether, arguing that if the sun can produce the aurora borealis in the light thin air, which he produced by electrical apparatus, there is reason to think that in the dense air nearer the earth it can produce a current of high pressure that will strike through with brilliant discharges. He showed a completely safe protection from thunderbolts in the shape of a cage of brass wires, and declared that an umbrella held over the head with brass chains hanging from the ends of the ribs makes a complete protection.

The Electrical Transmission of Power from Niagara Falls.—II.

BY PROF. GEO. FORBES.*

It will be well at this point to say something about the frequency which is required to prevent the arc and incandescent lamps from flickering. I have made a number of experiments on these points, and my conclusions are as follows:—A 16 candle-power 50-volt incandescent lamp shows a flickering almost up to 25 periods per second, at which frequency the flickering ceases when at its normal brightness; but if pushed to an excess of incandescence, the flickering was just perceptible up to 27 or 28 periods. I believe that a 100-volt 16 candle-power lamp shows a perceptible flicker up to 28 periods; but I may mention that this flicker is not nearly so serious or perceptible as that which frequently arises from the employment of certain types of engines, especially single-acting high-speed engines, when sufficient fly-wheel momentum is not provided. As a case in point, I would mention the lighting in the Holland House, one of the best hotels in New York, where, to an experienced eye, the flicker of the lights in the large dining room from this cause is very objectionable. The thinner the filament, the more liability is there to such a flickering. I have lately examined the thick filament lamps to which the name of "Bernstein" lamps has been given, which consume 6 to 10 amperes at low voltage. It takes so long a time for the incandescence to die out when the current is stopped, that I have little doubt about their being able to work without any perceptible flickering at so low a frequency as even 16 periods per second. I have also made some experiments of a similar nature on arc lamps at low frequencies. At 37½ periods per second there was a very bad flickering, and this was most noticeable when looking at a piece of white paper illuminated by the naked light, or when looking at an opal shade put on the lamp. At 40 periods it was still bad. Neither at this speed, nor at the previous one, was there any serious noise, but at 40 periods the noise could be perceived by putting a glass globe over the lamp resting on the metal framework directly. At 41·7 periods there was just enough flickering to be objectionable; at 45 periods it was just possible to notice it on a printed page held close to the lamp, but it was not visible when reading at a distance of 10 feet. At 50 periods the only means of detecting anything of the sort was by looking directly at the arc; nothing was seen when reading a book either with the opal shade on or off. At this frequency the noise became much more perceptible, especially with a long arc about one-eighth of an inch. On reducing the length of the arc to one-sixteenth of an inch the noise was much less. In all these experiments the consumption of energy was at the rate of 26 volts and 14·2 amperes at the lamp terminals. The best cored carbons of Siemens & Halske were used.

An objection has been raised to the use of low frequency owing to the fact that a periodical twisting strain is given to the shaft of the dynamo, but this objection disappears almost entirely when we are dealing with a machine generating two phases.

It follows, therefore, that for arc and incandescent lighting at a very low frequency it becomes necessary to use alternating-current motor-generators, or else to use something of the character of a commutating machine to convert into continuous currents. Such machines as those exhibited by Schückert at Frankfort in 1891 are useful up to a certain extent, but they are expensive, and comparatively inefficient, as their only function is to commutate the current—an operation which ought not to involve any significant loss. At the present moment a good commutator for the alternating current is not upon the market, but the matter is of such prime importance that I feel confident that much will be done in this direction. In fact, I have seen enough with my own eyes to have no fear about our being able to generate continuous current from the two phase alternating current without serious loss, and with very inexpensive machinery. If, however, the object of our work was mainly, or even to a considerable extent, to provide the means of lighting towns by arc and incandescent lamps, I should have hesitated to recommend a reduction in frequency below 42 periods per second, such as is used by Ganz & Company, and which is operated so successfully at Rome and Tivoli, and at a very large number of other places on the Continent. The officers of the company and myself considered this matter most carefully, and, looking at the purposes for which our machinery is being set up, we felt sure that the proportion of electricity which would be used for lighting purposes would not be large, and that we must look upon our whole plant as a power producing and distributing plant, and that our object must be to distribute power in the most efficient and economical manner. This being the case, we agreed that it was desirable to lower the frequency so far as the mechanical conditions of the problem would allow. The lowest frequency which had been offered to us by the manufacturers was a very beautiful design of a machine at a frequency of 20 periods per second. This machine had admirable qualities, but was in some points not exactly adapted to the requirements of the situation, as developed by the selection of a special design for the turbine.

I have myself made several trials of designs at very low frequencies, even as low as eight and one-third periods per second, and for this frequency I prepared drawings of a machine which, though by no means perfect, shows a possibility of being worked into a sound machine of good mechanical construction; but further considerations led me entirely to modify the design of the machine, and eventually I arrived at the conclusion that, both from the point of view of design of the dynamo, and also for suitability of applying the current, 16 periods per second was probably as good as could be obtained. The manufacturers to whom the contract has been given were anxious to use a lower induction in the iron of the machine than that which I would have preferred, and this rendered the machine of 16 periods per second heavier than could be supported by the hydraulic piston which supports the whole weight of the turbine, vertical shaft, and revolving part of the dynamo. Consequently we have made a compromise, and are going to build our first three dynamos with a frequency of 25 periods per second. In concluding my remarks upon low frequency, I must again repeat that, from a purely practical and commercial point of view, one of the great advantages lies in the fact that for any special purpose for which a motor is required any ordinary direct current motor may be altered so as to act as a synchronizing alternating motor at a very small expenditure of time and money.

ELECTROMOTIVE FORCE.

The question of selecting a suitable electric pressure for working to Buffalo, and also for local purposes, is of some importance. Generally speaking, it is desirable to use as high an electric pressure on the line as is consistent with safe and continuous working, as this effects a great saving in the amount of copper used on the line. In the first report, founded on insufficient data, which I wrote more than three years ago for the Cataract Construction Company, I reccommended that 2,000 volts should be used in the neighborhood and that the pressure should be raised by means of transformers for the more distant transmission. But the greater portion of our work in the immediate future will have the character of distant transmission. In most of the tenders which were submitted to us the cost of transformers was almost as much as that of dynamos—in some it was more—so that the use of a step-up transformer for distant transmission meant almost double the cost of generating the current. I hold the view that a pressure of even 20,000 volts can be generated as safely in the dynamo machine itself as in the transformers, and that if we used 20,000 volts for the local work as well as for Buffalo, we should not be incurring the additional expense and losses of a step-up transformer, while we should be saving enormously in the cost of copper. Unfortunately, American manufacturers have never supplied alternating current dynamos at a higher pressure than 2,000 volts, and they are not practically acquainted with the experiences which have been gained in Europe at extra high pressure. Most of the manufacturers declared their inability positively under any conditions to go above 2,500 volts, although some of the engineers were willing to go as far as 5,000 volts. This, however, would have been no material gain to us; and the consequence is that, to meet the views of the manufacturers in our preliminary work—that is to say, in the construction of the first three dynamos for our power house—these will be only of such electrical pressure as they are accustomed to deal with. We shall therefore be using dynamos generating current at 2,000 volts, and employing step-up transformers for the extra high pressure. This may possibly render it desirable in our first work not to use the extra high pressure for local purposes. Besides the actual cost of the conductors, a very serious matter arises when we are dealing with the large currents due to comparatively low electric pressure. I refer to the large quantity of copper which has to be put into the conductors. Working at 2,000 volts, each phase of each of our generators will give nearly 1,000 amperes, without considering the effects of ratardation of phase, which will increase the current by quite a perceptible amount. So that, to put in the most economical section, will require 3 square inches for each conductor, or 12 square inches of copper for each 5,000 H. P. dynamo, or 36 square inches section of copper for the 15,000 H. P., which is now being supplied. When we remember that even with low frequency the question of skin resistance comes into play when the conductors have a large diameter, it is obvious that we are introducing serious troubles, and if a subway were to be made to carry these conductors it would require to be of very great dimensions. For these reasons I am still anxious to see the extra high pressure used even for the factories within a distance of a mile. The uniformity of the system would undoubtedly be of great benefit to us if we could generate the whole current for all purposes at the same extra high electric pressure, but as I have stated, we were obliged to content ourselves with a somewhat less perfect arrangement than would be adopted if we were dealing with the utilization of a waterfall in Europe.

---

* From a paper read before the Institution of Electrical Engineers, England.

I wish to lay stress on the importance which I have considered to lie in the fact of having a perfectly uniform system with interchangeable dynamos. Many engineers to whom I have talked have suggested the use of special dynamos at different pressures for special purposes; but if we had a special dynamo for arc lighting, and another for incandescent lighting, a third for street railways, another for electro-deposition and so on, the possibility of interchanging dynamos would disappear, and the whole system would be much more complicated to work.

I wish now to make a few remarks about the insulation which it has been customary to put upon dynamos and transformers which were to be used with high electric pressure. Many persons who have not given sufficient attention to the subject seem to be inclined to believe that there is something mysterious about the tendency of electricity in a dynamo or transformer to break through the insulation, and which prevents them from being subject to the ordinary laws of electricity. Thus, when building a dynamo for 2,000 volts, a thickness of insulation is given which would stand a test of more than 100,000 volts without breaking down, and it has been found from the ordinary methods of using the plant that if something of this sort is not done, the insulation will break down. I wish to point out that the reason for this lies in the fact, not that the insulation breaks down with 2,000 volts, but that in a 2,000-volt system as generally used, electromotive forces are occasionally generated amounting to 100,000 volts or more. These abnormal rises in electric pressure are chiefly due to the resonant effect, which has received so much attention of late years, and may be caused by the sudden breaking of the circuit of the dynamo. If these causes of excess be avoided, the electric pressure will never rise above the working pressure, and the insulation will never break down, even though its thickness be only little more than sufficient to stand a test at the working pressure. Dr. Fleming has shown us how to kill the resonant effect, and such a phenomenon never appears now at Deptford. This trouble may also be avoided by having as little capacity on the line as possible, especially when combined with low frequency. As to the cause of trouble mentioned above, I hold that it is a piece of culpable ignorance, ruinous to the machinery, if anyone should ever, on a large power circuit with alternating current, suddenly break the circuit while current is passing. This practice is quite unnecessary, and has given rise to a large proportion of the breakdowns of alternating current machinery.

PARALLEL WORKING.

Engineers in America have had no experience in actual commercial conditions of parallel working with alternators. This is partly because the machines which have been made in that country do not work so well as some others in parallel. In the case of the transmission from Niagara Falls, my opinion is that parallel working will give the best results. If this arrangement were not adopted, it is obvious that when the dynamos are loaded up as much as possible, they could never be all fully loaded. It is also quite obvious that if our conductors are to be carried through subways, the space required becomes quite excessive, unless we adopt parallel working. The complete success of parallel working between Tivoli and Rome left no doubt as to the feasibility, besides the desirability, of adopting parallel working. The reduction in frequency which we have made assists very considerably in this result, and it says much for the American manufacturer who has received the contract that, although parallel working with multiphase machines has not been adopted in the past, he is ready to guarantee the performance in this respect of the machines which are to be built for us.

The rules which govern the construction of machines which shall work well in parallel are not very clearly understood. The only fact which has been perfectly established in practice is, that the lower the frequency the more efficient and sure is the parallel working. It certainly depends to some extent upon the amount of self-induction and the amount of mechanical momentum in the machines. It is also certain that if the self-induction of the machines is too high, they will not work well in parallel. Of all machines which have been constructed, those which work the best in parallel appear to be those of Ganz & Company, Mordey, and Elwell-Parker, but there are many others which do extremely well. It is, at present, not possible to state exactly the conditions which are necessary, but I may say that, generally, a machine with a stiff magnetic field works better than one where the iron is far below magnetic saturation. In judging whether a machine of a particular type will or will not work in parallel, I think one must be generally guided largely by one's own personal experience in the matter, combined with a knowledge of the effects of self-induction, mechanical momentum, and magnetic saturation as deduced from theoretical considerations. I do not think that anyone who knows anything of the working of the Tivoli-Rome plant, would for a moment hesitate in saying that on a large and important station like that at Niagara Falls, parallel working is essential; and this is the opinion of Prof. Mengarini, who has so ably directed the works at Rome.

MOTORS.

Under this section it may be as well to discuss some of the different purposes for which the electric current will be required. With regard to arc and incandescent lighting, if the frequency be high enough, the current can be used directly for this purpose; although most people would prefer that, in the case of arc lighting, the current should be commutated or converted in some manner so as to give a continuous current. That this is unnecessary, however, is amply proved by the perfect success of the arc lighting by alternating currents in Rome and many other large cities, especially those which have been established by Messrs. Ganz & Company. At the present time one of the largest applications of electricity in the United States is for street railways, which require a continuous current. Another similar purpose which we shall have to consider is the application to canal boats, since it is intended to work the Erie canal by electricity. This canal starts from the Niagara River, and reaches the Hudson River at Albany, 350 miles distant. For these purposes some sort of commutator or motor transformer will be desirable. Some of the first work which will be done is the supply of much direct current at 150 volts for the production of aluminium. This also requires the continuous current, and similar means must be used for obtaining it. Among the large class of mills which will be established at Niagara Falls, one of the most important kind is wood-pulp mills, one of which is already working on our land, and will be the first to receive water-power from our canal. This type of mill uses many thousands of horse-power, and is worked continuously day and night. In this feature it resembles, probably, a large number of the mills which will take advantage of the cheap power at Niagara Falls. Such mills are working continuously day and night, and do not require to be ever stopped or reversed. This is an important class of work in our case, because current can be supplied to such mills by means of synchronizing alternators whose efficiency is extremely high, and this may perhaps be done in some cases without transformers. We require also to consider the case of small motors for use in shops, and for elevators, cranes, and a large number of other purposes. In this type of motor frequent stoppings and reversals are necessary. Hitherto direct current motors have generally been employed for this latter purpose, but the rotating phase induction motors are distinctly suitable, and when these have been fully developed they will probably be largely used for this purpose. The commutated current is a thing which is sure to be in common use before long, and although our arrangements at Niagara are perfectly complete without a machine for this purpose, still its employment has been considered by us, and the probability of its future use has influenced our judgment in some points. There are so many purposes for which the direct current is most convenient, that people would generally accept it for transmission if it were capable of being economically transformed up and down to different pressures. The direct current dynamo is really an alternating dynamo with a commutator placed upon it. If the commutator, instead of being placed there, be placed in the neighborhood of the motor, we obtain most of the advantages both of the continuous and of the alternating current. This is one of the advantages of having two phases generated by the dynamo, because it is much easier to rectify a two-phase current than a single phase current. In addition to the motors above specified, there are a large number of single phase motors which start with a powerful torque which have been invented by different electricians, but which are not yet put upon the market. There are also machines with commutators like a direct current dynamo with laminated field. These all become very efficient and useful when the frequency of alternations is sufficiently diminished.

(To be continued.)

Legal Notes.

Willard M. Taylor has been appointed receiver in supplementary proceedings for Arthur E. Hemmel, electrician, of New York City, in the suit of John Dunnican. Mr. Hemmel is at present manager of the A. E. Hemmel Electric Company.

John G. R. McCorkell, in answer to a suit against him by the Edison Electric Light Company, in Philadelphia, a few days ago, told the Court that his meter was not reliable and that he had been charged for electricity that he had not used, whereupon the company replied that the science was in its infancy, and that the meter was the best they could get, and the Court entered judgment in their favor for want of sufficient defence on the part of Mr. McCorkell.

John H. Wehrle, of Newark, claims that the electric conduit system, as recently put in operation in Washington, D. C., infringes materially upon letters-patent issued to him in 1890. He has secured counsel and proposes to test his rights.

Notice of attachment for $12,000 has been served on the North Attleboro, Mass., Steam and Electric Company and a keeper placed in charge. C. T. Guild is named as plaintiff. The writ is returnable in the Superior Court at Taunton in January.

The Lemaire Decorative and Electrical Manufacturing Company, of New York City, has made an assignment to Jamin S. Morse. It manufactured electric lamps and decorative metal work and equipped buildings with electrical apparatus. The company was incorporated in July, 1892, with a capital stock of $200,000, to push the invention of Paul Lemaire, who had been connected with the Edison General Electric Company. Warren A. Conover is the president and Nicholas H. Stavey treasurer. The liabilities of the company are believed to be less than $20,000.

The Supreme Court of Ohio has affirmed the decision of the Circuit Court of Lucas County in the suit of the Consolidated Street Railway and the Toledo Electric Street Railway Companies which was in favor of the latter. The dispute was about the right to use certain tracks of the Consolidated Company.

Application has been made to the Supreme Court by the Schlicting & Smith Company, manufacturers of electrical apparatus, Brooklyn, N. Y., for voluntary dissolution on the ground of insolvency. Judge Pratt, on the application of Isaac L. Miller, granted an order requiring all interested parties to show cause before Lawyer H. B. Hubbard, at 44 Court street, Brooklyn, on Feburary 26, why the corporation should not be dissolved.

Lamp Litigation.

The Novak Injunction Suit.

The case of the Edison Electric Light Company against the Waring Electric Company, manufacturers of the "Novak" incandescent lamp, was heard before Judge Shipman in the United States Court at Hartford on Saturday last.

Mr. Dyer, for plaintiffs, opened by reminding the court that the case about to be heard was part of the litigation that had been in progress for some time by which it was hoped to secure to the General Electric Company their rights as owners of the Edison patents on incandescent lamps.

Mr. W. E. Simonds, for the Waring Electric Company, addressed the court and said that the admission of plaintiffs' counsel just made, about the delay, proved, he thought, that the Edison Company was not entitled to secure an injunction. What had been said about the Perkins Lamp Company was unwarranted, inasmuch as the Novak lamp had been worked at and finally perfected by its inventor, Mr. John Waring, entirely unknown to the Perkins people.

He was not surprised to hear that the plaintiffs, when testing the lamps they had secured in such a questionable way, found no gas in them, for the very reason that they were not Novak but old Perkins lamps, sold them by an irresponsible party. In the Novak lamp gas was used in unmistakable quantity, and affidavits were in evidence to that effect made by gentlemen who were present when the lamps were being manufactured. They had the testimony of eminent professors proving the value of using bromine gas. He would not, however, go into that phase of the subject, but would argue the merits of the case itself.

Mr. Simonds then quoted from Judges Bradley and Wallace, in this country, who had heard some of the lamp cases that had already been passed upon, and alluded to the discoveries and inventions of Mr. Lane Fox in England, who was an authority on lamps. Judge Lacombe was also freely quoted, and statements were read from the various reports of cases.

Referring to the prior state of the art at the time Edison's patent was granted, it was shown that in a patent issued to Mr. Lane Fox in England there were found the combination of elements, including the carbon filament, an all-glass receiver, and a vacuum, which were included in Edison's patent. As a fact, Edison was not the inventor of the combination, and it had been proved that inventors cannot suppress improvements which are substantially identical. Edison is claimed to have succeeded in securing a stable carbon filament in a vacuum, which it was fair to presume was almost a perfect vacuum, for it was claimed that a slender filament of carbon may be maintained for an indefinite time. Had it been possible for electricians to construct a lamp possessing every element of durability no further improvement would have been needed; yet the impracticability of maintaining a carbon burner under such conditions was of importance. It had been asserted that the carbon was consumed unless there was a perfect vacuum to maintain its resistance. But nothing had been said about accluded gases being utilized for securing stability of the burner. The Edison patent requires that the vacuum shall be nearly perfect, and yet nothing had been said upon that point by the plaintiffs' counsel.

Quoting again from Judge Lacombe's paraphrase on the Edison patent, Mr. Simonds claimed that without doubt it meant an almost perfect vacuum, and such a vacuum cannot be produced by an ordinary mechanical plunger pump, such as was used in making the Novak lamp. The plaintiff contended that the Waring Company used a mercury pump, which was untrue, for they did not require a vacuum, and such statements proved that the plaintiffs knew nothing whatever about the Novak lamp or its manufacture.

Proceeding, Mr. Simonds contended that the Waring Electric Company had made an entirely new invention, altogether different from Edison's patent. The introduction of bromine gas was something entirely new and had never before been accomplished in the field of electrical science. The plaintiffs claim that we have got their invention and something in addition. We claim to have something they have not got.

The affidavits made by Prof. Robb of Trinity College, Prof. Wright of Yale, and Mr. Stone of Boston were then quoted from in support of Mr. Simonds's argument.

Mr. Clarence A. Seward, for the plaintiffs, then proceeded to review the points which had been submitted to the court. He claimed that the testimony that had been submitted by the defendants was that of interested parties in every case. It had further been stated that the defendants sold their lamps at a higher price than any one else. As a fact, his clients had been unable to discover that any Novak lamp had ever been sold beyond those purchased by the Edison Electric Company for the purposes of the present suit.

Mr. Seward supported his suggestion for an early decision, quoted authorities on the point, criticised some of the testimony adduced, dilated upon the technical features or principles involved, and concluded his argument by stating that high authorities showed that the court had the power, and it was its duty, to protect the rights of the parties to the suit.

Judge Shipman reserved his decision.

Obituary.

Mr. Henry Goebel, whose name has been prominently before the electrical fraternity the last twelve months, died of pneumonia at his home, 504 Sixth Ave., New York, on Tuesday last, December 4, after only a week's illness. It will be remembered that when the case of the Edison Electric Company vs. The Beacon Vacuum Pump and Electrical Company, for infringement, was heard before Judge Colt at Boston, last February, testimony, including numerous affidavits and several incandescent lamps, was presented in support of the claim that Mr. Goebel was the original inventor of the incandescent lamp and not Mr. Edison, who secured the patent therefor. Similar testimony was adduced at the subsequent trial of the case against the Columbia Incandescent Lamp Co. which took place in St. Louis. Mr. Goebel was a German by birth, his father being a well-known chocolate dealer at Springer in Germany. The deceased learned the trade of watchmaker and optician, devoting much time to the study of electricity and the making of batteries, dynamos, arc and incandescent lamps. About 1850 he created quite a sensation with his various apparatus, but being a man of retiring disposition, and never appreciating the value of money, he remained in obscurity, earning a comfortable livelihood and satisfied with the personal pleasure his discoveries and inventions afforded him. He had resided in this country since 1848, being the father of fourteen children, seven of whom survive him.

ELECTRICITY.

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR. - - 823 Monadnock Building

BOSTON:
W S. KEY, - Room 75, 320 Atlantic Avenue.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not ater than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

The Narragansett Station. The equipment of the Narragansett station, described elsewhere, includes two special machines which are the first of their kind in use, and which illustrate the tendency of modern practice towards large units. In the present case the installation of the machines is of too recent date to furnish any data as to their comparative merits, or even their practical efficiency, but the similarity of the two units is so close that it is hardly probable that there will be any considerable difference in their performance. Between these, however, and the smaller machines which compose the old plant, there must be found a great difference, not only in the actual efficiency, but in the simplification of their management and the wear and tear due to the high speed of the latter. On one side we have about 1,500 horse power developed by three machines, forming an integral part of the steam engines, which, on account of their slow speed of 90 revolutions, are largely exempt from the depreciation and repairs which a speed of 1,000 or 1,200 revolutions involves. They are also capable of running with but a trifle of attendance; and the absence of countershafting and belting is an advantage too obvious to call for explanation. If for no other reasons, the saving in space and the absence of noise will be found sufficient grounds for the use of direct-driven machines in many places.

On the other hand, a similar amount of power means the use of twenty or thirty machines whose speed occasions rapid depreciation and the care of which amounts to many times that needed for the former. The oiling, cleaning, adjusting of brushes, etc., and general inspection of the small machines takes half a day where the others need no more than half an hour.

Leaving out the gain in efficiency, therefore, the use of large direct-connected units commends itself strongly if only in respect to repairs and attendance. The series system of arc lighting in general use forbids the use of very large machines, but as the load in this case is practically constant, the advantage to be gained by substituting one or two generators for forty-seven in this case, could not be questioned. In multiple systems where the change is easily possible, there is little doubt that it will soon become the rule, as every consideration points to its advantage.

……o……

AMONG all the books which the Holiday Season calls forth, none can have fewer readers than the one which Mr. W. J. Johnston is about to issue, entitled, we believe, " Additional Arguments Showing that Messrs. Martin, Wetzler, Stump and Colvin are Base Conspirators, and that I am a Much Injured Man; or, Reasons Why the Trade Should Advertise Exclusively in My Pioneer Electrical Journal." The title is a long one, but wait till you see the book. The skeleton of Uriah Heep, done in gold, will illuminate the first cover, and the tail-piece will represent Mr. F. A. La Roche sinking into the bottomless pit—where Brother J. would like to see him.

Electricity in Agriculture. A bill has been introduced in Congress by Senator Peffer, providing for the establishment of an experimental station for testing the use of electric power for farm implements and machinery, to be under the supervision of the Secretary of Agriculture, and an appropriation of $10,000 is named for the first year's expenses in putting the plan into operation.

The value of experiments of this kind is not a matter of question to any one at all familiar with electrical work. As a means of propulsion for moving machinery such as ploughs, mowers, reapers, etc., electricity would hardly be more adaptable than a windmill or a sail. We may assume that a 500 volt current would be necessary, and very few farms are equipped with electric power stations. But even with the necessary current supply, how is it to be adapted to the machines? The trolley is evidently out of the question, as it is hardly feasible to cover a farm with trolley wires close enough for ploughing, and the storage battery is poorly adapted for running over ploughed ground. In view of the fact that steam engines have failed in this work principally on account of the high cost, electricity, even if it could be applied, would be a still more expensive failure.

For running stationary machinery, such as threshers, a motor may be readily used if the current is at hand, although a portable steam engine will probably be found very much cheaper.

The question is perfectly apparent in any particular case, to almost any electrician, and there is no more necessity for Government investigation of this subject than there is for a revision of the multiplication table.

……o……

THE LATEST reports from 44 Broad street are that Mr. Sunny has been brought up short and summarily dismissed, Mr. Garfield taking his place temporarily; and that the resignation of Mr. F. P. Fish is in the hands of the Board.

……o……

MR. HENRY S. HEWITT, who died in this city last week, of pneumonia, was a newspaper man of far more than ordinary ability and of varied experience. He had done much popular dramatic work, and was the author of the lines "It's English, You Know," which made Dixey famous. Latterly, Mr. Hewitt had devoted most of his time to Wall Street matters. His comments on General Electric in the *Daily America* and *Evening Advertiser* have attracted wide attention, and his views have been found correct.

……o……

THE REPAIR shops of the General Electric Company at Atlanta have been closed by order of the executive board of the corporation. This was one of the largest shops in the city and occupied a large five-story building. The entire South was included in the district served by the Atlanta shops. Repair work from every State in the South was sent there, and the shops figure extensively in Atlanta's industrial life. These facts are reported merely to show that the wreck of the General Electric Company is well nigh completed.

We note that the New York and London Electrical Association who sell "Actina" are advertising in the New York papers. We simply call the attention of our daily contemporaries to the fact that these people were branded as frauds and humbugs in these columns some months ago, and that subsequently they were ordered out of the Electricity Building at the Fair, where they had an exhibit.

……o……

It would be interesting to know just how much stock in the Vulcanized Fibre Company, of Wilmington, Del., is held by Mr. F. H. Webster, the purchasing agent of the General Electric Company, and just how and for what considerations Mr. Webster obtained the same. It would also be of interest to know how a man working on a modest salary, as is Mr. Webster, can build a row of houses out of the profits of a few brief years of business.

……o……

We do not wish to be considered as having any enmity whatever towards the Brush Electric Company of Cleveland; we merely record the progress of events, and point the moral that Mr. Coffin has controlled only to wreck. In confirmation of our previous reports on the condition of this company, we are enabled to state positively that the Brush Company's total business for the month of October amounted to less than $50,000.

……o……

No announcement made in these columns has given us more pleasure than it does to state that our old friend, everybody's friend, Mr. A. H. Reece, of Denver and the rest of the world, is the proud and happy father of a ten-pound son. At last accounts Achilles, Jr., was giving six concerts daily. No longer compelled to wear a title which has been a sham and a fraud—hail Papa Reece!

……o……

The stockholders of the Portland General Electric Company would do well to investigate the affairs of their company, and find out whether the dividend recently paid had been earned or was borrowed from the General Electric Company.

……o……

The late Mr. F. L. Ames was an investor to the amount of $300,000 in the preferred stock of the Northwest General Electric Company, recently collapsed. He who runs may read just why the Ames estate has closed out its holdings of General Electric at a sacrifice of more than fifty cents on the dollar of their original cost.

……o……

We are prepared to assure our readers that Mr. Coffin's scheme to interest local capital in Cleveland for the purchase of the Brush Company has been a flat failure. Mr. Coffin is about as well known in Cleveland as he is at the corner of Broad and Wall Streets.

……o……

We have plenty of evidence at our disposal to prove that the opinion of Mr. Coffin held by Messrs. Drexel, Morgan & Company is even lower than that held by Electricity.

It is an encouraging sign of improving conditions that the Stanley Electrical Manufacturing Company of Pittsfield have increased their capital stock to $200,000, the entire increase having been subscribed by local capitalists.

……o……

If Messrs. Coster and Twombly are really anxious to find all the rotten spots in the General Electric Company we beg to suggest the office of the purchasing agent as a good thing to investigate. Electricity can supply a few pointers on which to begin.

……o……

We wonder if Mr. H. M. Byllesby's record as the manager of the Northwest General Electric Company obtained for him the offer of the management of the Chicago office!

……o……

The new list price of the General Electric Company for Edison lamps is 65 cents, with 50 off to consumers in large lots and 60 off to licensees; that is, 32½ and 26 cents respectively.

What is the Scheme?

Is the Gutting of the Edisonian Enterprise to be Made Complete?

(From a Private Letter.)

The frequent and heavy shipments of machinery from the General Electric Company's factories at Lynn to Schenectady look for all the world like "house-flitting." Car after car heavily laden goes from Lynn to Schenectady every week. The suggestion that they are simply castings in the rough that have been made in the new foundry does not so satisfactorily explain the movement as does the more reasonable suggestion that, now the New York section of the Trust has got into control, they are making matters lively for the New England end of the line, and are simply centralizing the business at Schenectady, whither they are fast removing the machinery and some of the men to work it, away from the malarial, pestiferous exhalations that are supposed to rise from the marshes bordering on the Saugus River, Lynn, producing torpid livers and a chronic state of debility alike in workmen, directors and managers.

The remarks of our correspondent were interesting, and caused an immediate investigation.

The shipment of the machinery from Lynn to Schenectady was easily verified. But this machinery was far from being new castings. It was in reality worn out machinery from the Lynn works.

Further than this, we have learned that a considerable portion of the fine machines in the Schenectady works is offered for sale on the Boston market through a firm of brokers, Messrs. Hill, Clarke & Company, who are making sales as rapidly as possible.

The negotiations with Messrs. Hill, Clarke & Company have been conducted by Mr. F. H. Webster, the brilliant financier who holds the position of purchasing agent with the General Electric Company.

We understand that the Schenectady works are to be closed early next year, and the probability is that they will be offered for sale. The purchaser will perhaps find that what he has bought is not the outfit which has made up the finest electrical workshop on this side of the Atlantic.

There is in course of construction in the office of Manager Hawley, of the Hudson River Telephone Company at Albany, a novel map on which will be recorded the position of the house of each subscriber, of whom there are upwards of 1,600. The map has been traced on a scale of 400 feet to the inch, and is about four and one-half by five and three quarters feet in dimensions. The situation of each subscriber is indicated by a pin, and the metallic circuits for long distance instruments by a red silk thread.

The Signal for an Assault.

(From the Evening World.)

Stocks continued strong until the receipt of the following despatch from Boston:

"At a meeting of the General Electric Directors this morning the following resolution was adopted:

"*Whereas*, The net manufacturing profits since the last dividend, ordinarily applicable to payment of dividends, are offset by necessary shrinkage in customers' accounts and other assets.

"*Resolved*, That the cumulative dividends on the preferred stock be not declared at this time."

ehkeaicomtotky·or fl,upeP(o sgsreoitteto

This was the signal for an assault upon the entire market.

We do not know why this should have been construed as a signal for an assault on the market. Every broker in the Street should have considered it a signal for an assault on the office of the *Evening World*. We suppose, however, that the most conspicuous line in the above is merely a suggestion of what the preferred stockholders are supposed to have said.

Reorganization an Imperative Necessity.

(From the Boston Commercial Bulletin.)

The New York *Sun* and some other papers say that the latest movement of General Electric stock but adds another page to a mystery which has already deepened to an incomprehensible extent. Nonsense, there are those who could tell the story in its painful entirety, but pity induces silence. This column exposed the condition of the company months ago, and our duty has been performed. There is a point where duty ends, and persecution begins.

There is one man in the General Electric Company who has compelled the sincerest admiration for his grim, bull-dog tenacity in fighting what almost seemed inevitable. More than once have the largest holders had it explained to them that their only hope was in another contribution, as to attempt to unload in such a market meant a ramming of the stock to the ground. The conditions upon which such contributions were made are understood to have been that the stock would be so manipulated and supported as to allow of gradual liquidation, which has largely been accomplished.

We believe the statement to be misleading that the company is doing a business at the present time of $2,000,000 per annum net, and the annual meeting in January will probably prove it. It is needless to say that the combined companies never did a business of $8,000,000 in one year. The meeting in January of the company is likely to have many surprises in store for those who place implicit reliance in all the statements made recently concerning the affairs of the concern. Reorganization will then have become an imperative necessity.

Our contemporary takes a narrow view of the case. The duty of the financial press is not ended. It has scarcely begun. There is at least one important officer of the General Electric Company who knew in the beginning that the common stock was not worth 25 cents on the dollar, who knew that the essence of the whole combination scheme was a swindle and a fraud.

The plain duty of the press is to learn who among the Board of Directors were the swindlers, and who were the swindled, then to give the facts to the public.

The arch swindler, the shrewdest confidence man of the day, is still abroad, and looking for fresh victims.

Lectures on Electricity.

A course of lectures will be given in Philadelphia this winter, under the auspices of the electrical section of the Franklin Institute, as follows: December 19, "Thoughts on Cosmical Electricity," Prof. Elihu Thomson; December 26, "The Theory and Design of the Closed Coil Constant Current Arc Dynamo," Professor H. S. Carhart; February 27, 1894, "Telephony," J. J. Carty; April 24, "Magnetic and Dielectric Viscosity," Professor M. J. Pupin, and on June 26 a lecture on "Electro-Therapeutics," by Dr. William J. Morton, of New York City.

BOOK REVIEWS.

Standard Tables For Electric Wiremen. By Chas. M. Davis. Fourth Edition. Edited by W. D. Weaver. The W. J. Johnston Company. Flexible morocco. 128 pages. Price $1.00.

The third edition of this popular work was exhausted within a few months after its issue, and the fourth edition has been delayed in order that it might contain the latest revisions of the Insurance Rules of the Underwriters' International Electric Association, now almost exclusively used in the United States. In addition to the above rules there has been added to this edition an important section on the calculation of alternating current wiring which, for the first time, brings this subject within the reach of practical men.

A number of the most important tables were prepared expressly for this work, and are not to be found elsewhere.

The method of determining the sizes of conductors for incandescent wiring enables feeders, mains and branches to be proportioned as nearly exact as desired. The wiring formulas for motor circuits, etc., are put in a simple and practical form so as to be easily applied by any one. The formulas for horse power of engines and boilers, as published here for the first time, are based on rational principles, and the results they give are the actual commercial ratings, and not the theoretical horse power.

An Electrical Society at Cornell University.

The students interested in electrical science have lately organized at Cornell University an electrical society for the discussion of scientific problems. The membership is restricted to graduates and seniors, with a few of the oldest students in the other classes. The members of the faculty whose work has to do with electrical questions are honorary members. It is planned to hold meetings once a fortnight to be conducted in the same way as those of the American Institute of Electrical Engineers. The officers are as follows: President, E. B. Clark, '94; first vice president, J. Lyman, '94; second vice president, I. E. Macomber, '94; recording secretary, W. R. Turnbull, R. G.; corresponding secretary, R. W. Quick, '94; treasurer, B. S. Lamphear, '94; executive committee: Messrs. Clark and Turnbull ex officio, S. B. Fortenbaugh, M. A. Gerry and J. Lyman.

Current Items.

When an electric street railway was completed for public use in Bangkok, the capital of Siam, last year by Ohio capitalists, the Rev. J. M. Law, a medical missionary in Japan, thought that a similar enterprise would be profitable and of great public benefit in Tokio, the capital of the Japanese Empire, containing 1,400,000 persons. A few months ago he got Ohio capitalists to subscribe $100,000 to the scheme, with the assurance of additional capital after the plan was further advanced. Dr. Law then went to Japan, and, backed by the influence of American and other ambassadors, obtained one of the most liberal charters ever granted by Emperor Mutso Hita. The intention is to run a line from Tokio to Yokohama, a distance of thirty miles, and build a network of lines in both cities. J. W. Goss and Engineer Riblet have just sailed for Japan to inaugurate the scheme.

Cuero, Texas, was treated lately to an electrical display such as had never been seen or heard in that section. It began with distant thunder, getting closer rapidly, and in less than five minutes there were heavy peals of thunder and lightning flashes, and sparks or balls of fire descending within five feet of the ground and bursting, making a loud report. The people were all frightened, and are not anxious to have the same kind of a treat again.

Steam Piping and Efficiency of Steam Plants.

BY WILLIAM A. PIKE.*

In some recent experience with steam plants, the writer has been impressed with the apparent lack of good judgment and the application of correct principles in the arrangement of the piping between boilers and engines. In many cases, every effort seems to be made to select the best engines and boilers for the particular purpose in hand, but when it comes to the question of connecting them with steam pipes it would appear that it was thought that anything, with a hole through it, would do. Whether the piping is right or not, affects the economy, efficiency, and safety of a steam plant more than most engineers seem to think, and the writer believes that poorly contrived piping is in many cases as detrimental to high efficiency as the use of the wrong type of engine or boiler would be. The following are, perhaps, the points that should be most particularly looked out for in the design of a system of piping:

(1) The piping and accessories should be so arranged that practically dry steam shall always be delivered to the engine.

(2) The steam should reach the engine with very little "drop" in pressure.

(3) The piping should be so planned and valves so placed that water cannot under any circumstances collect anywhere, except in places especially arranged for that purpose.

(4) Wherever practicable, and especially where more than one engine is supplied from one battery of boilers, the piping and valves should be arranged so that in case of accident to any part it can be shut off without shutting down the whole plant.

These requirements are not offered as new or original, but simply as covering points often neglected, and as furnishing texts for this paper. The first requirement given above, viz., that the steam should reach the engine dry, is one often neglected, and the writer has in mind plants of considerable magnitude where absolutely no provision is made for drawing off condensed, or entertained, water, except through the engine itself, and the not uncommon cases of broken cylinder heads and pistons testify as to the effect of such designs. In these days of efficient pipe coverings, of separators, steam loops and traps, there is no excuse, but false economy, for allowing water to reach the engine. In connection with point No. 2, a plan for disposing of water, followed with good success, will be spoken of.

(2) Steam should reach the engine with but little drop in pressure. The effect that an improper arrangement of piping has on the pressure with which the steam reaches the engine, is probably not as well known as it should be, and the principal object of this paper is to bring it to the attention of engineers, and to show how in one case the evil has been remedied.

The conditions of the case used in illustration were as follows:

There were ten single acting engines, 16 x 27 x 16 inches, arranged on two sides of an engine room, and making 250 revolutions per minute. They were supplied by a number of boilers, and the steam from these first passed to a drum, 28 inches in diameter and 45 feet long, at the top of the boiler room and between two rows of boilers. From this drum separate 8-inch pipes ran to each of the five engines on the side nearest the boilers. (At the time referred to the other five were not connected.) The average length of each 8 inch pipe was about 76 feet, and there were five right-angle turns and two valves in each pipe.

On testing these engines it was found that there was a great difference between the boiler pressure and that at the engines.

This difference varied from eight to twenty pounds, depending on the amount of work being done, and averaged fourteen pounds, during usual work.

To find out, if possible, something as to the reason for this drop, an indicator was placed in connection with one of these 8-inch feed-pipes, just outside of the throttle-valve, which was close to the engine. At the same time cards were taken from the engine, and Fig. 1 represents the result.

The narrow diagram at the top is that taken from the pipe, while the lower one is a simultaneous diagram from the high-pressure cylinder.

As will be seen, the steam is at the pressure a at the beginning of the stroke, and at admission falls suddenly to b, then during admission keeps nearly constant until complete cut-off at c, then the pressure rises to d, and gradually settles down to a again at the beginning of a new revolution. From these diagrams it can be seen that, as there is practically no steam-chest to these engines, and as they are single acting and cutting off at about half stroke, there is a sudden and great demand on the 8-inch pipe during admission, a demand so great that the steam cannot keep up its pressure and, more than this, it appears that a vibration of the steam is set up in the pipe, causing the pressure to fluctuate from considerably below to somewhat above boiler pressure. This motion of the steam, of course, requires energy to be used up which is not therefore available for work in the engine.

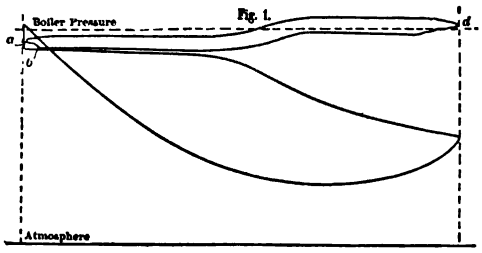

Fig. 1.

In attempting to account for this lost energy, the upper diagram has been treated as an ordinary indicator diagram, representing the work done in an 8-inch cylinder (the size of the pipe), and of a length equal to that of the volume of steam (in an 8-inch cylinder or pipe) required to supply the engine. Then, also, the loss due to friction is taken into account in the same way. The sum of these results is then compared with the extra work the steam would have done if admitted to the engine at boiler pressure. This last is shown in Fig. 2, in which the shaded part AB represents the additional work that would have been done if the steam had been at boiler pressure instead of having the admission line a-b, as was actually the case.

As an example, is taken the case of two diagrams, taken simultaneously on October 21, 1892, at 9:20 A. M.:

The area of the pipe diagram is 0.4 square inch; the length of the pipe diagram is 3.18 square inches; the mean effective pressure is 10.06 lbs.; and the length of an 8-inch cylinder, corresponding to the amount of steam used, is 3.0 feet. Then the work done $= Pe\,LAN =$ $10.06 \times 30 \times 50.26 \times 1 = 1{,}517$ ft.-lbs. The pressure loss, due to friction, is estimated, from the tables in "Steam," to be 2.19 lbs.; therefore the lost work due to friction $= 2.19 \times 50.26 \times 3.0 \times 1 = 330$ ft.-lbs., or a total of lost work = 1,847 ft.-lbs. The area added to the engine diagram, corresponding to AB, Fig. 2. = .28 square inch; the length of the whole diagram = 3.3 inches, and the lost mean effective pressure = 6.79 lbs. This pressure corresponds to 1,819 ft.-lbs. per stroke. Thus we find from the pipe diagram and the estimated friction a loss of 1,847 ft.-lbs., and the corresponding loss as figured by the engine diagram, 1,819 ft.-lbs., or an agreement within $1\frac{6}{10}$ per cent.

---

* Presented at the New York meeting of the American Society of Mechanical Engineers, December, 1893.

This analysis is added as an attempt to account for the loss, and whether correct or not, does not affect the fact that in this method of piping there is a serious loss of pressure, causing a corresponding decrease in efficiency.

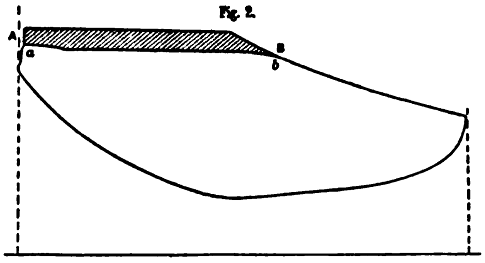

Fig. 2.

As in this case the "drop" was so great, it was considered desirable to endeavor to prevent it.

Two plans were suggested, as follows: First, when the amount of steam used was considered, it was seen that, due to the fact that the engines were single-acting, the demand while it lasted (with a cut-off of $\frac{1}{2}$, say $\frac{1}{4}$ of the time of a revolution) was excessive for an 8-inch pipe, though all the available data would show the pipe amply large for a uniform flow of that amount, and so the first idea was to enlarge the pipe, still piping separately to each engine, with the idea of reducing the effect of breakdowns. But the same reasoning led to the fact that an 8-inch pipe would be amply large if the flow could only be made practically uniform. This led to the second plan—viz., to place a reservoir for the steam close to the engine, and thus enable the flow through the 8-inch pipe to be more nearly uniform. In order to get information as to such a plan, the arrangement shown in Fig. 3 was extemporized.

The 8-inch pipe leading to engine No. 2 was cut, and a drum, 3 feet by 5 feet, put in close to the engine; from this drum a 10 inch pipe led to a 14-inch pipe, about 13 feet long, on the floor, and from this 8-inch pipes led to engines 1, 2, 3. The object was to get the effect, on drop of pressure, of receivers fed by one 8-inch pipe when supplying one, two or three engines. Much to the satisfaction of the experimenters, it was found that when engine No. 2 alone was supplied, through the drum, the drop was but a trifle over 1 lb.; that when two engines were fed the drop was a little over 2 lbs., and when all three were supplied by one 8-inch pipe, through the receivers, the drop was about 5 lbs. These results confirmed the theory that an 8-inch pipe was easily ample for two engines without excessive drop, and that when supplying three engines in this way, the drop was but little more than a third of that when but one engine was fed by a single 8-inch pipe without receivers.

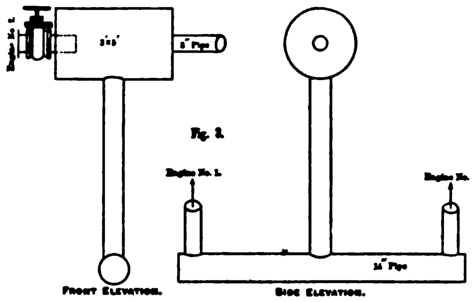

Fig. 3.

With this data as a basis new piping was designed for the plant, as follows: an extra drum was put in the boiler-room, and both drums connected with suitable valves to a loop of 8-inch pipe, running past each of the engines on the side nearest the boiler-room, with a drum, 3 feet x 5 feet, between this pipe and each of the engines. The nipples connecting the drums with the engines project about a foot into the receivers, as shown by the dotted lines in Fig. 3 to *a*, as separators for entrained water. Also each receiver was connected with a "steam loop," to carry this water back to the boilers. On the farther side a similar plan was followed, except that the loop was made of 10-inch pipe on account of the greater distance from the boilers. All pipes and drums were covered with an asbestos air-space covering, and valves were placed between each pair of engines to allow of shutting off any part in case of breakdown, without shutting down the rest of the plant. Tests made of this system show a drop of only 2 lbs. on the farther side of the engine-room, when all five engines were under full load and fed by one loop of 10-inch pipe (making a complete circuit from the drums back to the drums again). The combination of "steam loops" and the separator drums is the plan referred to under the heading with reference to dry steam. This has worked admirably, there being no signs of water in the engines as there had been before.

(3) The danger that may arise from having piping and valves so arranged that water can collect anywhere except in places specially provided, can be best shown by two cases within the knowledge of the writer.

A. A battery of boilers was connected with a header, as follows. From each of two boilers a short pipe was led up to a horizontal pipe branching to the right and left to another pipe leading to the header. Valves were placed close to each boiler, but none at the header. At one time two of these boilers were shut down and the valves at the boilers closed, the remainder of the battery being in service. The first thing noticed was that the calorimeter in the header showed much drier steam than there was any reason to expect, and on investigation it was found that the branch pipe between the two boilers and the header was acting as a condenser and separator, and becoming filled with water. This was fortunately noticed in time, and the water drawn off and a circulation kept up in the pipe, after which the calorimeter showed normal moisture and no harm was done; but if this body of water had been in any way set in motion the effect on the piping, which in this case was of cast iron, can be imagined.

B. In the second case there was a steam main leading from boilers to various pumps, engines, etc., and at a certain point a temporary pipe was led into this main from another boiler with no valve between the pipe and main. Steam was admitted to this pipe for some reason, and then after a few minutes shut off and steam let into the main. Shortly after this steam was again admitted to the temporary pipe, and very shortly a "slug" of water passed from this pipe to the main and acquiring a high velocity flew to a dead end and blew it off, causing the death of an employee. There seems no doubt that a valve placed at the intersection of the main and the temporary pipe, with a suitable "bleeder" in the pipe, would have prevented this accident if handled properly.

(4) The necessity of arranging piping so that in case of accident only a part of the plant need be shut down needs no argument, as the loss and annoyance due to shutting down a large plant, especially one on which the public in any way depends, as in the case of a lighting or street-railway plant, are much greater than the expense involved in making such a thing impossible. The system followed in the case cited under the second head is one that, while expensive, makes it impossible for any large part of the plant to need shutting down. The valves between the boilers and drums in the boiler room, combined with those in the pipes from the drums and those between the engines, making it possible to cut out almost any part without materially affecting the rest.

While, doubtless, much more could be written on this subject, it is hoped that the cases cited above will serve to call attention to the necessity for greater care in designing systems of piping, and will call out a fruitful discussion.

Personal.

Gilbert G. McDuff, who has represented the *Electrical World* and Directory work for the past year and seven months, has resigned and organized The American Electrical Publishing Company, and will publish the new paper, *Electrical and Street Railway Reporter*, with an office, 503 Electrical Exchange Building, New York.

Boston Notes.

There was an interesting meeting of the Lynn City Council, both branches, held last Tuesday evening, to consider an application from the Woodward Underground Electric Light and Cable Company, which is a local concern, for permission to open streets in order to lay, for demonstrating purposes, the conduits manufactured by this company, that the public might have opportunity of satisfying itself as to the merits of this conduit system. The petition was opposed by the Lynn Gas and Electric Company and the New England Telegraph and Telephone Company, whose counsel were present. Several electrical experts were examined as to the truth of the claims set up by the Woodward Company, and Professor Elihu Thomson's written testimony as to the value of the Woodward patents was read. The latter gave it as his opinion that the system possessed little, if any, merit, and the patents were of very slight value. The consensus of opinion was against granting the petition, and a little after midnight the subject was turned over to the city solicitor for his legal opinion thereupon

The Malden Board of Aldermen has at last granted the order giving the West End Street Railway Company permission to use electricity as a motive power for operating their cars in and around Malden. There has been some considerable delay about this matter and many conferences have been held between the company and aldermen. The order carries with it a condition that only a five cent fare shall be charged between any point in Malden and Scollay Square, Boston, and that the cars shall be running by January 1, 1894.

The course of twelve lectures on "Modern Uses of Electricity," given by Professor Charles R. Cross in the Massachusetts Institute of Technology, terminated on Thursday evening with a lecture on Telephony. The interest taken in these lectures had not only been sustained, but it had increased from first to last. They were unusually successful. Professor Puffer is now giving a course of twenty-four lectures at the Wells Memorial Hall on similar topics; these, too, are well attended and evoke much interest.

Judge Colt, of the United States Court, granted an order asked for by the General Electric Company against Captain A. de Khotinsky, restraining him from continuing to manufacture incandescent lamps in his factory at Marlboro, Mass., the same being, so the plaintiff claims, an infringement of the Edison patent now owned by the General Electric Company. The order was issued Friday, and will be operative until such time as an injunction may be applied for or granted.

The decision of Judge Colt in the suit of the General Electric Company vs. the Davis Electric Works, Springfield, Mass., is being looked for with much interest. The Davis Company simply repairs old lamps, and does a very large business of that kind. No new lamps are made, yet the Edison Company claims the Davis people are infringing their patents, hence the interest taken by outsiders.

Mr. H. W. Daggett, Jr., the enterprising and well-known president of the Interstate Electric Street Railway system, which runs through parts of Massachusetts and Rhode Island, has added yet another enterprise to his already long list of interests. He has recently purchased the plant, copyright, good will, etc., of the "Attleboro Daily Sun," a lively sheet published in a lively town. Mr. Daggett has always been successful in the electrical field, and we doubt not that he will make a success of his new journalistic enterprise. He is deservedly popular and full of public spirit.

The spasmodic show of a belligerent spirit that is being made just now by the deceasing General Electric Company in trying to secure a few more injunctions against makers of incandescent lamps, is being accurately appraised at its true worth. Those who have been closely watching the Trust's rapid descent, as well as those who are actually interested as stockholders, regard this new move as "The Song of the Dying Swan." We shall see. Lynn, the City of Shoes, is naturally much interested in the sad fate of the General Electric Company, by reason of the fact that for some time past between 4,000 and 5,000 hands were employed in the factories there, while to-day there are only a few hundred. Hence it is that some prominent Lynnites, holders of Electric stock, express the belief that the Trust will show a bold front when given reasonable time to recover from the effects of the fearful depression in general business affairs. About 200 hands have been discharged from the Lynn works since November 1. Before the consolidation with the Edison Company, the Thomson-Houston Company employed 3,000 hands in Lynn alone, and there the general opinion is that the greatest factor against the Trust is the alleged saddling of an $8,000,000 debt by the Edison Company upon the General Electric Company at the time of the consolidation. They maintain that the New York operators did a good job when the consolidation took place at the expense of the stockholders in the Thomson-Houston Company, which was believed by some to be in splendid condition at the time.

"The Black Crook," a brilliant spectacular piece, is having a long and unprecedentedly successful run at the Boston Theatre. At the close of its run it will be taken through the country at great expense. There are many very beautiful lighting effects and scenes in the piece, which are produced by electricity, and when traveling the company will carry with it the entire electrical output wherewith these weird effects are produced. For this purpose, new and unique apparatus is being manufactured by the W. S. Hill Electric Company, from designs made by Mr. Richard Cartwright, a well known electrical inventor and engineer, of Boston.

General News.

What is Going on in the Electrical World.

Worcester, Mass.—Horse cars no longer run in this city; all the street lines are now run by electricity.

Oil City, Pa.—Electric cars are now running regularly in the principal streets of the south side, the line having been opened on the 1st inst.

Tiffin, Ohio.—The Tiffin and Fostoria, the Tiffin Electric Railway, and the Tiffin Street Railway lines have consolidated; the new capital is $300,000.

Brooklyn, N. Y.—The Broadway Railroad Company has received permission from Mayor Boody to change its motive power from horses to the trolley system.

Augusta, Ga.—The electric exhibits were one of the best features of the local exposition, and the Augusta Electric Supply Company's display was particularly noteworthy.

Berkley, Va.—The *Citizen*, a local paper, is anxious for a little show of life in the town. It says: "Berkley is in need of a bank, electric lights, good streets and an electric car line."

Keokuk, Iowa.—The American Loan and Trust Company, owners of a controlling interest, have stopped the operation of the Keokuk Electric Railway, the receipts being less than the expenses.

New Brunswick, N. J.—The question of changing the motive power on the New Brunswick street car lines from horses to electricity is in the hands of the streets committee of common council with power to act.

Dayton, Ohio.—The City Railway Company is considering the adoption of electric motive power on its several branches, but has yet come to no definite determination. The trolley system, if any, will be the one selected.

Hillsboro, Ohio.—J. M. Hughey, receiver of the Hillsboro Gas and Electric Light Company, has been granted a franchise to maintain an electric plant and furnish arc and incandescent lights to the citizens for six months from the date of his acceptance.

Long Island City, N. Y.—The Steinway Railroad Company of Long Island City expects to have all its lines equipped with the trolley system by the first of next year. The splendid new power house erected on the Astoria shore at Hell Gate is about finished.

Elwood, Ind.—A natural gas explosion on November 29 demolished the plant of the electric light and street car company, and damaged a number of buildings. The accident left the city in darkness and without street car service. The loss is estimated at $15,000.

Kansas City, Mo.—The Interstate Telephone Company, composed of local capitalists, is actively engaged in arranging the necessary details for opening and operating a telephone exchange in this city. The franchise provides that for business houses $60 shall be charged and for residences $36 per annum.

Maumee, Ohio.—The council has extended the franchise once given to T. P. Brown, John Kumler and Coleman Keeler for an electric road within the corporate limits of the place until July 1. J. K. Tillotson is now in possession of the road, and says it is progressing rapidly.

Salt Lake City, Utah.—The Pioneer Electric Power Company, composed of residents of Utah, and with an alleged capital of a million dollars, has been established for the purpose of utilizing water from the Ogden River in the generation of electricity in sufficient force to supply this city with power to run machinery for factories, electric lights, street railroads, domestic heating and cooking, and such other purposes as can be effected by electric agencies.

Cleveland, Ohio.—The Cleveland Electric Railway Company is considering the suggestion to equip some of its cars appropriately for funeral purposes on the line leading by the Newbury Roman Catholic Cemetery. The undertakers favor the scheme as providing a means of reaching the burial place at much more reasonable cost than the usual $5 carriage ride.

Milwaukee, Wis.—The Milwaukee Electric Street Railway line has been sold to the Milwaukee Street Railway Company (Villard syndicate) and the transfer completed. The line was projected in 1886 as a cable line, but owing to the failure of the Rasmussen system was made an electric. From the prominent part taken by John A. Hinsey in securing the franchise for the road it came to be known as the Hinsey line.

McKeesport, Pa.—The trolley car has come into use here as a substitute for a hearse. The wife of a Wilmerding business man died last week, and the mourning husband decided to bury his dead in McKeesport. To get rid of a long, tedious and cold ride in carriages it was decided to use the trolley cars, and a car was fitted up to bear the coffin, accompanied by the pall-bearers. Behind this funeral car were six coaches, coupled together, and filled with the members of the family and their friends.

Montreal, Can.—The cars of the Montreal street railway are to be supplied with a new electric air brake, which is the invention of the electrical engineer of the company, and which is reported on trial to be very successful. The power to operate this brake, it appears, is generated by the motion of the wheels, and the faster the car is going the sooner it can be stopped. At the trial a car supplied with one of these brakes was allowed to attain a speed of twenty miles an hour, and was brought to a stop within a space of about four car lengths by the application of the electric brake.

New York.—The Commercial Cable Company has made a contract with Siemens Bros. & Co., of London, for the manufacture of a new cable, to be laid between Ireland and Nova Scotia. This cable, the third now owned by the company, will be 2,200 miles in length, and is to be made by specification insuring greater carrying capacity than any cable of the same length.—Corporation Counsel Clark has rendered an opinion to the effect that the employees of the Board of Electrical Control are subject to the New York Civil Service Boards.

Omaha, Neb.—For some months past there has been a quiet movement on foot to perfect the organization of a company to put in operation in this city a first-class electric lighting and power plant. The scheme has been to operate under the franchise of the old Northwestern Company which has the remnants of a plant located in the Woodman Building at Seventeenth and Nicholas streets. At the present time the rights under the franchise are being exercised by the New Omaha Thomson-Houston-Electric Light Company which has leased them from the owners.

Eau Claire, Wis.—A new company has been formed to operate the plant of the defunct National Electric Manufacturing Company, which went into the hands of a receiver and whose factory was bought by Peter Truax. The new corporation is called the National Electric Company. A. L. Ide, of Springfield, Ill., is president; Peter Truax, of Eau Claire, vice-president; W. E. Rusk, of Eau Claire, treasurer; Frank P. Ide, of Springfield, secretary. The paid up capital stock is $50,000. The property which passes into the hands of the new company cost the old company nearly $200,000.

Baltimore.—A deed has been recorded conveying from Messrs. Enoch Pratt, F. C. Latrobe and Robert Rennert, trustees, to the Wenstrom Electric Company all the property, rights and franchises of the Wenstrom Consolidated Dynamo and Motor Company in accordance with the plan for the reorganization of the company. The consideration mentioned in the deed is 5,000 shares of the full-paid capital stock of the Wenstrom Electric Company and $5.—The Brush Electric Light Company has decided to rebuild its works and put in a plant superior to that destroyed by fire. It is estimated that the cost of the improvements will be $300,000.

Washington, D. C.—The Lighthouse Board in its annual report gives interesting information respecting telephonic communications between lightships and the shore. The object is to more effectually succor vessels in distress. It is proposed as an experiment to first connect Monomoy Point Lighthouse, Massachusetts, with Pollock Rip Lightship, which are some four miles apart. Having done this the Board proposes next to connect two such stations much farther apart where the conditions of the bottom, current and approaches are different.—Senator Peffer introduced a bill in the Senate a few days ago which authorizes the Commissioners of the District to provide for lighting the public buildings and grounds of the city of Washington, and also for supplying light for citizens, by the establishment of an electric light plant of sufficient magnitude to supply all the light that may be needed by the Government and the people. It is provided that the work of constructing the plant shall be done on a contract let to the lowest bidder. The Commissioners of the District shall have the responsible management of the plant, and shall, on their own application, make the price of light at a uniform rate not to exceed 10 per cent above the actual cost of introduction and distribution. The 10 per cent. profit is to be paid annually into the Treasury of the United States to reimburse the Government for the money expended. The bill appropriates $1,000,000 for the establishment of the plant. It was referred to the Committee on the District of Columbia.

Canadian Notes.

Paris, Ont.—Messrs. Redher & McCosh will shortly let the contract for the erection of their new electro-plating factory.

Charlottetown, P. E. I.—The city council is considering the purchase of an electric light plant.

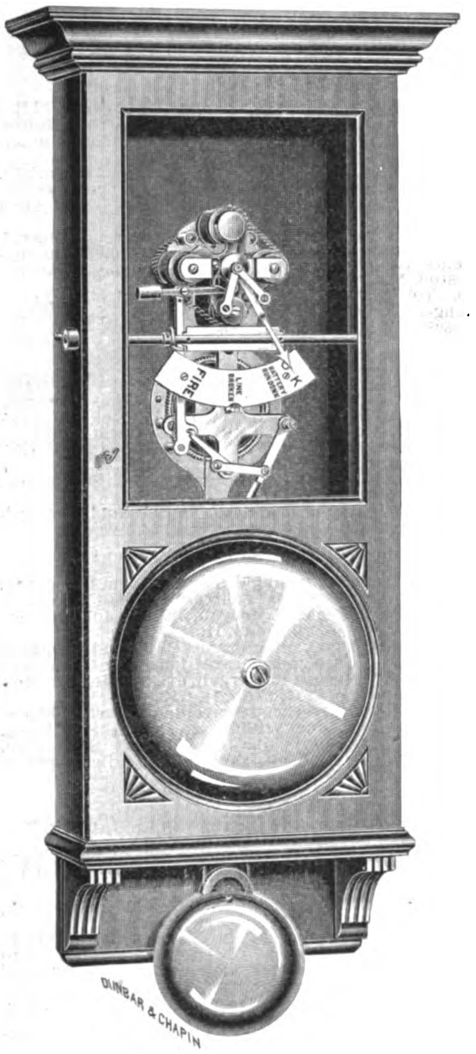
Montreal, Que.—The St. Jean-Baptiste Electric Light Company will erect a new power house adjoining their present works at the corner of Montana and Rachel streets.—The Bell Telephone Company contemplate the erection of an addition to their factory on Aqueduct street at an early date.

Victoria, B. C.—An electric railway to the Alberin mines will be built on China Creek and a smelter erected at the terminus.

Bedford, Que.—This town is considering an electric lighting scheme.

A New Automatic Fire Alarm System.

In the Fire Alarm systems heretofore used, although they appeared well on exhibition tests, serious faults have developed in regular practice, largely due to that class of troubles which appear only after such apparatus has been in use a considerable time. The wiring of such a system must necessarily extend all over a building to be protected, crossing and recrossing it many times, which makes it particularly liable to accident by broken lines and short circuits. The service is also such that the system must be certain to act without a moment's delay, and without any manual assistance whatever, even though it has stood for months without attention.



G. W. Brown's Fire Alarm Annunciator.

In consideration of the above, the following have been laid down as axioms:

First—Any system, to be entirely successful, must be of such a nature that any accident to the battery or wiring that will render the system inoperative will at once notify the attendant at the receiving station without sounding a fire alarm. In short, a system must watch itself and notify whenever it needs attention.

Second—It must be prompt and sure to act, and entirely unaffected by dust, insects, moisture, foul gases or jarring of the building, etc., and require no adjustments.

In the interests of economy such a system should require but very little current to operate it, and be easy and cheap to install.

The first axiom not only makes it necessary that the system shall be closed circuit, but that the entire current required to give the alarm shall flow all the time, otherwise the extra batteries and lines intended to be brought into action by the thermostat may not be operative.

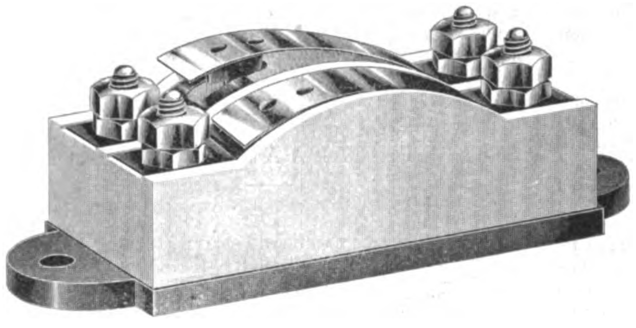
In the system in question, by very simple mechanism, the thermostat in acting reverses the current instead of simply stopping it. Reversing the current is a change which never occurs by accident; hence the receiving instrument will never indicate fire unless a thermostat has acted. The receiving mechanism consists of a very simple and reliable electro-mechanical gong, controlled by a polarized armature of the rotary type, to which is attached a pointer moving over a suitable dial arranged to show just what change has occurred in the line. This dial is marked "O. K." on its right hand end, below which are the words "Battery Run Down," in the middle "Line Broke," and on the left hand end "Fire."

A very important feature of this apparatus is the fact that the battery current can rise much above or fall much below the normal without affecting the working of the system. This system can be arranged with two bells, one of about eight inch in the engine house to ring for fire only, the other of small size to call attention to trouble with the line. A large striker is also provided to strike a factory or other large bell, one blow to indicate trouble with the line, and continuous ringing to indicate fire. This is important in places where firemen are not on duty at all times.

One of the most important features of an Automatic Fire Alarm is the thermostat, upon which to a large degree the efficiency of the system depends. The one here illustrated has been the subject of a great deal of study and experimenting, and is believed to embody more good features than any other ever devised, and no bad ones. Its construction and operation are as follows:

Upon the lower side of a porcelain base are clamped two flat bronze springs, which are held under tension by a fusible solder, the melting point of which can be changed to suit different positions. To the upper side of this base is clamped a plate of vulcanized fibre, through which screws pass into the ceiling to fasten the thermostat in position. In the centre of the porcelain base and covered by the fibre plate is moulded a cavity which contains electro-plated contact points brought into action by releasing the springs. These contact points are punched from sheet brass and riveted to the bronze springs, extending through the porcelain into the cavity referred to, and so arranged as to press against suitable electro-plated copper strips connected in such a way as to reverse the current when the springs are released by melting the solder. The working parts of this thermostat are entirely protected from dust and insects, causes which render a large percentage of those now in use entirely inoperative after they have been in place a year or two. The part sensitive to heat is entirely uncovered and in the best possible position to be affected by direct rays as well as the heated air from a fire, and being thin acts promptly, and will never change its adjustment.

In case the battery should be allowed to run down, the armature would be drawn towards its central position by the weight until the hand pointed to "Battery Run Down," when the striking mechanism would be unlocked and the bell strike. The attendant, on looking at the dial, would see that the bell is striking because the battery is run down, and to silence the bell turns over the handle on the left hand side of the case, which, besides stopping the striker, turns up a card over the dial, marked "Disconnected," which shows that the system is inoperative. Even under these conditions, the system will sound an alarm in case a fire should occur, unless allowed to stand too long. In case of a broken line or short circuit (which in this case is equivalent to a broken line), the same thing takes place, excepting that the pointer indicates "Line Broken." In this case, when the line is repaired, the bell again strikes to notify the attendant that the line has been repaired, and the hand points again to "O. K.," the bell being silenced by turning the lever and card back to the original position. In case of fire the bell rings, and the pointer is carried to the word "Fire," and locked in that position where it remains until released by the attendant.



G. W. Brown's Thermostat.

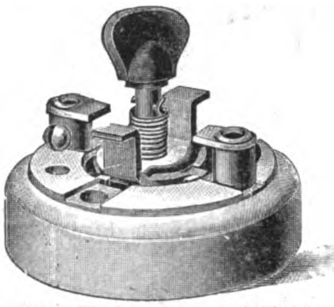
It will be seen that this system is entirely free from relays and local circuits, which in practice have been found to be unreliable. In the arrangement of the annunciator and public alarm bell, with which this system is provided, no element is introduced that can possibly interfere with the action of the engine house gong, bearing in mind that the action of this bell is by far the most important function of the system. With this in view, care has been taken that its action should not depend upon anything delicate or uncertain, or be in any way interfered with by the failure of the other instruments.

It was designed by Mr. Gilman W. Brown, of West Newbury, Mass., who has devoted the last four years to perfecting its details, and is fully protected by patents.

Metropolitan Electric Company.

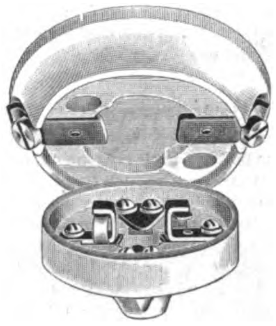
The Metropolitan Electric Company, offices 522-523 Monadnock Building, Chicago, have secured the entire output of H. T. Paiste's factory and hereafter will market exclusively these specialties.

A visit made to the factory enabled us to see these various articles manufactured step by step until completed. First in importance was the making of Eccentric Switches. These switches are the result of years of earnest thought and experience on the part of Mr. Paiste, the pioneer switch maker. An important feature in the switch, as shown in the cut, is that all the brass parts are fixed firmly to the porcelain without the use of screws. In porcelain there is no "cushion," hence screws will sooner or later jar out. The movement is of the eccentric order, thus insuring a positive mechanical action. The electrical contact is made by solder contacts. We witnessed a test made on a five ampere switch. This switch had been run for four days, making thirty breaks and makes, all told about 70,000 half revolutions per minute, more than a switch would be used in fifty years. It was carrying a load of twenty-five amperes at that time, and did it without heating the contact parts. The breaking capacity will easily break 500 volts. These switches are made single and double pole, also three-way.

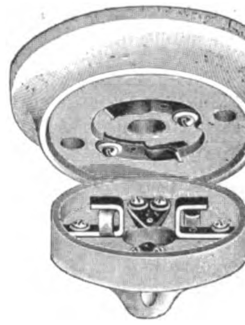


Metropolitan Electric Company's Paiste Switch.

We next visited the Cut-Out department. Here is made in large quantities the Paiste Ceiling Cut-Out (Schaffer style) for open and concealed work. The attached cuts will readily demonstrate the simplicity and beauty of their design. Those of our readers who visited the Electricity Building at the World's Fair will remember the very neat and artistic design made exclusively by these Cut-Outs in Mr. Paiste's exhibit. Main and Branch Cut-Outs of the S. M. and Edison style are also made in large quantities. A new covered branch and main has just been manufactured that will be much appreciated by the electrical trade. A covered Horse-Shoe Cut-Out is in process of manufacture and will be ready to deliver in a short time.

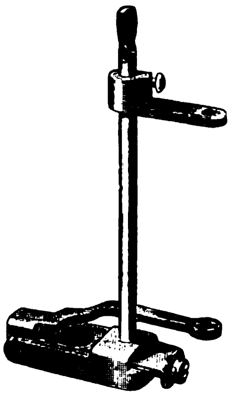


Metropolitan Electric Company's Cut-Out.



Metropolitan Electric Company's Cut-Out.

We next visited the Stamping Department, and there saw them making out of flat sheet metal a clutch for T.-H. arc lamps. The attached cut will illustrate the design and movement. The peculiar feature of this specialty is that it can be adjusted to a carbon rod and therefore is practically indestructible. German silver contacts are used throughout. Here also is made an adjustable lower con-

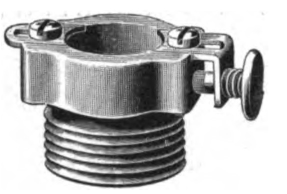


Metropolitan Electric Company's Clutch.

tact bushing for T.-H. arc lamps; the cut will easily illustrate the simplicity of the device.

Numerous screw machines were running, turning out binding posts and various other articles.

Another department just being organized is the making of switchboards, etc. Here men were busy making a complete set of switch and cut-out boards for the Ryerson Library.



Metropolitan Electric Company's Contact Bushing.

The Electric Appliance Company's New Catalogue.

The Electric Appliance Company, of Chicago, have just received from the press their new catalogue of general electrical supplies, which they are sending out to their friends and customers. The catalogue contains 334 pages, and is well printed on heavy book paper. Although concerning nearly the entire field of electrical goods it is very compact and convenient as a reference. Especial attention has been paid to the point of listing only such articles as are reliable and standard. A careful examination of the pages of the Appliance Company's catalogue will be well repaid in time and money saved.

"Acme" Portable Testing Set, "Style B."

Queen & Company, Incorporated, Philadelphia, are now bringing out "Style B" of their "Acme" Engineering Set, which must surely meet with much favor. It is completely self-contained, comprising bridge, rheostat, D'Arsonval galvanometer, battery and keys, all mounted in a highly finished mahogany box, 3¼ x 5¾ x 5 inches, that weighs less than six pounds ready for use. The extreme portability of the apparatus and the fact that rapid measurements can be made under conditions that do not admit of another type of galvanometer being employed, recommend the set to the careful consideration of intending buyers.

Descriptive circular No. 445 will be mailed free upon request to the makers.

COMMERCIAL PARAGRAPHS.

Messrs. Elson & Brewster, New York agents for the W. S. Hill Electric Company of Boston, have removed their offices to No. 141 Liberty street, Central Building.

The Metropolitan Electric Company, of Chicago, are gathering together a very important line of electric railway devices, prominent among which are the Standard Paint Company's P. & B. specialties, the "Anti-Thunderbolt" Oil Paper, Special Oil Glass Insulators, N. I. R. Feed Wire, etc.

The Texas Electric Brokerage Company inform us by circular that they have opened an electrical brokerage business in Dallas and will extend it throughout the State of Texas and adjoining territories. They will sell goods as manufacturers' agents at manufacturers' or wholesale dealers' prices, and will procure orders and place them with the dealer, who may ship direct to the purchaser, he merely notifying the brokerage company whether he fills or refuses to fill the order, and sending a statement of goods sold through their efforts at the end of each month or within ten days thereafter, enclosing a check for amount of commissions due for the month. The Brokerage Company will cheerfully correspond with manufacturers and dealers in regard to such arrangements as they are prepared to enter into. Address: Texas Electric Brokerage Company, North Texas National Bank Building, Dallas, Texas.

The Geo. E. Carter Company has recently been organized, with offices at 1,563 Monadnock Building, Chicago, for the purpose of handling a number of high grade electrical specialties. The company is composed of Mr. Geo. Carter, who has occupied the position of city salesman with the Ansonia Electrical Company, and Geo. S. Thayer, recently connected with the Westinghouse Company. The new concern has been appointed exclusive selling agents of the American Carbon Company's products. They will also handle the Helios arc lamp, the Pumpelly-Sorley storage battery and the Hattery feed water heater. The company expect to add a number of new specialties in the near future.

Goodhue & Lincoln is the title of a new firm which is about to enter the electrical specialty field in Chicago, Mr. Wells Goodhue, formerly with the Ansonia Electric Company and until recently the vice-president of the firm of Taylor, Goodhue & Ames, and Mr. Henry Lincoln, of Boston, are the moving spirits in the new company. Their specialties are high grade electrical material, which includes Wagner Transformers, Motors and Dynamos, and Sunbeam Incandescent Lamps. The new company starts out with good prospects and will undoubtedly be heard from in the near future.

INCORPORATIONS.

Leffler Electro-Magnetic Railway Company, Chicago. Capital stock, $1,000.000. Incorporators: P. W. Leffler, W. T. Pratt and James Brady.

The Canonsburg Electric Light, Heat and Power Company, at Harrisburg, Pa. Capital stock, $12,000.

The Indianapolis and Broad Ripple Suburban Railroad Company, Indianapolis. Capital stock, $50,000. Directors: R. T. McDonald, R. W. Clay, Sterling R. Holt, R. C. Light, Leon Bailey, Thomas Taggart and A. G. Smith.

The Blair Lamp Adjuster Company, Omaha, Neb.—to establish a general electrical supply house, doing a wholesale and retail business; a specialty will be made of the manufacture of electric drop light hangers. Capital stock, $50,000. Promoters: W. J. C. Putnam Cramer, H. F. Roberson and Will Whitmore.

The Carroll Electric Company, Fishkill, N. Y.—to produce electricity for light, heat and power. Capital stock, $100,000. Promoters: Wm. Carroll, New York City; Chas. H. Watson, Fishkill-on-Hudson, N. Y.; Wm. Burtenshaw, Brooklyn, N. Y.

The Standard Thermometer Company, Peabody, Mass.—to manufacture and sell thermometers and electrical and other mechanical appliances. Capital stock, $125,000. Promoters: Henry G. Rice, Samuel C. Lord, Edgar W. Upton, Herbert Torrey, Francis R. Upton.

The Princeton Light and Power Company, Princeton, Ind.—to furnish light by means of electricity, natural or manufactured gas or other means, and to furnish motive power for the purpose of propelling any and all kinds of machinery and conveyances for passengers and freight. Capital stock, $25,000. Promoters: Robt. N. Parrett, Louis Rothschild, Arthur P. Twineham.

The Homestead Street Railway Company, Beaver, Pa.—to construct and operate an electric railway from 30th street, Pittsburg, to Homestead, Allegheny County, Pa. Capital stock, $30,000. Promoters Cyrus A. Danals, Thomas H. Javens, Henry M. Camp.

The Thompson Electric Company, Wheeling, W. Va.—to construct, purchase, sell and operate electrical dynamos, motors, etc. Capital stock, $25,000. Promoters: C. H. Thompson, G. W. Thompson, J. H. Griffith, all of Marins Ferry, Ohio.

The American Standard Battery Company (incorporated in W. Va.), New York City—to purchase, lease and deal in patent rights applicable to primary and other electric batteries, dynamos, etc. Capital stock, $100,000. Promoters: C. T. Griffiths, M. H. Rutty, Jas. W. Garson, all of New York City.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED NOVEMBER 28, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

509,403. Electric Closed-Conduit System for Railways. George W. von Siemens, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 13, 1892.

509,421. Conduit Electric Railway. Adolph Worner, Buda-Pesth, Austria-Hungary, assignor to Siemens & Halske, Berlin, Germany. Filed Nov. 12, 1891.

509,518. Electric Railway. Thomas A. Edison, Llewellyn Park, N. J. Filed Aug. 14, 1891. Renewed June 2, 1893.

509,603. Coupling for Electric Conduits. Augustus Noll, New York, N. Y., assignor to Sigmund Bergmann, same place. Filed Aug. 5, 1892.

509,616. Clamp-Ear for Trolley-Wires. Edwin B. Gates, Decatur, Ill., assignor of one-half to Don Carlos Shaw, same place. Filed April 5, 1893.

509,622. Conduit Electric Railway. Edward H. Johnson, New York, N. Y. Filed May 16, 1892.

509,650. Trolley-Track. William H. Brodie, Brooklyn, N. Y. Filed Sept. 2, 1893.

509,651. Closed-Conduit System for Electric Railways. Emile Chabeault, Marseilles, France. Filed Oct. 13, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

509,443. Electric-Lighting System. James B. McGiffert, Elizabeth, N. J. Filed March 24, 1893.

509,842. Electric-Arc Lamp. Ernest P. Clark, New York, N. Y., assignor to the Clark Electric Company of New York. Filed Jan. 28, 1893.

DYNAMOS, MOTORS, ETC.

509,445. Combined Electric Motor and Induction-Coil. John S. Nowotny, Cincinnati, Ohio. Filed April 5, 1890.

509,475. Compounding Dynamo-Electric Machines. Walter H. Knight, Lynn., assignor to the General Electric Company, Boston, Mass. Filed Feb. 6, 1893.

509,486. Compounding Dynamo-Electric Machines. Horace F. Parshall, Lynn, assignor to the General Electric Company, Boston, Mass. Filed May 11, 1893.

509,499. Regulator for Dynamo-Electric Machines. Elihu Thomson, Swampscott, Mass., assignor to the Thomson-Houston Electric Company of Connecticut. Filed April 11, 1892.

509,505. Switching Apparatus for Electric Motors. Parvin Wright and Joseph W. Kinsey, Denver, Colo. Filed Nov. 15, 1892.

509,517. System of Electrical Distribution. Thomas A. Edison, Menlo Park, N. J. Filed Dec. 12, 1883.

509,620. Shaft-Mount for Armatures. Samuel E. Hitt, Rockford, assignor, by mesne assignments, of one-half to W. Irving Hitt, Chicago, Ill. Filed March 20, 1893.

509,662. Dynamo-Electric Machine. Carl Hoffman, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Feb. 28, 1893.

509,705. Electro-Magnetic Reciprocating Motor. Richard Threfall, Sydney, New South Wales. Filed Feb. 24, 1892.

BATTERIES.

509,881. Battery-Box and Case. Linwood F. Jordan, Somerville, Mass., assignor of one-half to Henry B. Bennett, Portland, Me. Filed Oct. 3, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

509,480. Printing-Telegraph. Robert A. Fowden, Philadelphia, Pa., assignor to the International Printing Telegraph Company, Camden, N. J. Filed Jan. 31, 1893.

509,477. Trunk-Line Signal. Edmund S. C. May, Chicago, Ill., assignor, by mesne assignments, to the American Bell Telephone Company, Boston, Mass. Filed April 17, 1893.

509,484. Signal Apparatus for Telephone Systems. Joseph J. O'Connell, Chicago, Ill., assignor, by mesne assignments, to the American Bell Telephone Company, Boston, Mass. Filed April 17, 1893.

509,530. Telephonic Apparatus. William S. Harrison, Hong-Kong, China. Filed Dec. 13, 1892. Renewed Oct. 5, 1893.

ALARM AND SIGNALING APPARATUS.

509,367. Switchboard Circuit and Signaling Apparatus. Francis W. Dunbar and Edmund S. C. May, Newark, N. J., assignors to the American Telephone and Telegraph Company of New York. Filed March 7, 1892.

509,524. Police and Fire Alarm System. James B. Gill, San Francisco, Cal. Filed Dec. 9, 1892.

509,545. Signal Apparatus. George McIntosh, Stonington, Conn. Filed Feb. 1, 1893.

509,680. Electro Magnetic Alarm. Parnell Rabbidge, Sydney, New South Wales. Filed Feb. 28, 1893.

ELECTRICALLY OPERATED TRAVELLING CRANES.

509,756. Overhead Travelling Crane. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan, Sr., Thomas R. Morgan, Jr., and John R. Morgan, same place. Filed Jan. 11, 1893.

509,757. Overhead Travelling Crane. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan, Sr., Thomas R. Morgan, Jr., and John R. Morgan, same place. Filed Jan. 14, 1893.

509,758. Trolley for Overhead Travelling Cranes. Thomas R. Morgan, Sr., and William H. Morgan, Alliance, Ohio, assignors of one-half to Thomas R. Morgan, Jr., and John R. Morgan, same place. Filed April 8, 1893.

MISCELLANEOUS.

509,363. Electric Current Regulator. John H. Clark, Boston, Mass. Filed Dec. 30, 1891.

509,373. Electrically Operated Jumper Drill. Carl Hoffmann, Berlin, Germany, assignor to Siemens & Halske, same place. Filed Oct. 12, 1891.

509,397. Electric Elevator. Charles R. Pratt, New York, N. Y. Filed Feb. 5, 1892.

509,500. Electric Double Pole Fixture Cut-Out. Henry E. Werline, Lancaster, Pa., assignor of three-fourths to Frank S. Barr, same place, and Edwin L. Reinhold and Henry B. Cassel, Marietta, Pa. Filed Feb. 15, 1893.

509,501. Electric Pendant Cut-Out. Henry E. Werline, Lancaster, Pa., assignor of three-fourths to Edwin L. Reinhold and Henry Burd Cassel, Marietta, and Frank S. Barr, Lancaster, Pa. Filed April 17, 1893.

509,539. Electric Switch. Charles J. Klein, New York, N. Y. Filed Dec. 2, 1892.

509,556. Electric Plow. Charles H. Roberts, Eau Claire, Wis. Filed April 30, 1892.

509,578. Potential Indicator. George A. Lintner, Minneapolis, Minn. Filed March 16, 1893.

509,614. Strain Insulator. Charles H. Dey, Boston, Mass., assignor to Albert & J. M. Anderson, same place. Filed June 5, 1893.

509,634. Process of Refining Slimes from the Electrolytic Refining of Copper. David K. Tuttle, Philadelphia, Pa., and Cabell Whitehead, Washington, D. C. Original application filed Feb. 20, 1892. Divided and this application filed Sept. 19, 1893.

509,713. Cut-Out. Nathaniel F. Adams, Boston, assignor of one-half to John G. Robinson, Melrose, and Hayes Lougee, Newton, Mass. Filed Feb. 18, 1893.

509,750. Electric Current Meter. William T. M. Mottram, Dallas, Tex. Filed May 23, 1891.

509,770. Laminated Converter Core. Charles F. Scott, Pittsburg, Pa. Filed Nov. 25. 1892.

509.776. Electrical Controller. Elmer A. Sperry, Cleveland, Ohio. Filed Aug. 21, 1893.

509,783. Lightning Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed May 16, 1893.

509,784. Universal Non-Arcing Lightning Arrester. Alexander Wurts, Pittsburg, Pa., assignor to the Westinghouse Electric and Manufacturing Company, same place. Filed May 16, 1893.

509,821. Electric Elevator. Francis B. Perkins, Boston, Mass. Filed March 16, 1889.

To Inventors and Others.

United States and Foreign Patents Procured.

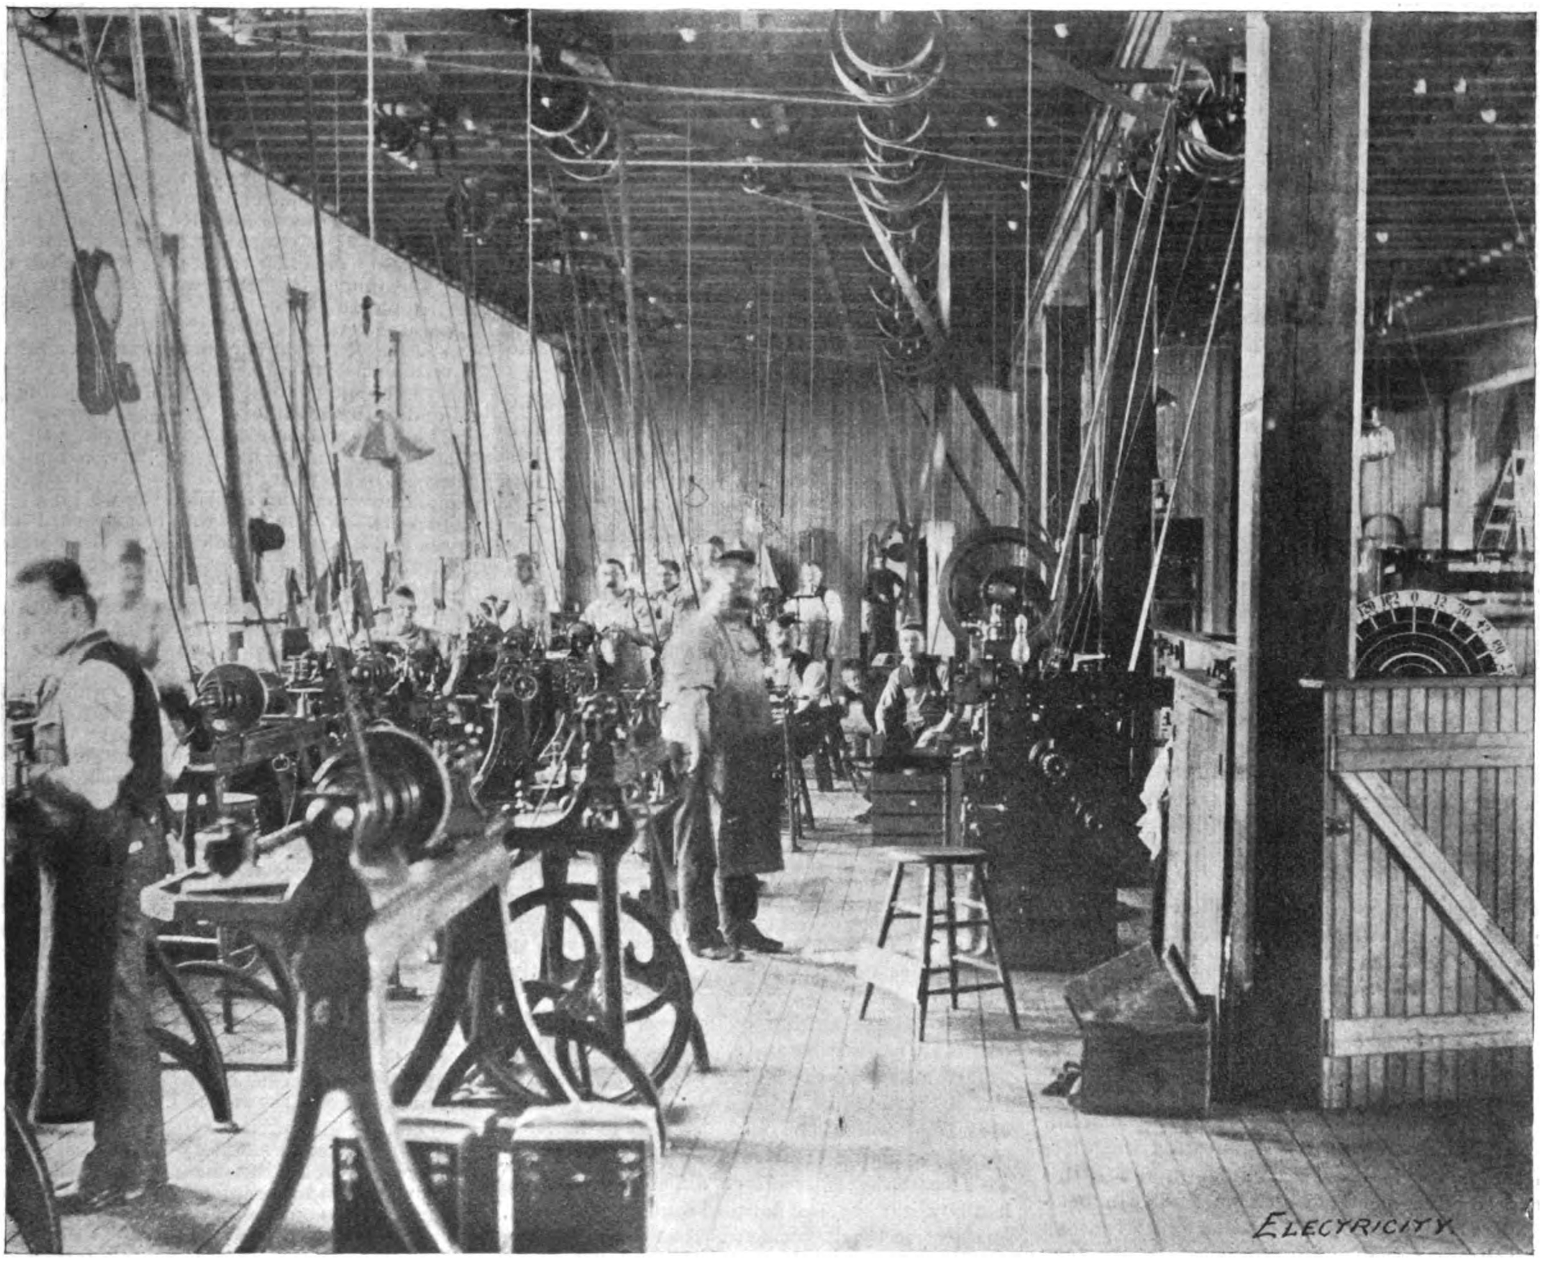
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. DECEMBER 20, 1893. CHICAGO. No. 23



MACHINE SHOP, J. C. VETTER & COMPANY, NEW YORK. (SEE PAGE 277.)

Recollections of Werner Von Siemens.*

IV.—Telegraph Work in 1848.

In the meantime great changes had taken place there (in Berlin). The military commission for the introduction of electric telegraphs had been formally dissolved and telegraphy placed under the newly created Ministry of Commerce. As head of this department Assessor Nottebohm had been appointed, who had already occupied an administrative post in the telegraph commission. The resolution was taken to follow the course adopted by the late commission, and first to construct in all haste a subterranean line from Berlin to Frankfort-on-the-Main, where the German National Assembly was holding its sittings. In consequence of this, an inquiry was addressed to me whether I was disposed to direct the construction of this line according to the proposals made by me to the commission. In the event of my acceptance my command from the War-Office would be transferred to the Ministry of Commerce. Although a position under Assessor Nottebohm was not particularly agreeable to me, I nevertheless accepted the call, since it set me free from the present monotonous military life in the little fort, and gave me an opportunity of bringing my proposals into practical execution on a large scale.

In Berlin I found Halske already busily engaged in work for the line about to be constructed. It had been determined to lay the line altogether underground, as it was feared that above-ground wires would be destroyed in that time of great political excitement. The wires, insulated by a coating of gutta-percha, were to be laid without external protection in a trench a foot and a half deep in the railway embankment. My proposed protection of the communications by means of envelopes of iron wires, iron tubes, or clay channels was not approved on account of the great expense. A contract had already been signed with the Berlin indiarubber factory of Fonrobert & Pruckner for the further construction of subterranean wires. This was the same factory to which I had transferred my model for the covering of copper wires with gutta-percha, and which had already manufactured the experimental line from Berlin to Grossbeeren with a press made according to that model. I had to confine myself to providing for the best possible insulation of the wires. Considerable difficulties stood in the way however, inasmuch as, owing to the sudden great demand for gutta-percha, the best insulation sort was soon out of the market.

To cope with this impediment to the rapid progress required of the work it was resolved to make use of the recent English invention of vulcanizing the gutta-percha, i. e., intimately mixing it with sulphur, whereby even with inferior kinds of gutta-percha the insulation of the conductors as well as their power of resisting external injuries was increased. Unfortunately the vulcanization turned out afterwards a mistake, as the sulphur combined with the copper of the conductor and thereby also the adjacent layers of gutta-percha became gradually copper and capable of conduction. To this circumstance it was mainly ascribable that the wires, though perfectly insulated at the time of their being laid down, had after a few months already lost a part of their insulation.

Particular care was taken in testing the wires in the factory. Halske manufactured for this purpose galvanometers which far excelled in sensitiveness all known up to that time. In testings with these sensitive galvanometers I observed for the first time in the year 1847 the surprising phenomenon that, even in a perfectly insulated wire lying in water, on interposing a battery a short current occurred, which was succeeded on removal of the battery by an equally strong current in the opposite direction. This was the first observation of the electrostatic charge by galvanic chains. I was at first inclined to see in this a phenomenon of polarization, since at that time the galvanometer was not considered capable of indicating the passage of static electricity. The phenomena on longer well insulated lines soon however rendered it quite indubitable to me that it was a case of electrostatic charge and not of polarization.

The first difficulty, the finding defective insulating points in a long piece of the conducting wire, I was able to overcome in the following manner. The dry wire coated with gutta-percha was drawn through a vessel filled with water and insulated in respect to the earth, whilst the second coil of thin covered wire, which surrounded the electromagnet of a Neef hammer, was interposed between the insulated copper wire and the earth. If now a workman standing in communication with the earth dipped a finger into the water of the insulated vessel, he felt electrical shocks at the moment at which a defective piece of the wire enveloped by gutta-percha was immersed. In this way I succeeded in detecting all the small defects of insulation discoverable in no other way, and in obtaining after their removal conductors with extremely good insulation.

With regard to the modification just described of the Neef hammer the following observation may here find a place. I had already made this modification in the year 1844 and given it the name of the voltaic inductor. It even then afforded me the opportunity of observing the therapeutic effect of the variable current induced in the second coil of such a voltaic inductor. My brother Frederick at that time was suffering a good deal of rheumatic toothache, which had affected his otherwise perfectly sound teeth and refused to yield to any prescribed remedy. The experiments with my new voltaic inductor led me to hit upon the idea of trying whether the variable currents produced by it could not remove the intolerable pain, or at least diminish it, if conducted through the roots of the teeth. This was actually the case with a particularly painful front tooth. The pain was at the first moment intense, but then suddenly quite ceased.

With the great force of will which at all times characterized my brother Frederick he at once proceeded to send alternating currents through all roots, and thereby obtained entire exemption from pain, which he had not experienced for weeks. Unfortunately however on the second day the pains returned. By repeated application of electricity their cessation was again effected, but the ensuing painless period became shorter, and at last the remedial agency altogether failed. This first attempt within my knowledge to employ galvanism for therapeutic purposes inspired me with a certain distrust of this particular application of the electric current. It appeared as if its action were only temporarily, not permanently, curative.

The ensuing autumn of 1848 was to me an exceedingly interesting and exciting one. The line to Frankfort-on-the-Main, where the German Parliament held its sittings and the vicar-general of the empire had his residence, was to be completed for political reasons as quickly as possible. This was however rendered difficult on the one hand by the disturbed political condition of affairs, on the other by altogether unexpected phenomena which manifested themselves in the underground conductors. My friend Halske, to whom had been consigned the fitting of the finished parts of the line with signalling apparatus, was the first to encounter these phenomena whilst I was engaged upon the line between Eisenach and Frankfort, which it had been resolved to carry above-ground, as the railway was still in course of construction—the land even having been only in part acquired.

Halske found first of all that with shorter lines our self-interrupting indicator telegraphs acted with much greater speed than corresponded to the resistance of the line. When communication between Berlin and Cöthen had been established a distance of about 95 English miles, the giving apparatus ran with double velocity whilst the receiving apparatus stopped altogether. This at the time inexplicable phenomenon occurred the earlier the better the lines were insulated, which induced Halske purposely to impair the insulation of the line by the addition of artificial watery by-passes.

The above-ground construction likewise encountered unexpected difficulties. Where the land for the future railroad had not yet been purchased, the owners would not permit the erection of the posts. This opposition was encountered especially in the non-Prussian parts, Hesse-Cassel and Hesse-Darmstadt, where the antagonism between the government of Prussia and the administration of the empire after the restoration of order in Berlin had become considerably acuter in consequence of the entrance of the army returning from Schleswig-Holstein. I only succeeded in executing my task by obtaining an open order from the vicar-general of the empire, Archduke John. Technical difficulties also made their appearance. The line was constructed of copper wire, as suitable iron wires were not then to be had in Germany, and moreover were still regarded with a certain mistrust. The unfortunate experiences which we had had the foregoing year in the case of the Berlin-Potsdam line, which despite the application of all sorts of insulating media proved so badly insulated in rainy weather that the proper service of the apparatus was constantly disturbed, had led me to make use of bell-shaped insulators of porcelain. These possessed the great advantage that the inner surface of the bell always remained dry even in rainy weather, whereby the insulation was secured under all circumstances. In fact I succeeded in this way in producing an almost perfect insulation. Unfortunately I did not then think it necessary to solder the copper wire, close coiling seeming to me sufficient. This afterwards turned out to be an error. In calm weather the apparatus acted very well, but with a strong wind the resistance of the conductor was so remarkably variable that the apparatus refused to work. Only subsequent soldering of all the joints put an end to this trouble.

The atmospheric electricity proved also very disturbing. In passing from level to high land currents of varying direction often traversed the communications and impeded the working of the apparatus. A late autumn storm caused widespread destruction, which led me to construct lightning-conductors for the protection of the lines and apparatus. In order to ascertain the most efficient form of lightning-conductors I set up between two paralled wire spikes, balls, and plates at equal intervals from one another, and observed the sparks, caused by the discharge of a large battery of Leyden jars, which passed between these three adjacent lightning-conductors. It appeared that very weak discharges took their course solely through the spikes, whilst stronger ones passed mainly between the balls, and very strong ones were carried off in a large number of sparks almost entirely through the plates. For actual lightning therefore roughened metallic plates placed nearly opposite one another proved particularly effective. The influence of the Northen Lights also made itself frequently perceptible, and at times in a very disturbing degree, especially in the underground line running mainly from east to west. Thus during the great aurora in the autumn of 1848 communication was interrupted for days between Berlin and Cöthen on account of violent rapidly changing currents. This was the first observation of the connection between earth currents, magnetic disturbance, and the aurora borealis.

When the underground line had been extended to Erfurt, Halske's watery by-passes were no longer sufficient. But meanwhile I had become convinced that the peculiar behavior of the underground wires could only be ascribed to the electrostatic charge already observed at the testings in the factory, the wires namely forming the inner, the damp soil the outer coating of a Leyden jar. Conclusive was the circumstance, that the quantity of electricity contained in a perfectly insulated conductor, measured by the deflection of a freely oscillating magnetic needle, was define itely related both to the electromotive force of the interposed galvanic battery and to the length of the wire; further that the electric tension of the charge in a closed conductor corresponded to the electric tension occurring at every point of the circuit according to the law of Ohm. Having perceived this, the impediments to signalling on long underground lines, could, if not be removed entirely, yet be rendered innocuous for practical purposes by suitable contrivances. These were the application of by-passes in the form of metallic resistances without self-induction, and automatic translation by which several closed pieces of line were united into a single large line.

---

* Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

My theory of the electrostatic charge of closed as well as of open circuits found however even in scientific circles at first but little acceptance, since it was opposed to the ideas prevailing at the time. Although it is not easy at the present day, when one can hardly conceive how a civilized man can live without railroads and telegraphs, to carry oneself back in imagination to that time, with the view of understanding the difficulties which we then encountered in things now regarded as a matter of course. Conceptions and helps, which are to-day familiar to every schoolboy, could at that time often only be obtained by effort and hard work.

I had the satisfaction of seeing this first long telegraph line—not merely of Germany but of Europe—already at work in the winter of 1849, so that the election of an Emperor, which took place in Frankfort, was by its help known the same hour in Berlin. This favorable result led to the determination of the Prussian Government to construct at once a line from Berlin to Cologne and the Prussian frontier at Verviers, and after that others to Hamburg and Breslau.

. . . .

The final decision of the question what turn I should give to my future life had now to be made. I decided for the last. To return to the military garrison service, after the exciting and successfully active life which I had behind me, I should have found altogether impossible. The civil service did not at all content me. There was wanting in it the feeling of comradeship which mitigates and renders endurable the oppressive differences of rank and power, there was wanting in it also the plain-spoken candor which reconciles one even with the bluntness which is traditional in the army. My brief experience of the civil service gave me sufficient grounds for the formation of this opinion. As long as my superiors understood nothing of telegraphy, they let me work entirely unchecked, and limited their intervention and instructions to questions of financial importance. That soon changed in the degree in which my immediate superior in office, Assessor, afterwards Counsellor Nottebohm, acquired knowledge of the subject during the progress of the work. People were assigned to me of whom I could make no use, technical arrangements ordered which I knew to be bad—in short, frictions and differences occurred, which marred the pleasure in my work.

To the acceptance of my request for dismissal was attached a remark of reprehension on a formal error in my petition. The political reaction had then become so strong that the German sentiments shown by me in the Danish war had become a reproach in governing circles.

In spite of the small final result of my military service I look back with a certain satisfaction to my military period. My most agreeable youthful recollections are connected with it, it paved my way through life, and gave me through the success I had achieved self-confidence for aiming at higher goals.

(To be continued.)

American Institute of Electrical Engineers.

The Eighty-second Meeting of the Institute will be held at headquarters, 12 West Thirty-first street, New York City, on Wednesday, December 20, at 8 o'clock P. M. A paper will be presented by Albert Stetson, Esq., on "The Practicability of Electric Conduit Railways." The paper will be illustrated by lantern slides. The December number of the Transactions will not be issued until after this meeting.

Ex-Surrogate David A. Pell, of Bergen County, N. J., has been appointed receiver of the Fort Lee, Leonia and Hackensack Electric Railway Company by Chancellor McGill. The railroad company laid about a mile of tracks, but lack of funds caused a halt. It is said the company owes about $9,000.

The Electrical Transmission of Power from Niagara Falls.—III.

BY PROF. GEO. FORBES.*

LINE CONSTRUCTION.

A great deal of attention has been given to the different methods by which current can be conveyed to the points of consumption, whether on our own property or at Buffalo, or even farther. Naturally the pole line was first dealt with, in which the poles might be constructed of either wood or iron. This is the cheapest type of construction, and has some advantages, but we must consider the climatic conditions in the neighborhood of Niagara Falls. We are subject there to severe thunderstorms, and troubles from lightning have already been serious in several parts of the United States in connection with electrical machinery. Snow and frost are very severe, and sleet forming upon the wires and insulators may cause a great amount of trouble. There are also at times very violent gales sweeping from over Lake Erie. All these difficulties can be counteracted to some extent, but it is nearly certain that with overhead construction occasions would arise when the continuity of operations would be interrupted, and this would be a very serious matter. The next system to be considered in order of cost would be underground cables, but I am strongly opposed to the adoption of these for any considerable length. It is true we are able to deal with their capacity so as to reduce its injurious effects, but surely the best plan of all is to abolish the capacity itself as far as possible. The most satisfactory method of proceeding is to build a subway of sufficient size to enable a person to walk along it and to carry bare copper conductors in it, but this is a matter of considerable expense. I am glad, however, to be able to inform you that the officers of the company resolved last summer that a subway such as I have described should be constructed from the power-house up to the Pittsburg Reduction Company's works, where aluminium is to be produced, a distance of 2,500 ft. In accordance with their instructions I prepared plans, which are now exhibited, and which give space enough to carry the conductors at 20,000 volts for all the power that will be developed by the present tunnel, parallel working being adopted. The subway is built of concrete having a minimum thickness of 10 in. The height inside is 5 ft. 6 in. Wooden beams are embedded in the concrete on both sides every 30 ft. When the concrete is set these beams are removed, and iron castings for supporting the brackets that hold the insulators are put in their place, and these are then grouted in. Iron brackets, as shown in the drawings, are bolted to these castings, and the oil insulators placed upon them. Copper wires are shown as being supported on these insulators, but we shall probably adopt copper strip. The bottom of the subway is always on an incline, and is of curved shape to drain off any water of condensation, but it is also proposed to force air through the subway so as to keep it dry. The 2,500 ft. now being completed is all drained at the power-house end by a boring into a water-bearing stratum. At the bottom of the subway the concrete is formed in two steps, the lower one of which supports sleepers for a very light tramway upon which a truck can run to carry supplies, and also to carry the inspector. At first this can be moved by hand lever, but arrangements are made for eventually driving it by electricity, the conductor being carried on the floor, between the stringers (placed on the ties or sleepers,) which form a platform running along the length of the subway. On the stringers outside the rails is placed a screen separating, mechanically and electrically, the part of the subway where the conductors are from the part where the inspectors walk. This screen is formed in 10 ft. lengths of wood supporting expanded metal, covered over with plaster up to a height of within one foot of the top, the upper part being left open in the form of a network, through which the inspector can look at the conductors and their supports. These screens are held by iron supports fixed by expanding bolts into the concrete, and can easily be removed. The top of the arch is 3 ft. below the surface of the ground, so that it will not be affected by frost. According to the last report, it appears that on October 21, 1,590 ft. of this subway had been completed; the total length being put down at present is 2,500 ft. Each of the iron castings has a wire attached to it which passes through the concrete, and is soldered to a copper wire running outside the subway along its whole length, and connected to a plate sunk in the water at any suitable points. At every 400 ft. cross streets will be made, and at these points there is a manhole. Also at these points, on each side of the subway, four drain pipes, 3 in. in diameter, are let in, closed at their outer ends. When the subway is to be tapped for use on the side streets, or for intermediate points, wires can be laid through these pipes. Between Niagara Falls and Buffalo there is very little rock, but the part where the subway has now passed through has been chiefly in rock. This involved blasting out a channel larger than was required. In this case the part of the trench outside of the subway has been built up of stone. In the construction of this subway American Portland cement has been used, and a very suitable sand from the neighborhood, which contains its own gravel. The whole of this work has been done by Mr. Humbert, and up to the date of my last inspection every part was thoroughly and satisfactorily done. This work is of great importance as conveying to the minds of those who intend to use our power some idea of the desire to ensure continuous working.

With regard to the electric pressure that is to be used for distant transmission, this will undoubtedly advance with experience. Some manufacturers in Europe who tendered for the work proposed to adopt 25,000 volts; but we have considered that at present 20,000 volts is not likely to be exceeded by us, and we may work at a low pressure at the commencement. When it is remembered that the Deptford machines have one terminal connected with the earth, and are working satisfactorily at 10,000 volts, and when it is noticed that, in consequence, our work would be under exactly the same conditions as regards insulation when working at 20,000 volts, it is easy to see that we are not risking anything experimental in our first work.

With regard to the size of conductors, I worked out the economical size at different current densities for the whole distance. In doing this I took the following data:—I took the cost of copper at 12½ cents per lb., and the annual charge on this cost at 5 per cent. I then computed the power loss in the line, and the amount of power which was left available for delivery. I took the value of this power at the distant end of the line as being $15 per horse-power. This is something more than what it costs us to produce it, but when the power available from our tunnel is nearly all consumed this quantity will have to be increased. It must also be remembered that I have not allowed for the increased size of the conductors required by the retardation of phase, which is an unknown quantity. Still, it will be seen that from these considerations we may be able to work economically at a slightly higher current density than is obtained from this investigation. From this work it appears that the most economical density to work at is 350 amperes per square inch. If this density is used, the fall in volts between Niagara Falls and the northern boundary of Buffalo is only 3½ per cent. — a matter which makes regulations extremely easy.

---

* From a paper read before the Institution of Electrical Engineers, England.

With regard to the efficiency of the system, it is remarkable how high the efficiency of the dynamos comes out when we are dealing with the large units of 5,000 H. P. There can be little doubt that the efficiency, electrical and mechanical, of our dynamos may reach at least 98 per cent. Taking off 3½ per cent. for losses on the line, we would have 94½ per cent. delivered electrically at Buffalo if no transformers were required to raise the electric pressure to the full 20,000 volts. In cases at Buffalo, where the power consumed is very large, the motor can be constructed on the same principles as the dynamo; and if in this case it be ever possible to work at the full pressure without a transformer, it is obvious that the total efficiency of the system—that is, the power delivered by the motor to the shaft of the machinery, divided by the power delivered by the shaft of the turbines to the dynamo—will be certainly over 90 per cent. As a matter of fact if we were to use a higher density of current, and were to use step-up transformers at Niagara Falls and step-down transformers at the northern boundary of Buffalo, and other step-down transformers in the town of Buffalo itself, and were to use motors of small power and consequently less efficiency, in this case the total efficiency of the plant might be reduced to 80 per cent., or even lower.

I have given these figures, not as indicating precisely the lines on which we have determined to work at Buffalo, but because the present Paper is intended to embrace the subject of the general distribution of power, and I thought it desirable to lay before you certain facts in this connection in a definite form.

DESCRIPTION OF MACHINERY TO BE USED.

Under this heading I shall deal chiefly with the type of dynamo which has been finally decided upon. It will suffice to say of the turbines that they are each of 5,000 H. P., that they revolve at 250 revolutions per minute, and were designed by Messrs. Faesch and Piccard, of Geneva. All the principal parts of this machinery were constructed by the I. P. Morris Company, of Philadelphia, but the governors of the turbines are of Swiss manufacture. and part of the steel fittings were constructed in France.

With regard to the dynamo, the Cataract Construction Company at first invited many different manufacturers in Europe and America to submit plans. The number of these that were submitted altogether amounts to 24, some of the manufacturers having taken a great deal of trouble to submit a series of designs, in order to be able to meet different requirements. Many of these designs were extremely good; but it was determined, after estimating the increased cost of using the European designs, owing to the high tariff in America, and owing to transport, to have the machines manufactured in America. Among the designs from American manufacturers there were none which fulfilled all the requirements of the case, and eventually the Cataract Construction Company decided to get out their own designs, and to submit them to the American manufacturers for tender. I had been for some time previously engaged in working out a design which I am confident none of the manufacturers who had sent in designs could say was in any way borrowed from their ideas. We had received suggestions of an external amature with internal revolving fields, and also of external fixed fields and internal revolving armature. We naturally had a preference for a dynamo with a fixed armature, because the coils can be more securely wound, and are not subject to the mechanical stresses induced by centrifugal force. But all the designs with revolving fields which had been submitted to us contained a weak feature: the field coils were held in by pole faces secured by bolts or keys to the poles, and this seemed an element of weakness when we considered the enormous centrifugal forces to which the machinery would be subjected. At the same time the turbine makers had insisted upon having a certain momentum, or fly-wheel effect, which was not given by the revolving parts of any of the dynamos submitted to us, and it was found that if anyone of these had been accepted it would have been necessary to add to the design a fly-wheel of large dimensions. Centrifugal force was one of the most important matters to be considered, because at 250 revolutions per minute this force assumes considerable magnitude in the large masses with which we had to deal. Moreover, in all the designs which had been submitted, the magnetic pull between the poles and the iron of the armature assisted the centrifugal force. The principal feature of the design upon which I was working consisted in having the armature fixed, and inside the machines, with the fields revolving outside; the fields being formed of a ring of iron with the poles projecting radially inwards. One advantage is that we are able to get the full fly-wheel effect that was required by the turbine makers. This requirement was that in the revolving part the sum of the weight in pounds of each part, multiplied by the square of its velocity in feet per second should equal 1,100,000,000. The design also gives an extremely good mechanical construction for the revolving parts. The iron ring which forms the yoke of the fields serves as a support to hold in the pole-pieces and the exciting coils, and no part is held in against centrifugal force by bolts or keys. Moreover, the magnetic pull between the fields and the armature acts in opposition to, and does not assist, the centrifugal force. The armature is fixed, and a large space is available inside of it for the workmen to attend to the bearings, and to reach any part of the armature. It is obviously possible to insulate the armature coils for any electric pressure. With a large machine of this kind, the space occupied by insulation has not the same importance in reducing the output of the machine as is the case with machines constructed in the past. In fact, the armature coils can be wound with the same insulating properties as a transformer, and hence the necessity for using a step-up transformer can be avoided.

Starting with this general principle, I first got out designs of a machine at 33 periods per second, in order that I might compare the general appearance of such a machine with those of other types. The next point was to design a machine of as low frequency as was possible under the limiting conditions as to weight. The revolving parts of the turbine and dynamo, and the shaft connecting them, are supported by a hydraulic piston, and it was the desire of the Cataract Construction Company not to use a thrust bearing of any kind to support the weight, although there is a thrust bearing at the top of the shaft, which simply acts to retain the apparatus in a fixed position in a vertical direction. Owing to this decision. it was necessary to limit the weight of the revolving parts of the dynamo to 80,000 lbs. In getting out the design for this machine it was desirable to select such a form of winding as past experience led me to believe would be most efficient for parallel working, and I judge from past experience that this is best attained by having the number of coils per pole very small. The 33-period machine which is shown in the drawings has only been sketched out with a view of getting at the general dimensions of the machine. It is not suitable for our special purpose, because it is essential that, without taking the dynamo altogether to pieces, we should be able to lift up through the centre of the dynamo any parts of the turbine shaft which may require repair.

It will be seen that from the necessities of the case at Niagara Falls the dynamo which was required differed in some respects from what would be necessary in many other cases, but it is equally obvious that in any case of so large a transmission of power the conditions must be thoroughly considered beforehand, and the dynamo specially designed for the purpose. At the meeting of the Board of Directors of the company, in May, 1893, I was instructed. with Dr. Sellers, to get out plans for an alternator of the type which I have described.

I am not able to lay before you now plans of the machine as it has been finally adjusted by conference between ourselves and the manufacturers. In the plan which we prepared, the frequency was 16⅔ periods per second, there being eight poles. The armature coils were so wound that they might be connected to give either 2,500, 5,000, 10,000, or 20,000 volts. and the coils were limited in number so as to give the best assurance of good parallel working. For various reasons we decided eventually to raise the frequency to 25, and to lower the volts to 2,000, without the means of connecting the coils to give a higher pressure; and instead of winding the armature on the conductors in a limited number of coils, to adopt the methods more commonly used in some of the large types of generators, But since in any future work which is done the dynamo will be required to be modified for the special purpose, a description of the machine —of which I am able to show you the drawings* —is sufficiently representative of the type of machine for our purpose.

(To be Continued.

Modern Uses of Electricity—V.

DISTRIBUTION OF ELECTRICITY FOR COMMERCIAL PURPOSES.

This was the topic on which Professor Cross spoke on Monday evening, November 20, at the Massachusetts Institute of Technology, and in entering upon its consideration he said that the temperature of the electric arc was so enormously high that it affords a means of fusing refractory substances, which was a very great advantage not only in the laboratory but in actual practice. With a simple apparatus, almost the same in principle in construction as an arc lamp, a piece of zinc was instantly fused when the current was turned on. In volatilizing other substances an electric furnace could be used, the same being invented by Siemens some twenty years ago. It consisted of a plumbago crucible into which passes a carbon rod, this being the pole while the crucible formed the negative. The substance to be treated was placed in the crucible, and the carbon being brought into contact with it an arc was formed, the crucible became heated and the substance fused. This principle had been utilized by the Cowles Brothers for smelting aluminium from an ore containing from 75 to 80 per cent. of pure aluminium. In this process, copper, carbon and ore were mixed together and aluminium bronze was the product. Common clay was being treated for the same purpose, but containing only something like 12 per cent. of aluminium it did not pay to extract it. There are the Cowles and the Hall processes of electrically reducing ores in operation.

Passing on to the subject of electric heating, it was stated that for many purposes, such as cooking in a great variety of ways, heating soldering irons and similar purposes, electricity was very available. It had not yet been thus utilized on an extensive scale, but this new department was deserving of consideration. It was not yet possible to utilize the electric current for heating very large spaces, such as buildings, thus superseding the use of furnaces, but this process was practicable for raising the temperature of a room beyond the point to which it had been raised, say by a furnace or other system of heating.

---

* Diagrams were shown at the meeting, but none of them have been received by us for publication.—Ed. E.

Illustrative of what was now being done in the department of electric heating, the lecturer then showed a variety of cooking and other utensils manufactured and loaned to him by the New England Electric Heating Company, describing their construction and uses and informing his audience that at the present time cooking was being regularly done by electricity at the American House, one of the principal hotels in Boston.

Passing on to electric lighting by incandescence, he remarked that the history of this department was particularly interesting, because it brought them some idea of the many attempts that had been made ere success was attained.

In 1845 a Mr. King, of Cincinnati, used carbon in the manufacture of incandescent lamps, but it was never recorded what progress he made, though it was reported that he operated successfully ten or twelve lights in Manchester, England, at a private exhibition when Michael Faraday was present.

Other early experiments were made by Mr. Moses G. Farmer, in 1869, in lighting a house near Salem, Mass. This, however, is said to have been done by using a platinum ribbon.

The incandescent lamp has been evolved out of the persistent labors of many different workers, of whom the best known was Mr. Thomas A. Edison. The modern type of incandescent lamp consisted of a small thin thread of carbon through which an electric current passes after the carbon has been placed in a vacuum to prevent combustion.

Lane Fox in England and Edison in America were among the earliest successful workers in this field. The latter began by making a lamp having a filament of platinum of very high resistance. The great objection to a lamp made of platinum was that the limit between the point of incandescence and melting was so narrow that the lamp was liable to break down at any time.

It was the platinum lamp in 1878 that so suddenly brought down the price of gas stocks on its introduction and not the carbon lamp as now used. Edison was able to improve the platinum lamp when he found that the breaking down was generally due to the cracking of the wire caused by the ebullition of gases that had been occluded and which were liberated when the current was increased. Abandoning one particular line of work he started out on another and finally succeeded in bringing out the lamp which bears his name to-day.

One of the first things of importance in the making of incandescent lamp filaments was to select a substance that could be easily carbonized. Edison first used paper, but abandoned it for bamboo, certain fibres in which just met his requirements. His company has hitherto proceeded on the assumption that it was best to carbonize the filaments before using them. Silk thread has also been used extensively. Flashing filaments by submerging them in petroleum and passing a current through them is very general; it makes them strong and even in tension. Of course it was necessary to attach the filament to the leading-in wires. These have usually been made of platinum, because it can easily be sealed in the glass bulb, the coefficient of heat of glass and platinum being very nearly the same.

The vacuum in an Edison lamp is equal to 1-80,000th of an atmosphere; with the use of a Sprague pump a vacuum of 1-1,000,000th of an atmosphere is possible. The necessity for a vacuum is because if there was any oxygen present in a lamp, of ever so small a quantity, the carbon filament would be instantly burnt up. This is not the only reason for placing the filament in a vacuous chamber. There was the additional reason that what was known as "air-wash" was very destructive of the filament, this being the action of some molecules of air on the filament. No one has yet been able to ascertain what is the least number of molecules of air that would render a lamp useless.

Within a recent period what are called "stopper" lamps have been placed on the market. All lamps that have been held to infringe the Edison lamps contain the carbon filament placed within a chamber having a vacuum in it to prevent "air-washing," with platinum leading-in-wires.

The lecturer then minutely described at great length the making of various types of incandescent lamps, showing a number of the "New Beacon" lamps which had been placed at his disposal for that purpose.

Showing a Westinghouse lamp of 50 volts, Prof. Cross attached it to a 110 volt circuit to illustrate how it could be so used by means of a resistance box. By increasing the pressure of a current to secure greater brilliancy, the life of a lamp was shortened. It was an open question what should be termed the life of a lamp—the period the filament lasts, or the time that elapses before a lamp blackens so that it cannot be used any longer.

In using lamps, the higher the pressure of the current the more expensive, and vice versa. Lamps generally give out by the breaking down of the filament, which is weak. After speaking of the hundreds of measurements that have been made to ascertain the C. P. of lamps, and the efforts of inventors to get a good light on a horizontal plane, the lecturer called his audience's attention to the spectra of the arc light, incandescent light and gas light. He pointed out that there were more red rays in the arc light than in the incandescent, and less in the gas light, and stated that the higher the incandescence the better the light. What inventors to-day were after was the discovery of a filament that could be heated with a small current and yet give a better light.

Next, discussing the loss of light and heat by radiation in all kinds of artificial light, the lecturer showed that there was an immense waste going on; what the amount of loss was, and how to correct or obviate it, was a subject engaging the closest attention of the most prominent scientists, and with the aid of delicate instruments already in use, there was a not very remote possibility of this problem being solved.

ELECTRICAL TRANSMISSION OF ENERGY.

This was the topic on which Professor Cross spoke at Huntington Hall, Boston, a few evenings ago, the address being one in the series of lectures he was giving on "Modern Uses of Electricity." In entering upon the lecture, the speaker said that a motor, when running, sets up a reverse electromotive force which increases from zero when the motor is not running to its maximum when the motor is doing the heaviest work possible for it to do. This fact was illustrated by passing an electric current through a small motor and lamp. Under this arrangement if the motor was prevented from turning or running, then the lamp would glow quite brightly. If, however, the motor was allowed to start up and increase its velocity, then the lamp would glow gradually dimmer and dimmer. It was shown that when the speed of the motor was such that the inverse electromotive force was half of the current passing, the mechanical work done was greatest.

The efficiency of a motor was the ratio between the electromotive force of the current furnished to the motor and the inverse electromotive force of the motor. On this depended the commercial success of the electric transmission of energy.

Passing on to the subject of lighting, Prof. Cross said that electric lamps are run in either "series" or in "parallel." Arc lamps are usually run in series, thus requiring a constant current in the circuit. This constant current was secured by means of a current regulator. Incandescent lamps were usually installed in parallel or multiple arc, which requires a constant difference of potential between the terminals of the dynamos. Shunt machines, as they were called, were usually used for this purpose, but do not regulate themselves very well under great variations of load. Compound wound dynamos were now being used very generally for incandescent lighting. These machines had a combination of shunt and series winding, and could regulate themselves under great variations of load. The electrical mains, like water mains, must be made so large that the diminution in voltage along their length is very small. Various systems of distribution were used in case of central stations. The series system used very small current, with but small loss. It required, however, a high electromotive force, and was thus dangerous to handle. The parallel system uses a low electromotive force, and was therefore harmless but required large conductors, which made it costly. The series parallel system combined the first two, but was used only in running incandescent lamps on arc circuits.

The converter system was one in which the current generated at the station was used to produce local currents at the places where they were to be used. There were several forms of this system, but the transformer system was the most important and the one most generally used. Its greatest advantage was where the current had to be carried long distances. The objections to it were inferior regulation and danger from the current, especially in case of inferior insulation in the transformer. Two important additions had been made to the parallel system during the last few years. These were the system of "feeders," and the "three-wire" system, both of which greatly reduced the cost of wiring.

The lecture was interspersed with views of various types of generators, isolated and central station plants at home and abroad, together with maps of the underground system of electrical distribution as it is in existence and operation in Boston at the present time.

He Sawed the Conduit.

How Supt. O'Neill, of Rochester, Mended a Water Main.

A few nights ago the continued ringing of gongs in the fire and police patrol service at Rochester gave warning that something was wrong. City Electrician Barnes, with the superintendent of construction of the Telephone Company, soon discovered that a large portion of the city was absolutely cut off from all connection either by telephone, fire alarm or police patrol service. An investigation disclosed the fact that the Superintendent of Public Works, Mr. O'Neill, finding that the electric conduit retarded his progress somewhat in the repair of a water main, had deliberately sawed the conduit in two places and removed a piece about a foot in length. The conduit contained seven cables.

Mr. O'Neill is still unable to perceive that there was anything unusual in this. A Rochester reporter says: "The superintendent appeared to be completely exhausted from the effects of his night's work, and it was only by repeating each question several times that an answer could be obtained."

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

United States,	$2.50
In Clubs of Five or More,	$2.00
Foreign Countries,	$4.50
Single Copies,	$ .10

ADVERTISING RATES:

As Electricity reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

Entered at the N. Y. Post Office as Mail Matter of the Second-Class.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

SEPARATION IS THE PLAN.

From all the information at hand as we go to press, it is believed the present plan of reorganization for the General Electric Company is to effect a separation of the Edison and Thomson-Houston interests.

The scheme is believed to be well under way, the details being settled as far as the Directors are concerned.

Legal obstacles may arise, but there is little doubt that it is intended to sell the Thomson-Houston stock, now held as a treasury asset by the General Electric Company, to a syndicate of Boston capitalists, headed by Mr. Coffin. The Thomson-Houston Company will, it is believed, go into business at the old stand, of necessity confining its attention chiefly to railway work.

The General Electric Company would be in reality the Edison Company, and the name of Edison would doubtless be speedily taken on again.

We leave speculation on the foregoing to our readers, and the settlement of bondholders' and mercantile creditors' claims to the courts, a receivership being no doubt necessary as the preliminary step.

It is common talk in Boston that the labels "G. E. Co." on all working machinery in the Lynn works have been planed off, and the old-time labels, "T. H. E. Co.," substituted therefor.

It has been generally supposed that a separation could not be carried out. That is a question, perhaps, which the courts will have to decide, but there does not seem to be any inherent impossibility in its solution. The Thomson-Houston Electric Company is still in existence legally; its stock is owned by the General Electric Company, and the latter company is authorized by charter to buy and sell stocks of other companies. Certainly the Thomson-Houston people cannot *withdraw*, but if the General Electric Company wishes to sell its Thomson-Houston stock to a syndicate, we believe it can do so.

Indeed a careful review of the situation from the day Mr. Coffin was placed in the saddle lends some color to the view that this is a plan which he always had in mind. First, there was the extermination of the name of Edison from all the company's literature; then the sale of nearly all the stocks of Edison licensee companies—valuable assets and becoming more valuable every year; later comes the reported gutting of the Schenectady works; and throughout the whole the studied and successful effort to break up and scatter the selling machinery of the old Edison Company.

The Edison people cannot fail to see now, what they evidently did not see two years ago, that they gave up the ghost just at the time when the long-fought for success was within their reach. A slight additional investment of capital and another year of good management would have placed them in an impregnable position. Further than this, the Thomson-Houston Company would have been soon declared bankrupt. It is just possible that the Edison interest believes it could start now where it left off two years ago.

$50,000 Reward.

The offer of the Metropolitan Traction Company of the above sum to the inventor of a practical method of street car propulsion is printed in another column, and as the implied preference is for an electric system which shall avoid the use of overhead wires but be as economical to operate as the trolley system, the electric conduit is probably the method which most nearly complies with the requirements. There are no doubt a number of inventors who will lay claim to this prize at once on the strength of the various conduit systems which have been designed and experimented with, and the feeling among electrical engineers is pretty general that there is no inherent difficulty in the way of a conduit trolley system except the high first cost of building such a line. As this is practically the same as an overhead trolley system except in the location of the trolley, the operating expenses of the conduit road would be likely to prove about the same as the trolley system in general use, and it would further have the advantage of being less liable to depreciation and repairs if substantially built at first. The trouble arising from the use of a grounded return can also be avoided, as it is about as easy to run a double as a single circuit in the conduit.

The only place where this has been tried on an extensive and practical scale is at Budapest, where about twenty-five miles of conduit road has been in operation for some time and from which very satisfactory results have been obtained. Aside from the cost of this system, the objections which have been raised against it for use in American cities are entirely without foundation, and relate merely to minor details which could readily be modified to suit the conditions in our streets.

The width of the slot is the trouble most frequently heard of but is in reality of no importance. The slot used in the Budapest road would certainly be impossible to use in New York, but it is a perfectly simple matter to design a trolley which will run in a slot even narrower than those in use on either of our present cable roads.

The drainage of the conduit is another point which is held up as a chief objection to the conduit, and is of course an essential quality in such a system, as the insulation of the trolley wires depends upon this. The wires to be kept entirely beyond the reach of water must be placed in a conduit sufficiently large to act as a drain for all the water that can ever run into it, and connections to the sewers must be frequent enough to prevent the water from rising above a definite height in the conduit. This, however, offers no engineering difficulty, and is merely a question of the first expense of the construction.

The climatic conditions here have also been used as an argument against the conduit system, but when we consider that the Budapest road is operating in a climate subject to the same variations and extremes as our own, this objection is without weight, and it seems impossible to avoid the conclusion that a conduit system of the class mentioned, viz., one employing bare conductors supported near the top of the conduit, is not only feasible, but has been demonstrated a practical success.

The cost of installing such a system would vary from $50,000 to $100,000 a mile according to the local conditions and topography of the road. The drainage of the conduit is the essential requirement, and in most of the experiments tried in this field this requirement has not been fully met. Where the traffic is sufficient, however, to warrant the expense of a conduit large enough to supply the necessary drainage, electrical engineers are in a position to-day to equip and guarantee an underground trolley system.

Another plan which offers a considerable advantage over the bare trolley wire, but which has not yet passed the test of a practical commercial application, is the conduit with insulated trolley wires, from which no current can pass except at the point directly beneath the car. A system of this description has been installed on an experimental scale at Coney Island and was described in detail in ELECTRICITY of July 5, 1893.

The special merit of this plan is the fact that the pressure of water in the conduit will not give rise to any leakage of current between the trolley wires except at the point where a car is standing, and experiments with a conduit filled with mud and water showed the leakage with one car to be hardly noticeable on the station indicators.

Whatever system may be chosen, there can scarcely be any doubt that numerous plans will be forthcoming when it is generally understood that a company such as that offering the reward can be secured as customers.

……o……

No Deal in Cleveland. There has been talk for the past three months of a new combination, embracing the Brush and Fort Wayne Companies. We do not know anything of the Fort Wayne end of this plan, and doubt if it ever was received seriously there. But it is a fact that Mr. Coffin some time ago, when threatened with immediate retirement from his present position, made the effort of his life to induce Cleveland capitalists to purchase from the General Electric Company the stock of the Brush Company, thus giving him, as he at that time supposed, one more chance to juggle with stocks and deals.

The effort proved a complete failure.

The scheme was doubtless conceived months ago, when several prominent capitalists in Cleveland were elected officers at handsome salaries in the Cleveland General Electric Company, a company whose stock is all held by the parent company. After a few months the services of these men, headed by Mr. M. H. Herrick, were all enlisted by Mr. Coffin in the endeavor to raise a little matter of four millions. The local pride for which Cleveland men are noted was worked upon to the full extent, but the banks did not take kindly to the scheme, and there are those who say that Mr. Coffin's friends played him double; while working industriously for him at interviews where he was present, they called again after he had left town, to explain their correct position. And in addition, the Brush-Thomson-Houston deal has not passed so far into history but that it is vividly remembered by several Cleveland capitalists. Mr. Coffin is a plausible man, but it was really asking too much of Clevelandites to allow themselves to be done up twice within five years. Another circumstance which doubtless operated against Mr. Coffin's brilliant efforts was the condition of the carbon company. Mr. Coffin's connection with this deal would make a long story, but it is sufficient to say that some of the officers of the company are indebted to him for their present prominence. Like many others, they have learned that his favors were purchased at a high price, and it is said in Cleveland that the money which was in the treasury of the company was borrowed by Mr. Coffin, has not been repaid, and that consequently work on the new factory has been discontinued for some time.

If the Brush enterprise is again to stand alone, which is next to impossible, it will not be backed by Cleveland money.

……o……

A Question Easily Answered. A representative of this paper was recently told by an advertiser that he had tried all the papers except ELECTRICITY; that they had all treated him unfairly except the *Electrical World*, and that he had no reason to suppose we would be unlike the others. Pressed for an explanation, he replied that all the other papers had worried him in regard to payments; that he now owed the *Electrical World* for three years' advertising, and that they had not troubled him for the account.

This case is of some interest at this time, as it goes a long way towards answering the question our contemporary has asked of every advertiser in the trade as to why its advertising patronage had not decreased in the same proportion as that of its competitors.

We have reason to believe there are a score of practically similar advertisements in our contemporary—advertisements of dead-head concerns, who sell cheap goods at cut-throat prices, and who are enabled to continue their course as trade-disturbers because their advertisements are virtually carried free. Reputable concerns who pay their bills have an interest in this matter deeper than that of the journals whose business is perhaps temporarily injured by this ill-judged policy of a dishonest contemporary.

The law of business is the survival of the fittest, and legitimate concerns should not be subjected to the competition of irresponsible ones by the aid of the paper which the good money of the former has built up.

……o……

THE collapse of the Northwest General Electric Company leaves a practically clear field for the rejuvenated National Electric Company at Eau Claire, which starts off under extremely favorable conditions. It has a plant which originally cost $200,000, and which it has acquired for $12,000. The paid up capital of the new company is $50,000, thus leaving $38,000 on which to begin business, with no debts. Messrs. A. L. and F. P. Ide, of the Ide Engine Company, are respectively president and secretary of the National Electric Company. Their names will inspire confidence throughout the trade.

ATTRACTED, doubtless, by the fabulous amount of money made by the electrical papers this year, two new enterprises are about to be launched. One of these is a monthly magazine, which, if properly conducted and backed by $100,000 of cash capital, ought to make a go of it. For the other the prospects are not so bright. It has long since been decided that financial reports have no place in a periodical which depends for its support upon the advertising patronage of the concerns reported upon. Many such publications have been started; none has proved successful. Every one has, sooner or later, degenerated into a blackmailing sheet, or the next thing to it, withholding unfavorable reports for an advertising consideration. The promoters of the new enterprise at present have the respect of the trade, but we warn them thus early that their plan is impracticable. Human nature will have to change before any such scheme can be successful.

……o……

IF THE details of Mr. C. A. Coffin's many schemes to get the money of banks invested in his various enterprises are ever told in court, many things will be made plain which are now enveloped in mystery. The distinction between a confidence man and a financier would be clearly shown. Just now a few side lights are being shed on this subject in the trial of Mr. H. G. Allis, the Little Rock banker, who has fully recovered from the hypnotic spell after his bank and all his other enterprises are ruined.

……o……

ABOUT a year ago, when General Electric shares were at 115, we called the attention of the officers of that company to the fabled hen of old who tried to lay a goose egg; it will be remembered that this hen ruined herself and broke the egg. Compelled to sell lamps at 26 cents, and with every other branch of its business in even worse condition, we submit that the egg is broken and the hen is permanently disabled.

……o……

MR. C. A. COFFIN'S star has set. He has failed where a less able but more honorable man might have succeeded.

……o……

THE importance of the victory won by the Columbia Lamp Company at St. Louis is becoming more apparent every day. The fight the company made was thought to be bad judgment by nearly every one in the trade, the general opinion being that new lamps could alone be looked to to break the monopoly of the General Company. Mr. Rhotehamel's judgment, however, proved correct, and he deserves the success which his company is enjoying.

……o……

MR. W. J. HAMMER, whose connection with the General Electric Company, so we were told, ended some time ago, was almost the first purchaser in this city of the new Packard lamps. He bought a full assortment. These lamps, strange to say, were found later in the testing room of the General Electric Company. Mr. Hammer is a very clever gentleman, and is now publishing *The Buyer's Directory*, for which, we believe, advertisements are solicited from independent concerns, including the lamp men in whose business and product Mr. Hammer has shown such brotherly interest.

……

THE advertisements in any first-class publication are worth reading. In them may always be found poetry, philosophy, even religion, and truths tersely told. No editor in the sanctum of the *Sun* could say more in few words than is contained in the following from a late clothing advertisement: "If we were you, we'd rather have an ulster than a life insurance policy. The epitaph on many a grave might appropriately read: 'He ought to have worn an ulster.'"

What Coffin is This?

(From the Evening Post.)

Acting upon the report of Bank Examiner Clement Dowd, State Treasurer Tate instructed the sheriffs of Cumberland and Robeson Counties to close the branch banks of the Banking Association of the Carolinas at Fayetteville and Lumberton, N. C. The president of the bank, John P. Coffin, is notified to appear before Superior Court Judge Whitaker at the next term of Northampton Court to show cause why a receiver should not be appointed and the affairs of the banks wound up.

These "banks," it appears, were very shaky concerns. The "stock" was $22,400. Two thousand and four hundred dollars of this amount was subscribed by citizens of Lumberton, while the other $20,000 was supposed to have been subscribed by Coffin and his wife, who live at Florence, S. C. The bank was chartered one year ago. When the bank examiner investigated the "branch banks" a few days ago, he found in the one at Fayetteville $161, and in the one at Lumberton $83. It was also discovered that President Coffin had borrowed all the money the banks were supposed to possess, with the exception of the above-mentioned $244. He asks for time to repay the money.

Although somewhat familiar with Coffin genealogy we have not learned whether or not John P. is a brother or cousin of Charles A.

Thomson-Houston Financiering.

How F. L. Ames Was Robbed of $300,000.

(From the United States Investor.)

One of the most melancholy consequences so far noted of the misfortune that has overtaken the General Electric Company is the announcement that the Northwest Thomson-Houston Company is in process of liquidation. The money invested in this enterprise is large, and it is to be feared that the loss to the stockholders will be well-nigh total. The company was one of the *proteges* of the old Thomson-Houston Company, which owned a control of the common stock. The Thomson-Houston people recommended the Northwest Company to their friends as a very promising field for investment. The preferred stock was issued to Thomson-Houston stockholders at par, and sales were later made at 115. Of the $750,000 preferred stock about $300,000 was owned by the late Frederick L. Ames, who paid a high price for his holdings, and who was a strong believer in the enterprise.

The Northwest Thomson-Houston Company was always represented by the Thomson-Houston people as being highly prosperous. This was particularly the case about two years ago, when efforts were being made to market a block of the preferred stock.

The experience of the Northwest Company can hardly help adding to the uncertainty now felt by the security holders of the General Electric Company regarding their property. The complete collapse of the Northwest Company reveals the exceedingly insecure basis on which the electrical business has been conducted. The company was regarded by most persons as strong, and those who knew most about it were the most urgent that their friends should buy its securities. How great then must be the distrust which the downfall of the Northwest Company will engender in all minds regarding other electrical enterprises, and especially regarding the General Electric Company.

Continued Prosperity.

The Brooklyn Edison Company has declared the regular quarterly dividend of 1½ per cent.

More Lawsuits.

The Edison Lamp Patent in Philadelphia.

Suits have been begun in Philadelphia against the Manufacturers' Club, the Philadelphia Trust, Safe Deposit and Insurance Company, owners of the Colonnade Hotel, and George J. Crump and Henry J. Crump, lessees, and the Spreckels Sugar Refining Company, to restrain the defendants from continuing the purchase and use of incandescent lamps alleged to infringe the Edison patents.

Also a Feeder Patent Suit.

The General Electric Company has secured a temporary injunction against the E. G. Bernard Company, contractors, alleging intended infringement of the Edison feeder patent in the equipment of the plant at the Watervliet Arsenal at Troy, the contract for which was secured by the Bernard Company in competition with the General Electric Company. The hearing is set down for January 2.

Legal Notes.

City Attorney Carothers, of Newport, Ky., has filed the answer and cross petition of the city in the suit brought by the Electric Illuminating, Heating and Power Company for the recovery from the city of the sum of $26,486.86, due on its electric lighting contract. The answer goes fully into the history of the case and makes the square and direct issue of fraud and collusion in the granting of the franchise between the officers and agents of the Electric Company and the Mayor and council. The city attorney prays the court for judgment decreeing a cancellation of the contract and that it be set aside and held for naught.

In order to have the highest judicial test of the right of rural electric railways to be on earth within the confines of the State of Pennsylvania, equity proceedings have been begun in Montgomery County, in that State, the result of which will establish a precedent for like contentions in other parts of the State. Two questions are at issue. One is, Are country highways or roads "streets" within the meaning of the law under which electric passenger railway franchises are granted? Question two is, Have township supervisors the authority to grant railway companies the use of country roads? In the equity suit instituted by the Pennsylvania Railroad Company against the Montgomery County Passenger Railway Company, Judge Weand has refused the injunction asked by the plaintiff to restrain the defendant corporation from constructing its roadbed on the highways or roads of the country districts. He holds that the words roads, highways and streets are identical and are interchangeably used in the law, and, furthermore, that supervisors are the proper officials to grant the use of roads in townships. To this decision the plaintiff excepted, and Charles Hunsicker was appointed master to take testimony for the purpose of an early hearing and adjudication by the Supreme Court.

In the case of the Westchester Telephone Company against the Long Island Electrical Construction and Supply Company, an action brought to restrain the Long Island Company from operating a system of electric-light and power wires on the same side of the street and near the telephone wires on Main street and Throgg's Neck Road in the town of Westchester, on the ground that the wires of the electric company would be charged with heavy current necessary for arc lighting, and would after a short exposure to the weather become dangerous, etc., Judge Bartlett announced that he would continue the injunction already granted in as far as it prevented the construction of the arc line within eighteen inches of any telephone wire and the placing of the wires above those of the telephone company. The rules of the State Board of Underwriters require electric light wires to be placed above the telephone wires, and the decision is in direct opposition to this rule.

CORRESPONDENCE.

"Electricity" Is Appreciated.

To the Editor of ELECTRICITY.

DEAR SIR: I am unluckily a stockholder in the General Electric Company, and for some time past have been a careful reader of ELECTRICITY. From what I have learned through your columns of the fraudulent character of the Electric Trust and the utter unscrupulousness of its officers, I am no longer surprised that my holdings have decreased in value until they are to-day scarcely worth the paper which represents them.

Business relations which I have had from time to time with its New York office convince me however that, in addition to being handicapped by a dishonest management, the General Electric Company's prosperity is being retarded by incompetents in its executive offices and in some of its departments. The pompous puppet who rattles round under the title of "Assistant Manager," and whose prototype is to be met with in many of the other offices, has been an expensive luxury to the stockholders; and the consequential anthropoids and cranks who are walking about on their hind legs in the mismanaged railway department have undoubtedly contributed not a little to the ruin of a magnificent business.

Until the General Electric Company throws off its incubus of jejune managers and dudes, it cannot expect to recover its lost prestige with business men. Very truly yours,

JUNIUS.

Plainfield, N. J., Dec. 7, 1893.

(From a Private Letter.)

I wish to assure you of the kind feeling I have towards ELECTRICITY, and especially toward yourself personally, and my appreciation of the work you have done. Few realized a year ago the danger that the electrical interests were in, and few appreciate now their narrow escape. I believe you have done more than any other single agency in averting what might have been a serious calamity to the whole electrical interests. In future I may be able to show my appreciation in a more substantial form than I can at the present time.

Another Lamp Decision.

Repairing Lamps Held to Be an Infringement.

An injunction has been granted by Judge Colt, of the United States Circuit Court, at Boston, against the Davis Electrical Works of Springfield, enjoining them from repairing Edison incandescent lamps or lamps which infringe the Edison patent.

It was held that the Edison lamp being an organic whole, opening the glass bulb and reinserting a new filament really constituted the making of a new lamp, and consequently infringed the Edison master patent.

In this decision Judge Colt says in part:

> It is apparent that the defendants by substituting a new filament in the glass receiver and exhausting the air from such receiver produce a lamp in which all the elements but one (the leading-in wires) of the patented combination are used either in a new or reconstructed form.
>
> The lamp there produced is substantially a new lamp, and its voltage may be higher or lower than the old one. From the very nature of the Edison invention, I do not see how the glass bulb can be opened and a new filament inserted without making essentially a new lamp.

Trade Notice.

Owing to changes which have taken place in the corporation of Taylor, Goodhue & Ames within the past year the style of the firm is now changed to Taylor, Dee & Mack. On account of distrust with which corporations with limited capital are looked upon in certain quarters, Taylor, Dee & Mack will do business as a partnership and will assume all liabilities of the corporation of Taylor, Goodhue & Ames.

Electro - Medical Instruments.

A Resume of What Has Been Accomplished.

How Some Late Forms Came to be Adopted.

At the last meeting of the Electro-Therapeutic Association, which was held in Chicago during the past summer, it was a noticeable fact that a considerable portion of the business transacted consisted of the reading of reports of committees which had been formed to inquire into the merits and demerits of the electro-medical apparatus offered for sale by the various dealers. The Association listened to reports on standard coils, standard meters, electrodes, etc., and in fact on nearly all branches touching the mechanical end of electro-therapeutics.

The significance of this cannot be overestimated. The dependence of the physician on his instruments is a large factor in the cure of disease, and the fact that he has at last come to a realizing sense of the importance of selecting the very best that can be had is one which the manufacturer will do well to record.

It was not until comparatively recent years that electro-therapeutics has held the important position before the medical profession that it now occupies. The whole business was looked upon as quite outside the domain of the respectable practitioner, and its advocates labored under drawbacks and disadvantages to which they themselves contributed indirectly. It is to-day, however, a recognized branch of the profession and cannot be ignored.

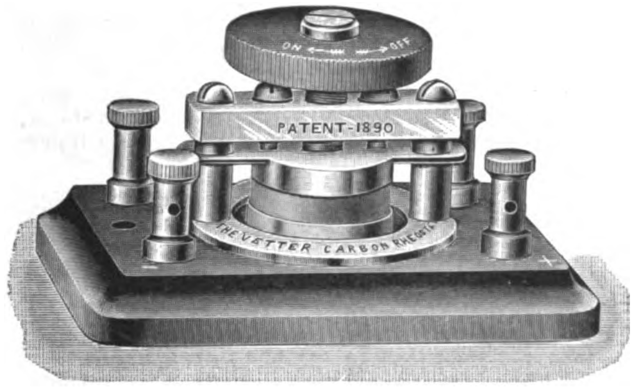

FIG. 1.

Much of this advancement has been made possible principally by the increasing excellence of the various kinds of electro-medical instruments; and while this is largely due to the physicians themselves, it owes its degree of perfection more particularly to the various dealers who, catering to the needs of the therapeutist, have made a special study of the mechanical part of the science.

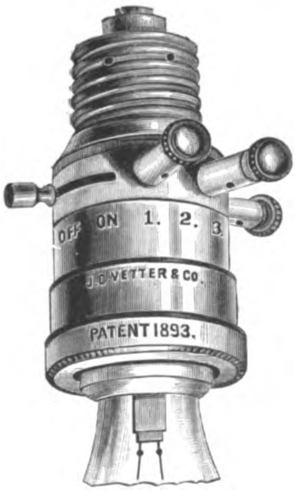

FIG. 2.

But in manufacturing for the medical profession the electrician must take cognizance of the fact that he has often to deal with forces quite outside the domain of ordinary electrics; if he does not, he may meet with hindrances which he may least expect to encounter.

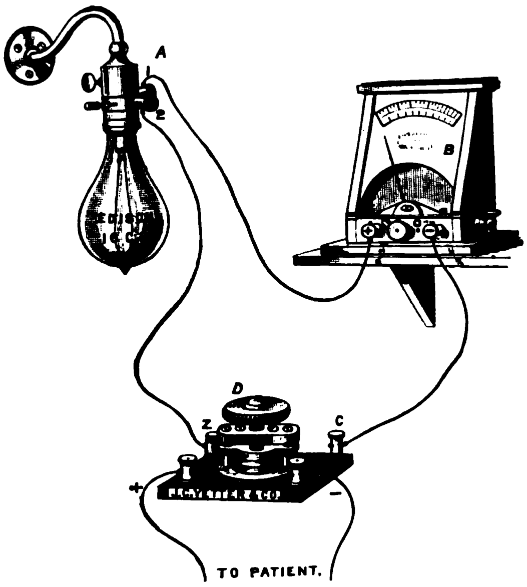

FIG. 3.

Hindrances such as these are among the least of the drawbacks to be expected by the instrument dealer, and the fact that he has risen superior to every one is good evidence of the amount of brains he has used and the ingenuity he has called forth in the pursuance of his calling.

But the greatest evidence of his brains and ingenuity is to be had from a view of the instruments themselves. In designing them the maker must remember one cardinal point. The average practising physician is seldom a practical electrician, even in the barest application of the word, nor will he be until some far-seeing philanthropist shall endow a "chair of electrical science" in our medical colleges. Hence the always to be desired feature is simplicity of construction.

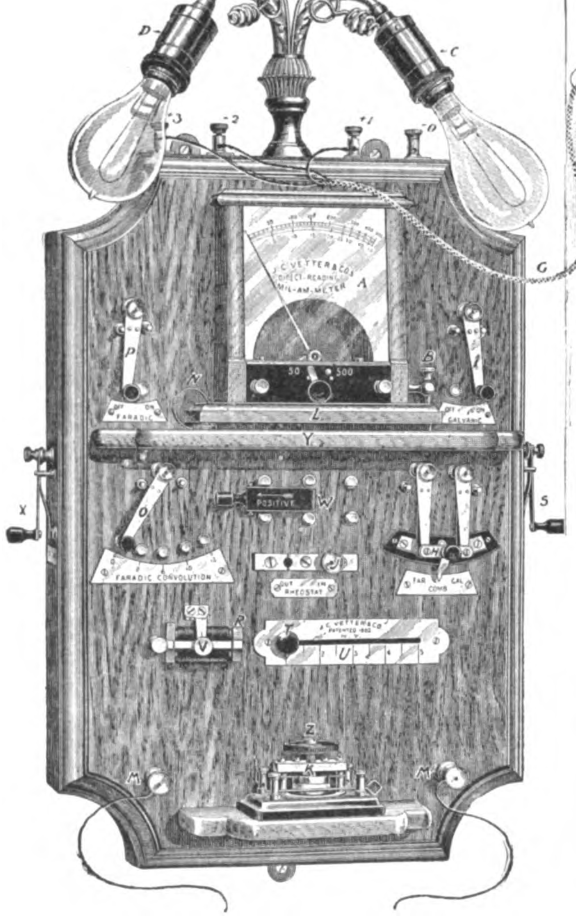

FIG. 5.

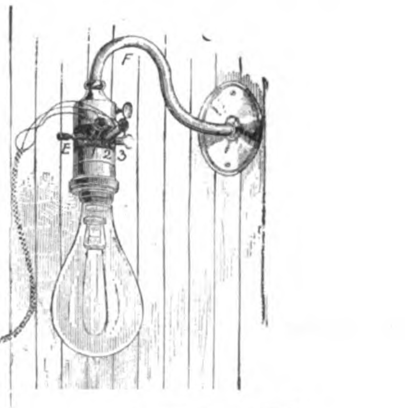

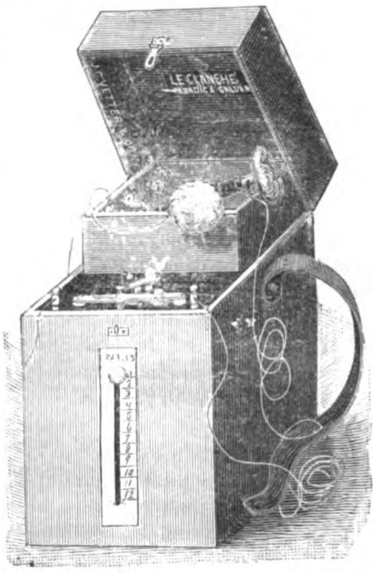

FIG. 4.

Some years ago, when the Electro-Therapeutic Association was in its infancy, an exhibition of apparatus was held at one of the meetings of the society. Most of the dealers were represented by some article or other, and a heterogeneous collection it was. The lesson evolved was, that the electrical-medical instruments of that period were decidedly complicated affairs. A wide-awake manufacturer of New York City, yet young in the field, and, be it said, with just as complicated instruments as his competitors, took advantage of the lesson there learned, and instituted a series of improvements which has resulted in as complete a line of goods as has yet been offered for sale.

The goods made by this firm have for their recommendation the simple plea of simplicity of design and application. The plan on which they were constructed is merely a result of proper appreciation of what the physician needs for the simple electrical treatment of disease.

Leaving out electrodes, which are elective adjuncts anyway to the general outfit, the electro-medical practitioner need take cognizance of but three propositions in considering the galvanic current. These are: the simplest way to generate it, the simplest way to control it, and the simplest way to measure it.

The simplest way to generate the current is by means of the cell, and the best cell for him to use inasmuch as it will cause a minimum amount of trouble, is one of some dry variety. The simplest way to control the current is to connect all the cells up in series and then regulate the total current by some form of rheostat. The simplest and only way to measure the current for medical use is with a direct reading milliampere meter.

A combination of these three points makes an ideal battery for medical use, and one which ought to appeal to the scientific spirit of the electro-medical man. In it are the dry cells enclosed in a portable case, and a controller which will allow of the current being used in any degree of intensity desired.

This controller (Fig. 1) is a unique instrument in itself. The fundamental principle adopted in its construction is the effect of variation in resistance which takes place in a quantity of carbon subjected to a change of pressure. A quantity of carbon in a finely divided state is placed in a small rubber cylinder which is between two metal plates forming opposing ends of a circuit. The lower plate is affixed to the instrument, and the other, traveling in upright guides, can be depressed by means of a screw with a fine thread so as to compress the carbon in the rubber cylinder. The broad claim on which the instrument was patented is, confining the carbon powder in a rubber pouch. The function of the latter is to hold the contained powder in the position necessary to keep up the contact between the poles, and to aid by its pliability the manipulation of the powder as the will of the operator causes the resistance to be diminished or increased.

The meter used in the first illustration is a vertical and direct reading one and possesses great advantages over horizontal indirect reading meters ; it does not depend upon terrestrial magnetism, which varies in different localities, but instead the pointer is controlled solely by the current passing through either of two coils, and the reading can be taken immediately the circuit is closed; no time is required for adjusting.

The best recommendation that this meter possesses is that at the last test of milliamperemeters conducted by the Electro-Therapeutic Association the instrument above was the only one out of six different styles that corresponded with the Weston standard.

If the practising physician lives in a town far enough advanced in civilization to possess an incandescent lighting plant, he need not bother with a battery. The latest method in these *fin de siecle* times is to take current from the street.

The adapter or incandescent current tap, shown in Fig. 2, enables him to do this without any trouble. It resembles an ordinary incandescent lamp socket. The instrument is a combination of binding posts and a switch. To use it, it is only necessary to detach a sixteen candle power lamp from its socket, put the adapter in its place, and afterwards screw the lamp into the adapter. Here is a battery indeed, and a source of unlimited supply of current, which never falls from grace by getting out of order, never spoils carpets with ruinous acids, and which cannot be borrowed "just for a couple of hours, you know," by a brother physician with predilections in this direction.

How the street current is coupled up, controlled and measured for medical work, is best shown in Fig. 3, which explains itself. The instrument is a *multum in parvo* of various electrical uses diversified to the greatest extent. It can be used to operate electric motors, charge storage batteries, extend a drop light, operate electric bells, miniature lamps, etc., and so on down a list too voluminous to detail.

In these days of scientific administration of the electric current—when medical men haggle over the therapeutic difference which may or may not exist between the administration of five or ten milliamperes of constant current, or as to whether the faradic coil should be made of coarse, medium, or fine wire, or combinations of all three, and other finely drawn distinctions of a like nature--the young physician is often at a loss to know just where he will enter the medico-electric arena. His hesitation generally ends by his entering through the door of Faradism armed with a battery whose vibrations are as irregular and uneven as the quakings of his own soul. He will find right here that his troubles have but just begun. Hence it is well if he select the very best weapon he can find. In the matter of faradic batteries there is much or little to say, depending on which text book he shall have studied, and how much he shall have been impressed thereby. We confess to thinking that the least there is said the soonest mended and many and various high sounding conclusions may not have to be recanted.

Meantime many good and definite results may be obtained from the use of Fig. 4, which will do everything the physician may desire in ordinary practice and is a valuable adjunct to clinical work.

The ideal outfit of all, however, is formed from a grand combination of all the foregoing. It is shown in Fig. 5. The whole affair is mounted on a handsomely polished base and combines a milliampere meter, a current controller faradic coil, DeWatteville switch for combining the galvanic and faradic current, pole changer and current tap. Switches for controlling these devices give the board a finished look and the incandescent lamps in the bracket above set off the affair in a brilliant manner.

The firm of J. C. Vetter & Company, who manufacture these goods and a picture of whose workshop is shown in our Frontispiece, are very well known in the medical electrical world, where they are acknowledged to have reached the top notch in the competition which has been going on for several years. They are now looking for new worlds to conquer and propose to enter the field of general electricity with their current tap as an opening wedge. They claim wonders for its future performance, and say it must ultimately be adopted wherever the incandescent current is known. They are established at 104 East Twenty-third street, New York City.

$50,000 May be Won.

Prize for a System of Street Car Traction.

It is Worth Working For, and the Time Limit should be Extended.

A prize of $50,000 has been offered by the Metropolitan Traction Company of New York City for a system of street car propulsion which will be superior or equal to the overhead trolley, without possessing the objectionable features of the trolley for crowded thoroughfares. The president of the company, Mr. John D. Crimmins, says that the general idea is to encourage some sort of underground trolley system.

The proposition was embodied in a letter sent to the State Board of Railroad Commissioners, and reads as follows :

> On streets where the lines are straight and the business is heavy the cable system is the most economical yet invented. For general use in a city, winding about through the streets following the routes of travel which the public wish to pursue, it is impracticable. You require straight routes for cable roads. We have in addition to the lines upon which the cable will be laid over eighty miles of street railroads now operated with horses all below Central Park. It is to these lines in particular that we now desire to direct your attention.
>
> Up to the present time the only system whose practicability has been demonstrated is the overhead trolley. We are well aware, however, that its application in the streets of New York would not meet with the approval of the community. What we most desire now is to hasten the development and perfection of a better system. We therefore submit the following proposition :
>
> First—We will set aside the sum of $50,000 to be awarded as a prize to any person who shall, before March 1, 1894, submit to your honorable board an actual working system of motive power for street railway cars demonstrated to be superior or equal to the overhead trolley.
>
> Second--The qualities necessary to meet this requirement shall be left to your decision; but with the present state of art, a system to win the award must necessarily approximate the trolley as a standard of economy in operation, but should be without the features objectionable to the public that are in it.
>
> Third—We shall exact no rights in the invention in return for the $50,000, and shall have nothing whatever to do with the making of the award further than to pay any expenses which your honorable board may deem it necessary or wise to incur, either in the employment of experts, the giving of hearings, or the conduct of experiments—this in order that no effort may be spared to achieve the desired result.

The proposition is made in perfect good faith, and inventors should attack the problem with renewed vigor.

Fifty thousand dollars is in reality a small part of the prize which awaits the inventor of the successful plan.

General News.

What is Going on in the Electrical World.

Washington, D. C.—$200,000 is to be expended in supplying an electric light plant for the Capitol and the new Congressional Library Building.

Griffin, Ga.—This city has voted to issue bonds to the amount of $16,000 to be expended on an electric light plant to be owned and controlled by the city.

Washington, Pa.—The electric street railroad, which has been in the hands of a receiver, has suspended operations, and will be sold by order of court.

Gainesville, Tex.—The city council has made a contract with a new company for a system of electric lights. The plant is to be completed within six months.

Green Island, N. Y.—A settlement has been effected in the matter of the electric light works, and it is probable that New York men will purchase the plant and operate it.

Natick, Mass.--The Natick and Cochituate Electric Railway Company has been granted a charter to run their tracks through Wellesley and Wellesley Hills to Newton Lower Falls. The company will lay the tracks in the spring.

Prairie du Chien, Wis.—The council has granted a ten-year franchise to an electric light company whose present offiers are : Will Thompson, president; Ira D. Hurlbut, vice-president; A. I. Heiman, treasurer; H. Bisbee, secretary.

Chicago. — The National Thermograph and Electrical Company, of Chicago, whose capital is $500,000, manufacturers of a thermograph used in refrigerator cars to register the temperature each hour in the day, have decided to remove their plant to Rockford.

Hartford, Conn.—Both branches of the common council have adopted the report of the rapid transit committee, giving the Hartford Street Railway Company permission to equip with the trolley the Parkville, Lafayette street, Farmington avenue and Asylum avenue lines.

Canton, Ohio.—The city council has under consideration the building of an electric light plant, to be owned and managed as a branch of the city government. The gasoline, gas and electric light companies, which secure about $20,000 a year out of the city, will contest the project.

Richmond, Va.—At a meeting of council last week, Mr. Turpin offered a resolution instructing the committee on streets to confer with the street railway authorities as to having the cars on the Broad street line propelled by electricity. The resolutions were referred to the committee on streets.

New York.—The Gas Commission met in the Mayor's office on the 15th, and awarded most of the contracts for lighting the city with gas and electricity to the same companies and at the same price as that of last year. Some of the electric companies wanted an increase, and their bids were laid over for consideration.

Toledo, Ohio.—The wood carving room at the Manual Training School is now illuminated by electric lights. The dynamo furnishing the current is entirely the work of the students, who also strung the wires and arranged the whole lighting system under the direction of Superintendent Waite.

Whitestone, N. Y.—The trustees of this Long Island village have granted a franchise to the College Point and Whitestone Street Railway Company, recently incorporated, to operate an electric road on the streets of the village. A similar application will be made to the College Point trustees to lay the tracks on some of the principal streets of that village.

Paterson, N. J. — Twenty machinists employed at the Edison Electric Works have struck because the company refused to grant them their request for an advance of 25 cents a day. A month ago the men were receiving $2.75 a day, and claim they were reduced to $1.75. After working a week or two at these wages they concluded to ask for an advance to $2.00.

Freeport, Ill. — The Freeport City Street Railway has been purchased by Percy Thompson & Company, bankers, of New York City, and their associates. A new company has been formed with a capital stock of $150,000, and will at once change the present motive power to electricity. The new company will immediately construct and operate eight miles of electric road.

Topeka, Kan.—D. E. Kimball, of this city, has returned from Chicago, where he has been interesting capitalists in his new electric underground conduit system, which is intended to do away with the overhead trolley system of electric railways. A company has been formed in Chicago to manufacture the conduits, and they expect to begin work about the 1st of March.

Springfield, Mass.—The Springfield Street Railway Company has given notice to the United Electric Light Company that the present contract under which the latter furnishes power for running the street railway cars would be terminated December 1, 1894. The railway company will erect a power house at an early date and put in a plant as perfect as possible in every appointment.

New Orleans.—According to the *Picayune*, Mrs. F. W. Tilton, of Canal street and University place, has the proud gratification of knowing that she has the first electrical piano received in the South. It was delivered to her two weeks ago. -The St. Charles Street Railroad Company have applied to the city council for permission to change the motive power of their road to electricity.

Indianapolis, Ind.— A dispute has arisen between the street car company and the Indianapolis Light and Power Company as to the contract for furnishing electric power. The street car company insists that the contract calls for six hundred horse power at the generator, while the power company claims that the strength of six hundred horse power is to be furnished at the engine.

Rochester, N. Y.—Dr. Charles Forbes has been engaged to deliver a course of ten University Extension lectures on "Electricity" at the Free Academy Hall here, beginning with the first Tuesday in January. The lectures are to be illustrated by experiments, and the aim will be to present and illustrate the elementary principles very clearly, so that the great modern applications of electricity may be understood.

Liberty, N. Y.—It is understood here that S. P. Kellogg and J. C. Clirehugh, of Elizabeth, N. J., backed by competent capitalists, purpose, under certain conditions, building a trolley road from Liberty via Stevensville, to White Lake, and also a road from Stevensville, by the way of White Sulphur Springs and Youngsville, to Jeffersonville. The principal power station would be at Stevensville. It is said the entire twenty miles can be in running order by July 1.

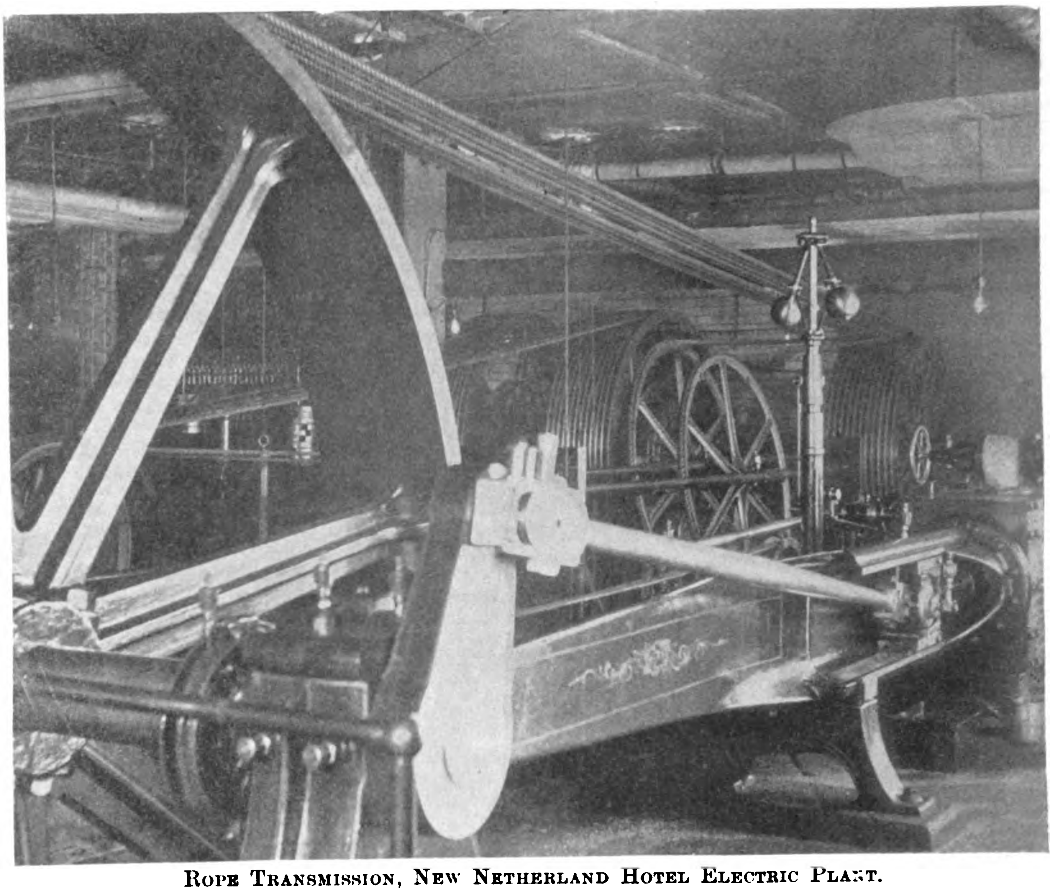
Kingston, N. Y.—The *Freeman* says that a contract has been closed with New York parties for the construction of a trolley line from this city to Lake Katrine. The road will be operated by a stock company to be known as the Lake Katrine Electric Railroad Company, and steps have been taken to have it incorporated. The majority of the stock will be held by the Lake Katrine Hotel Corporation, the rest having already been sold to New York parties.

New Haven, Conn.—The incorporators of the West Shore Electric Railroad have made arrangements to build the line at an early day. The capital stock is $50,000, and the charter allows the company to build from the termination of the Winchester Avenue Road at Savin Rock to Merwin's Point, a distance of about 3½ miles. The incorporators are James D. Dewell, Henry Sutton, Israel A. Kelsey, C. K. Bush and W. Wallace Ward.

Nashville, Tenn.—At the annual meeting of the stockholders of the United Electric Railway Company on the 12th inst. the following officers were elected: T. W. Wrenne, president; M. M. Gardner, vice president; E. G. Connette, general manager; G. W. Cunningham, secretary and treasurer. The directors are: Thos. W. Wrenne, H. H. Buckner, R. W. Turner, M. M. Gardner, James P. Byrne, Andrew Marshall, J. H. Bruce, J. P. Williams, James Simmons, W. C. Dibrell, T. O. Morris and J. C. Bradford.

Battle Creek, Mich.—The Chicago *Inter-Ocean* publishes the following dispatch from Battle Creek: "Seth M. Carter, of Auburn, Me., one of the bondholders of the electric street railway here, is in the city looking after his interests. He says that the purchasers of the bonds were swindled. It was represented that the road was paying a dividend when it had never paid expenses. The bondholders, cannot, he says, operate the road until the United States Court gives them possession and the council has started proceedings to take back the charter."

Pittsburg, Pa.—The largest dynamo ever made was finished on the 12th inst. at the Allegheny shops of the Westinghouse Electric and Manufacturing Company, and subsequently satisfactorily tested. It is one of four built for the Louisville, Ky., Gas Company, and has a capacity of 10,000 incandescent lamps. It weighs fifty tons and has an armature 20 feet in diameter. This is four feet greater than the armature on the big dynamo at the World's Fair. It will make ninety revolutions per minute. The dynamo will give the same power as the World's Fair machinery, but will take up less floor-space. It will be operated by a one thousand horse power engine. The shaft of the engine will connect with the dynamo, no belting being required.



Rope Transmission, New Netherland Hotel Electric Plant.

Bridgeton, N. J.—Two companies have just been formed here to build new trolley railways to be operated in connection with those already in use. One company is the Bridgeton, Cedarville and Port Norris Railway Company, which proposes to establish a line from South Bridgeton for a distance of about nine miles, passing through Fairton and Cedarville and eventually connecting Port Norris, the heart of the oyster growing region. The other company is the West Side Railway Company, which proposes to build a road in the Third Ward of Bridgeton, lying west of the Cohansey River.

Baltimore, Md.—The Thomson-Houston Company has practically completed the motors and generating machinery for running trains through the Belt tunnel by electricity. The electric company is to put overhead wires in the tunnel, as the trolley system is to be used. The rails of the roadbed will be connected with wire to make a return current of electricity and so to complete the circuit from which the electric engine will obtain its power. The Baltimore and Ohio Company is to select a site and build the power house for the electric plant with which the experiment is to be made.

Niagara Falls, N. Y.—Major George B. B. Burbank, chief engineer of the Cataract Construction Company, said to a reporter last week: "Our power house for the 5,000 horse power dynamos is nearly completed. The immense steel electric crane has been placed in position within the building and the heavy stone walls are up. The foundations for the great turbines will be completed this week. These wheels are ready for shipment at Philadelphia and will probably be ordered next week. The big penstocks are already here. The other works of the Cataract Construction Company, such as the new village, the railroad, the water works, electric companies and others, are progressing fast towards completion. Niagara Falls is fast preparing to furnish the world with electricity."

A New Style of Rope Transmission.

The New Netherland Hotel of this city contains an electric plant in which a somewhat unique system of transmission is employed. The equipment consists of two Corliss engines of 325 and 250 horse power respectively, one of which is placed at either end of the room, and is connected to a line shaft extending along the length of the room in front of the engines, and four dynamos, three of 100 K. W. capacity and one of 60 K. W. The novelty of the plant lies in the system of rope belting used.

The driving wheel of the largest engine is grooved for twelve strands of rope and that of the smaller engine for ten strands. Both of these pulleys have two separate rope belts of six and four continuous strands respectively, by which the line shaft is run. As the dynamos are driven by means of rope it enables them to be placed quite close up to the line shaft, which would be impracticable with belts, thus saving valuable space. Careful tests have failed to detect any slippage whatever, and there is an absence of all noise and vibration. There is not a foot of belt used for transmitting power in the plant.

Another point to be noticed is the tension device. One strand of each multiple rope passes over a wheel on a traveling carriage, which keeps the strain on the ropes constant for any power regardless of the variations in length of rope due to moisture or stretch caused by use. It takes up any slack caused by a sudden increase of load, or gives back slack when the load is reduced. There are two of these tension carriages to each machine, as shown in the accompanying engraving. There is also a high speed engine connected to a 100 K. W. dynamo in the same manner, and the whole plant is contained in a remarkably small space, due to the short distance between centres which may be used with this system.

The apparatus was manufactured and put up by the Link Belt Company of New York and Philadelphia, and has given excellent satisfaction.

Adams Electric Company.

Mr. A. D. Adams resigned his position as electrician and manager of the Commercial Electric Company, December 1, and has formed, with others, the Adams Electric Company, for the manufacture of his improved dynamos and motors at Worcester, Mass.

Mr. Adams's new machines will be of the same general type as his former ones, will embody the well-known forged iron field magnet construction, and several important improvements.

Realizing that most armature burn-outs are due to the destructive action of heat on the cloth and paper usually employed to insulate armature cores from their windings, Mr. Adams will use a fire-proof material for the insulation of all armature cores in his new machines.

The line of motors and dynamos at present manufactured will cover the usual sizes, from 1 to 25 K. W.

A large, well-lighted shop is being fitted up at 100 Beacon Street, Worcester, for the manufacture of the above machines, and shipment of any of the sizes named can be made during January next.

The encouraging fact is reported that orders for several machines have already been received.

THE NATIONAL ELECTRIC COMPANY.

Special Announcement.

The National Electric Company of Eau Claire makes the following announcement of its plans and purposes:

"Having purchased the entire plant and stock formerly operated and owned by the National Electric Manufacturing Co. we take pleasure in announcing to our friends and to those interested in electric lighting that we are prepared to furnish alternating and direct current apparatus, multipolar power generators and motors, transformers of any capacity and voltage, as well as other electrical apparatus and appliances, promptly upon receipt of your orders.

"To the former patrons of the National Electric Manufacturing Company we extend a cordial greeting, and solicit a continuance of your patronage.

"To others we extend a similar greeting, and will take pleasure in quoting prices and furnishing other information desired relative to our apparatus promptly upon application. Sincerely yours,

"NATIONAL ELECTRIC COMPANY.

"Eau Claire, Wis., Dec. 8, 1893."

Removal Notice.

The Phosphor-Bronze Smelting Company, Limited, of Philadelphia, have removed their offices to No. 2,200 Washington avenue, where they have largely increased facilities for the manufacture of their famous Elephant brand phosphor-bronze ingots, castings, wire sheet, rods, etc.

Commercial Note.

The Metropolitan Electric Company, Chicago, have added another very important name to their list of specialties—a new incandescent lamp. This is to be known as the "Metropolitan" and embodies the latest improvements in incandescent lamp manufacture. By the utilization of new and improved methods, this lamp offers very high efficiency, and will maintain its full candle power throughout its entire life, two elements of value in incandescent lamps that cannot be over-estimated. The lamp has been patented, and the Metropolitan Company will guarantee that it is non-infringing in every respect. It is now ready for the market, and orders can be filled promptly.

INCORPORATIONS.

The Milford Electric Light Company, Milford, N. H.—to generate electricity for light, heat and power by steam or water, furnish and distribute the same through the streets of Milford and neighboring towns; takes franchise heretofore held by the Souhegan Electric Light and Power Company. Capital stock, $50,000. Promoters: Henry A. Burnham, Gloucester, Mass.; Henry C. Buck, Winchester, Mass.; Frank T. Clark, Boston, Mass.

The Glenwood and Dravosburg Electric Street Railway Company, Pittsburg, Pa.—to construct and operate an electric railway in Allegheny County, Pa. Capital stock, $27,000. Promoters: Ira J. Wilson, James P. Wilson, Homer H. Swaney.

The General Manufacturing Company, Bound Brook, N.J.—to manufacture, buy, sell and deal in sewing machines, electrical devices, tools, machines and machinery. Capital stock, $2,500,000. Promoters: Abnes W. Pollard, Louis A. Pollard, Brooklyn, N. Y.; S. O. Loughlin, N. Y. City, N. Y.; Edward C. Kidder, Williamsbridge, N. Y.; Jos. B. Cleaver, Bound Brook, N. J.

The Chamberlain Electric Light and Power Company, Chamberlain, S. D.—to produce electric light and power. Capital stock, $200,000. Promoters: H. H. Natwick, J. L. Stene, M. E. Distad.

Fuller Incandescent Heat and Light Company, at Chicago. Capital stock, $1,000,000. Incorporators: J. T. Kreitzinger, C. E. V. Akerberg, M. F. Gallagher.

The Belleville Electric Railway Company have filed articles of incorporation at Springfield, Ill. It is proposed to build a railroad from Belleville to East St. Louis. The capital stock is $300,000. The incorporators and first board of directors are J. H. Atterbury, John W. Griswold and R. Ross, of Litchfield; John J. McLean, of Hillsboro, and Paul W. Abt, of East St. Louis.

Universal Electric Heat and Light Company, Chicago. Capital stock, $100,000. Incorporators: J. T. Kreitzinger, C. E. V. Akerberg, M. F. Gallagher.

Turney Electric Manufacturing Company, Chicago. Capital stock, $75,000. Incorporators: Eugene T. Turney, Walter H. Crowdus and William E. Mason.

The Rockaway Electric Light and Power Company, Rockaway, L. I.—to furnish electric light, etc. Capital stock, $20,000. Alderman Samuel Myers, of Brooklyn, is president, and John A. Seely treasurer.

Slocum Electric Company, at Albany—to deal in and manufacture automatic machines. Capital stock, $50,000. Directors: Paul C. Grening, J. J. Vail, Harry F. Slocum.

The Chesapeake and Ohio Transportation Company, Baltimore—organized for the operation of canal boats by electricity. Capital stock, $250,000. Most of the shares are held by canal operators in Western Maryland.

The Cortland Fire Alarm Company, Toledo, Ohio—to manufacture, buy and sell all kinds of electrical appliances, wire buildings, operate Cortland fire alarm system, etc. Capital stock, $100,000. Promoters: Geo. J. Sherman, Albion E. Lang, Jas. A. Corbusier, Calvin Barker, Harvey Cortland.

The National Electric Company, Eau Claire, Wis.—to purchase and operate the plant formerly owned by the National Electric Manufacturing Company, of Eau Claire, Wis. Capital stock, $50,000. Promoters: Peter Truax, W. A. Rust, G. T. Thompson.

Standard Electric Time Company, of Laconia, N. H.—to construct, maintain and operate electric time clocks and signals, furnishing electric time and other purposes. Capital stock, $1,200. Promoters: O. W. Tibbetts, C. W. Tyler, Dennis O'Shea.

The Pioneer Electric Power Company, Salt Lake, Utah—for the acquiring, storage and utilization of the waters of Odgen River for the purpose of deriving power therefrom, and the acquirement of land and the use of water for irrigation; the use of the power for manufacturing, for railways, heating, lighting and other uses, either by electric transmission or otherwise; the acquirement of franchises in cities and towns to operate railway lines, water and power plants, heating, lighting, etc.; the business of operating said plants and the sale of power to other corporations or individuals and the use of the water for irrigation, domestic and other uses. The officers are George Q. Cannon, president; F. J. Keisel, vice-president; C. K. Bannister, secretary and treasurer, and Frank J. Cannon, general manager. A deed has been placed on record in Salt Lake City from C. K. Bannister and wife to the Pioneer Electric Power Company of the waters of Ogden River, the consideration being $1,000,000.

The Berkshire Electric Light, Heat and Power Company has been organized at Monterey, Mass. The following directors were chosen at a meeting of the stockholders: John L. Dodge, G. A. Stevens, W. Hyer, Samuel Camp, J. A. Brewer, G. Otto Eltrich and O. W. Lane. W. Hyer was appointed treasurer and secretary. The plant will be located at Hartsville. The company expect to have their lights installed in about two months, although considerable trouble is expected from the old company.

The Prescott Electric Light and Power Company, Prescott, Ariz.—to manufacture, create, supply, furnish, sell and distribute electricity for light, motive power, heating and any and all purposes for which electricity can in any way or method be used, to build, construct, maintain and operate electric street car railways and telephone lines, to manufacture, construct, purchase and sell any and all classes of electrical appliances and fixtures, etc. Capital stock, $25,000. Directors: F. L. Wright, George W. Mittendorf, Henry K. Behn.

The Non-Electric Fibre Manufacturing Company—to manufacture materials for insulating electric conductors, wires and other electric devices. A plant for such manufacture will be established in either New York or Brooklyn. Capital stock, $250,000. Directors: Mark L. Deering and Royal C. Peabody, of Brooklyn; William J. Maidhof and William J. Comly, of New York; and Edward Lyon, of Orange, N. J.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 5, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

510,061. Conduit Electric Railway. William R. De Voe, Shreveport, La., assignor of seven-twelfths to C. W. Dawley, Dallas, Tex., and Patrick B. Cash, Shreveport, La. Filed June 12, 1893.

510,142. Conduit Railway-Trolley. Paul C. Just, Chicago, Ill. Filed Jan. 31, 1893.

510,201. Trolley and Trolley-Switch. David V. B. Smart, Troy, N. Y. Filed Feb. 1, 1893.

510,217. Support for Trolley-Wires. James E. Walker, Denver, Colo. Filed May 3, 1893.

510,384. Electrically-Operated Railway-Switch. Henry L. Falco, Brooklyn, N. Y. Filed Jan. 26, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

510,018. Incandescent Electric Lamp. Henry Green, Hartford, Conn. Filed Oct. 17, 1892.

510,095. Shade for Electric Lamps. George F. Seavey, Boston, Mass. Filed July 23, 1892.

510,188. Electric-Lighting System. George B. Pennock, Chicago, Ill. Filed Feb. 20, 1893.

510,260. Electric-Arc-Lighting System. Daniel Higham, Boston, Mass. Filed July 6, 1893.

510,303. Arc-Lamp Support and Connection. Lucius E. Thompson, Dunkirk, N. Y. Filed May 10, 1893.

510,317. Bracket for Incandescent Lights. Charles M. Berry, San Francisco, Cal., assignor to Ellsworth D. Middlekauff, same place. Filed June 14, 1893.

MOTORS, DYNAMOS, ETC.

509,953. Regulator for Dynamo-Electric Machines. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed Dec. 10, 1888.

509,954. Dynamo-Electric Machine. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1889.

509,955. Regulator for Dynamo-Electric Machines. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed June 1, 1889.

510,059. Electric Motor. Arthur H. Beard, Manchester, Ala. Filed June 10, 1892. Renewed Oct. 27, 1893.

510,102. Electric Motor or Dynamo. Herman K. Thiel, Alpena, Mich. Filed April 10, 1893.

510,367. Reciprocating Electric Motor. Arthur R. Roe, Duluth, Minn., assignor to the Electric Motor Company, same place. Filed Nov. 21, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

509,873. Signaling-Telegraph. Michael J. Burns, Lowell, Mass., assignor to the Gamewell Fire Alarm Telegraph Company, of New York. Filed Nov. 25, 1892.

509,956. Annunciator for Telephone-Switchboards. Chas. E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 2, 1893.

509,934. Telegraph-Key. Josef Steiner, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed May 8, 1893.

509,965. Telephonic Transmission. John S. Stone, Boston, Mass., assignor to the American Bell Telephone Company, same place. Filed May 22, 1893.

510,002. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed July 25, 1891.

510,003. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed Jan. 22, 1892.

510,004. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed Jan. 22, 1892.

510,005. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed April 14, 1893.

510,006. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed July 22, 1893.

510,007. Telegraphy. Patrick B. Delany, South Orange, N. J. Filed Jan. 22, 1892. Renewed Sept. 25, 1893.

510,195. Automatic Telephone Exchange System. John Serdinko, New Braunfels, Texas. Filed April 22, 1893.

510,209. Electric Telegraphy. Charles Thom, Jr., Brooklyn, N. Y. Filed Feb. 2, 1893.

ELECTRICAL MEASURING INSTRUMENTS.

510,074. Electrical Measuring Instrument. Otto T. Louis, Philadelphia, Pa. Filed March 28, 1893.

510,177. Combined Ammeter and Voltmeter. Edward W. Jewell, Wheaton, Ill. Filed July 1, 1893.

MISCELLANEOUS.

509,932. Testing Apparatus for Multiple Switchboards. Frank R. McBerty, Downer's Grove, assignor to the Western Electric Company, Chicago, Ill. Filed Feb. 7, 1893.

509,985. Thermometric Alarm. Otto Weyrich, Elberfield, Germany, assignor to Isidor Cahn, same place. Filed May 16, 1893.

510,026. Non-Conducting Covering. Henry W. Johns, New York, N. Y. Filed Feb. 15, 1893.

510,041. Overhead Traveling Crane. William H. Morgan, Alliance, Ohio, assignor of three-fourths to Thomas R. Morgan, Sr., Thomas R. Morgan, Jr., and John R. Morgan, same place. Filed May 28, 1892.

510,048. Electrical Apparatus for Operating Dental Implements. Oscar H. Pieper, San Jose, Cal. Filed Nov. 25, 1892.

510,083. Cash Register, Indicator and Recorder. William T. McGraw, Plymouth, Mich. Filed June 19, 1893.

510,113. Emergency Wagon for Electric Line Work. Edwin S. Breed, Waterbury, Conn. Filed May 15, 1893.

510,115. Electric Fire Alarm. Milton C. Cantrell, Springfield, Mo. Filed March 2, 1893.

510,156. Circuit Breaking Apparatus. John Burry, New York, N. Y. Filed July 14, 1893.

510,276. Process of Electrolytically Decomposing Fused Metallic Chlorides. Farnham M. Lyte, London, England. Filed June 30, 1893.

510,320. Magneto Apparatus. Arthur F. Boardman, Somerville, assignor of one-half to John Tyler Hicks, Boston, Mass. Filed Sept. 20, 1893.

To Inventors and Others.

United States and Foreign Patents Procured.

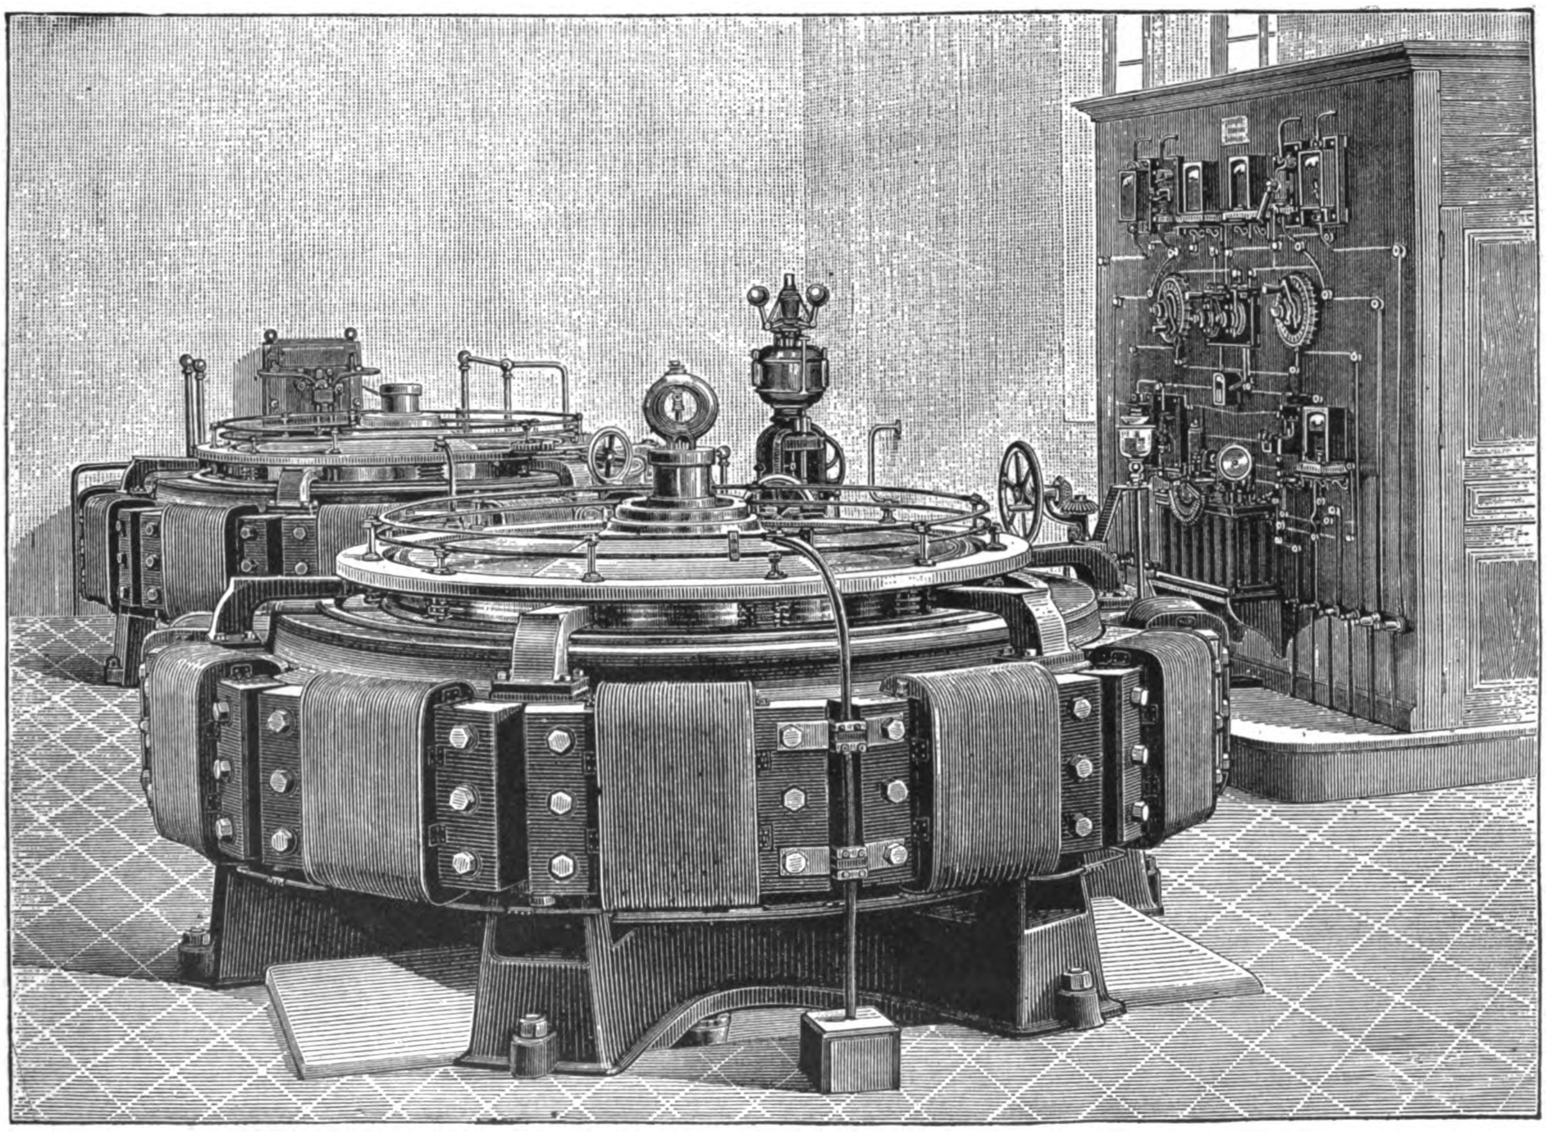
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. DECEMBER 27, 1893. CHICAGO. No. 24



THE SELEVE, SWITZERLAND, HYDRAULIC STATION. (SEE PAGE 282.)

A Swiss Railway Plant.

Seleve, Switzerland, which is a popular resort for tourists both in summer and winter, has an electric railway driven by water power, a description of which is given in *L'Industrie Électrique*. The power is derived from the river Arve, upon whose bank the power house is situated. A channel has been cut across a narrow point of rock around which the river makes a sharp turn. This channel is capable of supplying 20 cubic meters of water per second, which is the minimum supply of the river in winter. A dam at the head of the channel secures a fall of three meters, giving a capacity of about 600 horse power for the plant.

The building, which is well constructed, has beneath it three cemented chambers, two of which contain 250 horse power turbines with vertical shafts and running at but 45 revolutions per minute. The mechanical part of the plant was constructed by J. J. Rieter & Company, of Wintherthur. One of these turbines is sufficient ordinarily for the work during the week, but the number of visitors on Sundays and holidays makes it necessary to employ both machines, and a third one is to be added to the plant for a reserve, the place for which was provided in advance.

A small turbine of 20 horse power running at 82 revolutions is used to drive a Thury dynamo giving 140 amperes at 110 volts. This current is used to excite the fields of the large horizontal dynamos, shown in the Frontispiece. The large Thury machines have an outside diameter of 3.2 meters and the total weight of each is 19 tons. The armatures are mounted on the vertical shaft of the turbines and the field has 12 poles which rest on a special flooring. These dynamos furnish 275 amperes at 600 volts, and as the speed of the turbines is constant the regulation is effected by an automatic Thury regulator in the exciter circuit.

General Electric.

Notes and Comments from Various Sources.

The stockholders of the Atlanta street railway are invited by circular to pay $17.50 per share to wipe out the floating debt, for which they are offered consolidated and income bonds. Bondholders are also asked to accept a scaling of the 6 per cent. gold bonds to 3 per cent., beginning January 1, 1894, for two years, and 5 per cent. thereafter. Thomson Houston people were among the promoters of the street railway undertaking.—*Boston Herald.*

Sales of General Electric were accompanied by renewed rumors of some kind of reorganization in the business; among them a story that the present company will sell the plant at Lynn, and the motor patents to the old Thomson-Houston interests and confine its business wholly to electric lighting.—*N. Y. Evening Post.*

Howell Osborne has had nothing, positively nothing, to do with the manipulation or purchase of General Electric.—*Town Topics.*

It is reported from Albany that the Schenectady Works will start up on full time January 1. Several carloads of patents, in addition to much machinery, have been received there from the Lynn Works.

Do Coming Events Cast Their Shadows Before?

Boston is again enthusing on this property (G. E.) Yesterday's despatches from that city stated that the insiders aver that the report for the year ending February 1 will show a very good financial position, and some assert that before July 1, 1894, the General Electric Company will not only be out of debt directly, but indirectly, with all endorsed bills receivable paid.—*Wall Street News.*

Every large corporation which has gone into the hands of a receiver during the last six months has issued statements similar to the above within ten days previous to the collapse.

Recollections of Werner Von Siemens.*

V.—Active Business Life Begun.

Summary of Inventions Previous to 1850.

For publication in scientific and technical journals there was no time; even patents were taken out only in rare cases. There was then no German patent rights, and in Prussia patents, given almost arbitrarily for from three to five years, were therefore without practical value. The inventions and improvements proceeding from us at that time therefore in the majority of cases lack the attestation of their origin by publication or patent.

A conspicuous illustration of this occurred a few years ago. There turned up somebody in the United States who asserted that he was the inventor of underground conductors, especially of those insulated by gutta-percha, and who tried after the lapse of more than a quarter of a century to obtain a patent for the same, which threatened considerable loss to the large American telegraph company.

The company sent a special commission headed by their director, General Eckert, to Berlin, to search for verification by printed publications that in 1846 I had already introduced wires with gutta percha insulation. To their written enquiry I was obliged to reply that nothing was to be found in print on the subject, but that the official records of the Staff Commission and of the subsequent Telegraph Board contained proof complete.

This however did not suffice for the lawsuit. The Americans chose another very practical way to procure printed information on the matter. They advertised in several German papers that they would pay a considerable sum for a description, printed in 1847, of the underground telegraph lines laid on the track of the Anhalt Railway. That succeeded. After a few days there arrived from different places in Germany newspaper cuttings with the desired description. The commission congratulated me as the undoubted inventor of the gutta-percha conductors and traveled home.

The proposed publication of the results however never came off, because, it is said, in the meantime a compromise with the reputed inventor had brought greater profit to the company.

In Germany, after the construction of the lines to Frankfort-on-the-Main and Cologne, the system of underground communications had become the fashion. Not only were the Government telegraph lines from Berlin to Hamburg, Breslau, Königsberg and Dresden constructed underground with unprotected wires, buried at a depth of two feet, but even the railways preferred to lay such underground lines, although the indications of the speedy destruction of these lines increased daily. In particular the destructive action of rats and mice became more evident —especially on the first lines, which were laid in the sandy railway embankments one and a half to two feet deep. The wires laid over two feet deep were indeed at first exposed to no such destruction; but subsequently it occurred even in them.

I then believed that a coating of lead would completely cope with this evil. To coat the wires with lead I proceeded at first in the following manner: Leaden tubes were straightened out, then a hempen band was blown through them by means of a bellows, and with its help the conducting wire insulated by gutta-percha was drawn into the tube. Thereupon the tube was passed through a draw-plate, in order to effect a firm attachment to the insulated layer of the conductor. We afterwards succeeded in pressing the leaden tube directly round the insulated wire when the lead had exactly acquired a certain temperature and permanently retained it. The difficulty of continually controlling this temperature I overcame by a thermo-electric arrangement.

Such conductors, surrounded by lead casing were frequently furnished by Halske and me in the beginning of the fifties. So among others in the telegraphic system, which we set up for the police service and the fire brigade of Berlin. These lead lines acted quite satisfactorily for a long series of years. They were then gradually replaced by cable conductors, yet lead conductors have remained in excellent condition to the present day, after the lapse of 40 years. Only where the lead has come in contact with decaying matter in the soil, whereby the formation of acetate and carbonate of lead is facilitated, is it liable to rapid destruction.

The just mentioned police and fire-brigade telegraph was intended to unite fifty stations in different parts of Berlin with the central office of the police department and the central office of the fire-brigade, so that the report of fire might be simultaneously communicated to all stations, whilst the police reports were only to be received and comprehended at the central police bureau. Our arrangement solved this interesting problem very satisfactorily and worked for over twenty years well and accurately, but then succumbed to the simpler Morse system.

Morse's writing telegraph first became known in Germany through a Mr. Robinson who, in the year 1850, gave exhibitions with it in Hamburg. The simplicity of Morse's apparatus, the relative facility of acquiring the alphabet, and the pride which fills every one who has learnt to use it, and causes him to become an apostle of the system, have in a short time ousted all dial and older letter-printing apparatus.

Halske and I at once perceived this superiority of the Morse telegraph, resting on manual dexterity, and made it therefore our task to improve and perfect the system mechanically as far as possible.

We gave the apparatus good wheel-works with automatic regulation of the velocity, a reliable magnetic system, sure contacts and commutators, improved the relays, and introduced a complete system of translation. This consisted in an arrangement whereby all the currents circulating in a telegraphic circuit were automatically transferred to a neighboring circuit provided with its own battery, so that the whole line was divided into several separate closed circuits, but yet without the assistance of the telegraph clerks of the intermediate stations communications could be directly held between the terminal stations.

Such a system of translation I had elaborated as early as 1847 for my dial and printing telegraphs, and had laid before the Staff Commission an apparatus constructed by myself for this purpose, the so-called go-between (relay). Translation however only attained its full importance through the application to the Morse apparatus; it came into use for the first time on the Berlin-Vienna line, which was provided in Breslau and Oderberg with translation stations. It may be here mentioned that the contrivance was subsequently very considerably improved by Prof. Dr. Steinheil, the then Director of the Austrian telegraphs, by fitting an automatic contact to the wheel-work.

My time on entering the business was entirely claimed by constructive work for the factory, and by the laying down of numerous railway telegraph lines undertaken by my firm. Still in the winter of 1849-50 I found a period of leisure, which I employed in putting together for publication my experiences on telegraphic communication and apparatus. In April, 1850, I laid my work, with the title "*Mémoire sur la télégraphie électrique*," before the Paris Academy of Sciences. This had been rendered possible to me through a lucky accident, which enabled me to meet in Paris my friend Du Bois-Reymond, who intended to present a work of his own to the Academy, and gave me his friendly assistance for the French remodelling of my essay. I still remember with great satisfaction the stimulating, and to me extremely interesting and instructive, time of this four weeks sojourn in Paris, the living together with friend Du Bois, and the intercourse with the most celebrated Paris *savants*. To the members of the committee appointed by the Academy for considering my work belonged Pouillet and Regnault. The report on my memoir was read by Regnault at a sitting of the Academy, to which Du Bois and I had received formal invitations. Leverrier appeared as opposer, and defended the electro-chemical telegraph of Bain, which had likewise been presented to the Academy. The presiding *secrétaire perpétuel*, Arago, however, cut short Leverrier's opposition by moving the thanks of the Academy for the memoir and its reception in the "*savants étrangers*."

---

* Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

This public testing of my literary firstling in the telegraphic domain by famous members of the first scientific tribunal in the world produced a deep and very stimulating impression upon me. Many reasons can be offered against such an official trial of scientific and technical performances, which supplies a kind of hall mark and may easily be very injurious to the free unfolding of science; it is indeed only admissible under full control by the publicity of the *séances*—can then however be very useful and stimulative.

I content myself here with a concise summary of the most important scientific and technical improvements, the priority of which is secured to me by that publication:

Introduction of the automatic break of the electric current at the end of every movement of the armature through a predetermined distance. Or one may put it thus: increase of the movement of the Neef hammer by a mechanism answering to the slide of the steam-engine. All automatic electric alarums without clockwork and many other constructions rest on this principle.

Production of the synchronous action of two or more electric machines by allowing a fresh impulse to take place only when all the automatic contact-breakers are again closed, i. e., the armature movement of all the apparatus inserted in the circuit is completed.

Manufacture of insulated conductors for subterranean or submarine telegraphs by coating wires with gutta-percha.

Construction of machines which press the gutta percha without seam round the wires to be insulated.

Discovery of the phenomena of the charge in insulated subterranean or submarine conductors, and establishment of the law of the charge for open and closed circuits.

Establishment of the methods, measurements, and formulæ for determining the place of faulty conduction and insulation in subterranean circuits.

Through the admission of my memoir into the "*savants étrangers*," and another essay published the same year in Poggendorff's Annalen "On electrical lines and apparatus," which reproduced entire the contents of the memoir so far as they had reference to underground electrical lines, my priority in respect of various scientific and technical achievements has been placed beyond dispute. Nevertheless, unwarranted claims to certain of them were subsequently raised in divers quarters. This leads me to make here a few remarks on the need of an international literary tribunal, which has in recent times come to be felt with increasing acuteness. It must first of all be granted that in the course of the last decennia it has become ever more difficult, nay almost impossible, completely to survey the vast mass of material contained in scientific and technological publications, in many different languages moreover. It is also natural that those who are entirely absorbed in their own special work, but especially those who actively co-operate in furthering the development of the technical application of physical science, find but little leisure to make a thorough study of the doings of others working on the same or on related lines, even if masters of the several languages, and that they in general have also little inclination to turn their attention to the past. As an example of this I might point to the most highly gifted and copiously inventive physicist of any age, Faraday. He got to know the insulation with pressed gutta-percha only many years after its invention, when it began to be employed in England for submarine cables, the external protection of the insulated conductor being secured by surrounding the latter with iron wires. The surprising phenomena of electrical charges, which Faraday observed in these cables, induced him to publish an essay on the subject. When Du Bois-Reymond, however, sent him without further comment a copy of my memoir presented to the French Academy, Faraday did not lose any time in following up his first work with another, in which he cited the relevant sections of my treatise, and made the declaration that the priority both of the observation and also of the explanation of the phenomena belonged to me. Other English writers, as Wheatstone, Jenkin and many others, have certainly not troubled themselves about either this declaration of Faraday's or any of my other publications.

In Germany the good custom formerly prevailed of always prefacing the description of one's own scientific or technical discoveries and inventions by a description of the achievements of predecessors in the same department, thereby giving the progress about to be described its place in the historic evolution—a custom which unfortunately has never been observed in other countries with like conscientiousness. Hence it has hitherto been the peculiar glory of the Germans to recognize more than other nations the services of foreigners, and always to connect their own achievements with those of their precursors. This has been essentially facilitated by the knowledge, more diffused in Germany than in other countries, of foreign languages; but even apart from that, German science has always regarded it as a point of honor to practise literary justice equally towards natives and foreigners, and let us hope that this will be so also in future and that we shall thereby be spared the literary piracy which unhappily threatens to become prevalent even among ourselves.

(To be Continued.

An Electrical Fountain.

The various exhibitions which have been held during recent years have done much to stimulate electrical developments, especially on the artistic and spectacular side.

The electrical fountain is one of these productions and visitors to Paris and Chicago will recall the fascination that surrounded the extraordinary brilliancy produced by a combination of powerful streams of rising and falling water the main body of which was made to assume in rapid successions the varying tints of the rainbow, while the scattering drops and spray glistened and flashed like the dew in the morning sunshine. The continued development of electrical science and a constant demand for something new were united in the evolution of the electric fountain display at the World's Fair, which was one of the most attractive features in the electrical department.

Electrical Fountain, Lynn, Mass.

So attractive are these displays that corporations and private individuals have conceived the idea of beautifying public parks or private grounds by the erection of electric fountains upon them.

Lincoln Park, Chicago, has had for several years a most elaborate fountain of the kind, which is a never ending source of wonder and delight to the crowds who visit that favorite pleasure resort. Kansas City likewise was fortunate enough to secure one about a year ago.

A public spirited citizen of Lynn, Mass., now deceased, conceived the idea of bequeathing a sum of money to the City Council for the express purpose of erecting and maintaining such a fountain, and the accompanying illustration, with the following description, illustrates what has been attained and accomplished in carrying out the wish and intent of Mr. Wm. Shute.

The amount of the legacy, we believe, was something like $2,500, not an extravagant amount to be sure, but which, now that it has been judiciously expended, has produced something which may be considered "a thing of beauty," and therefore will be "a joy forever."

Some time ago the City Council advertised for bids from firms desirous of building and equipping this fountain on the Lynn Common. The award was finally made to the Franklin Electric Company, Kansas City, Mo., a corporation which makes a specialty of such work.

Mr. W. H. Blood, Jr., one of the principals in the Franklin Electric Company, took personal charge of the work, designed the entire structure and gave it his personal supervision until completed and accepted by the city of Lynn on Thursday evening, October 5.

In describing the fountain we may say that on Lynn Common there is what is known as the Frog Pond, in the centre of which the fountain has been erected. It consists of a circular wall built of field or cobble stones, some eleven feet high from base to parapet. The inside of the circle, which is about fourteen feet in diameter, is roofed over flat about four feet below the parapet, thus forming a submerged chamber about seven feet high and perfectly watertight. In this chamber have been installed all the apparatus requisite and necessary for producing the weird and beautiful effects that render it the most brilliant novelty in the East.

Looking at the structure from the edge of the pond there is no apparent entrance to the fountain except by climbing the wall, which forms a large bowl or miniature pond, in which, however, there is no water. In the floor of this bowl, which of course forms also the roof of the submerged chamber, is a trap door leading to the room below. There are also five circular windows in this roof, one in the centre and four equidistant around it, fitted with thick sheets of glass. Over these windows are water pipes, bent in circles and perforated with small holes through which the water is forced.

In the centre of each circle nozzles are fixed, the apparatus pointing upward. The central window has two circles of pipe, one within the other, in the centre being fixed a four-armed revolving arrangement for throwing a rotating twisting spray.

Beneath the windows are parabolic reflectors in each of which are fixed, not vertically as in the ordinary arc lamp, but horizontally, two carbons which form the arc lights, the rays from which shoot up through the windows into the rising and falling columns of water with an intensity that is fairly dazzling. By this means the water is simply illuminated, nothing more, and additional devices have to produce the changes of color which it is impossible to adequately describe. These changes are wrought out by an ingenious arrangement somewhat as follows: Between the upper flat open sides of the reflectors and the upper side of the circular windows, close under the roof of the chamber, are revolving frames containing six compartments filled in each with a different colored glass. These frames revolve horizontally on pivots by means of a sprocket chain connecting and moving them simultaneously. As the different colored glasses pass into the focus of the arc light the color of the water rising and falling outside is changed. This practically includes the whole electrical apparatus. The supply of water, however, is secured to the different circular pipes and groups of nozzles by a novel arrangement of pipes and valves that display much ingenuity in their installation. A big supply pipe coming up from the floor branches off into a number of smaller pipes, graduated in size like the pipes of a church organ, and each supplied with a valve.

Through one large pipe flows the water supply to the outer circle over the centre window; through another the water flows to the inner circle over the same window. A third pipe supplies water to the four outer circles; a fourth pipe to the central nozzle; a fifth to the central whirligig, and the last and smallest pipe of all to the four outer nozzles.

By the aid of these series of pipes and valves, and a plentiful supply of water, when the fountain is to be played, two men are enabled to produce the most brilliant effects. One man manipulates the valves while the other attends to the revolving colored glasses. Combinations and changes can be effected instantaneously.

As we have above stated, the fountain is the gift of a deceased citizen, and will be forever known as the Shute Fountain, that being the name of the donor.

After the work was completed, it was exhibited in operation by Mr. Blood on several evenings, to the intense delight and admiration of thousands of spectators. On the evening of Thursday, October 5, the fountain was finally exhibited before being accepted by the City Council. On that occasion there was a crowd of some 25,000 gathered on the Common, the Thomson-Houston Brass Band was in attendance, the entire City Council attended in a body, and at a given signal the water was turned on, current was switched in from the street circuit, and the light flashed forth in variegated tints.

Brief speeches were then made by prominent citizens, the designer and builder, Mr. W. H. Blood, Jr., receiving warm congratulations. An address to Mrs. Shute, wife of the donor, who was too ill to be present, was received with acclamation, and sent to her residence accompanying a handsome floral tribute. The Mayor accepted the fountain as a gift to the city, and with music, the playing fountain and general jubilation, the enthusiasm was kept up until a late hour.

A Foreign Notice of American Work.

BY ARTHUR SANKEY.

The comments of the London *Electrician* of December 1 on Lieutenant Patten's recently published description of "A System for Obtaining High Frequency Currents by Mechanical Means" should not be allowed to pass unnoticed. Judging from the lines quoted below it would seem the writer of them had not looked over the article he refers to in the New York *Electrical World* of November 18. He says:

"The device might have been useful for the production of very high frequency currents for theoretical purposes if it had turned out that the frequency was doubled at each additional armature, as in that case only a few armatures would have been needed to produce very rapid alternations, but, unfortunately, the frequency is only increased by a constant amount with each successive armature, and the chief value of the method for experimental purposes is found in cases where it is desired to know the exact frequency."

Those lines contain about as much misrepresentation of facts as could well be put into so many words, and though I am myself a Britisher, chance made me Lieut. Patten's assistant at his laboratory through all the course of experiments described in his beautiful series of "Laboratory Notes," published in the *Electrical World* of New York, and the experiments he describes are not fictions—they are facts.

If there is a feature of any value in his method of obtaining high frequency currents by mechanical means, it lies in the fact that the apparatus does precisely that which the London reviewer damns it for not doing, and such blunders in reviewing are only pardonable when done on purpose.

In the first column of Lieut. Patten's description of his multi-frequency experiments we find the following:

"Plainly in such a system the frequencies from one machine to the next *go on doubling*, as the series 2, 4, 8, 16, etc. Thus, if the first machine had twelve poles and made forty revolutions a second it would give 480 reversals a second, while the third would give four times this frequency or 1,920 a second."

Is there any ambiguity or haziness about that statement?

Quoting a few lines further on he says: "A practical speed for such machines gives 1,200 reversals at the first machine for the initial frequency—nearly 10,000 a second at the fourth, about 20,000 at the fifth, and the eleventh armature in series would give more than a million and a quarter reversals a second of absolutely uniform frequency." And this is what our critic refers to as the unfortunate and lamentable fact that the frequency is increased "only by a constant amount at each successive armature of such a machine," and were it not for this the machine might have been of some use for something. I would indeed like to know how a machine can be figured out to give a *constant increase* at each successive armature as stated by the *Electrician*.

Do Mr. Trouton's footsteps referred to show that? If they do I think Lieut. Patten would like to see them and follow them carefully as far as they go in that direction.

Now, here are some of the possibilities of the system described and put into operation at Lieut. Patten's laboratory:

Assume the machine spindle to revolve at fifty revolutions a second. Let there be twenty-four field poles for each armature, and let there be fourteen successive armatures secured to the common spindle. The first armature would evidently give 1,200 alternations per second and the successive armatures up to the fourteenth would give the following different frequencies: 2,400—4,800—9,600—19,200—38,400—76,800—153,600—307,200—614,400—1,228,800—2,457,600—4,915,200—9,830,400.

Thus you have quite a selection to choose from, that ranges from about 1,000 to 10,000,000 reversals a second. But that is not quite all the system is capable of giving, for suppose we vary the speed by 1 per cent., or 2 per cent., or 10 per cent., or any desired amount, then any one of these various higher frequencies will be increased or diminished by 1 per cent., or 2 per cent., or 10 per cent. of its respective value as above given. The system is thus not only capable of giving any frequency desired, but we are enabled to determine just what the frequency is, and hold any desired rate within very narrow limits of variation. The more complicated questions concerning the self-induction effects, capacity of condensers, etc., are out of place here, I simply contend that Lieut. Patten has invented and put into operation a system of obtaining high frequency currents by mechanical means by which he can obtain almost any desired frequency and know just what the frequency is and hold it nearly constant or vary it as desired, and I seriously doubt that there is any other way under the sun to do it.

A Miniature Electric Railway.

Among the novelties in electrical toys which are to be found in the holiday displays is an electric railway such as is shown in the following cut, which operates on a small battery current. The car trucks are 15 inches long, and the gauge of the wheels 3½ inches. The different styles of car bodies are made interchangeable, and may be used on any truck. The track is made of hard rolled brass and serves as a conductor for the current.

The motor is of the Premier No. 1 type built by M. R. Rodrigues, of Brooklyn, and is supplied with a pole changer so that the direction of the cars may be reversed. The motor is the single reduction type, the reduction being seven to one, and with half an ampere at six volts the motor car if loaded with two pounds will draw a trailer with a load of eight pounds and will ascend considerable grades with ease.

A Miniature Electric Railway.

At any point on the track a switch block, consisting of an angular block of wood, may be placed, which engages the lever of the pole changer and reverses the direction of the car automatically, so that by placing a switch at each end of a straight track the cars will run back and forth without attention. The track may also be laid either curved or circular at any radius above thirty inches. The truck is fitted up with springs and journals, and is substantially built to stand rough usage.

The complete outfit consists of one motor truck, three cars, the locomotive cab, passenger and freight cars, three cells of Premier No. 2 battery, 18 feet of track and necessary connections. A power house is provided at extra cost, which is used as a containing box for the batteries. These cells will run the cars for about thirty-five hours at a cost of fifty cents. Any of these parts are sold separately, and the outfit is easily set up and run by any intelligent child.

The price of the complete set is $25, and a motor truck and one car body $10. A locomotive with one battery which will make eight miles an hour and an electric launch are also about to be placed on the market.

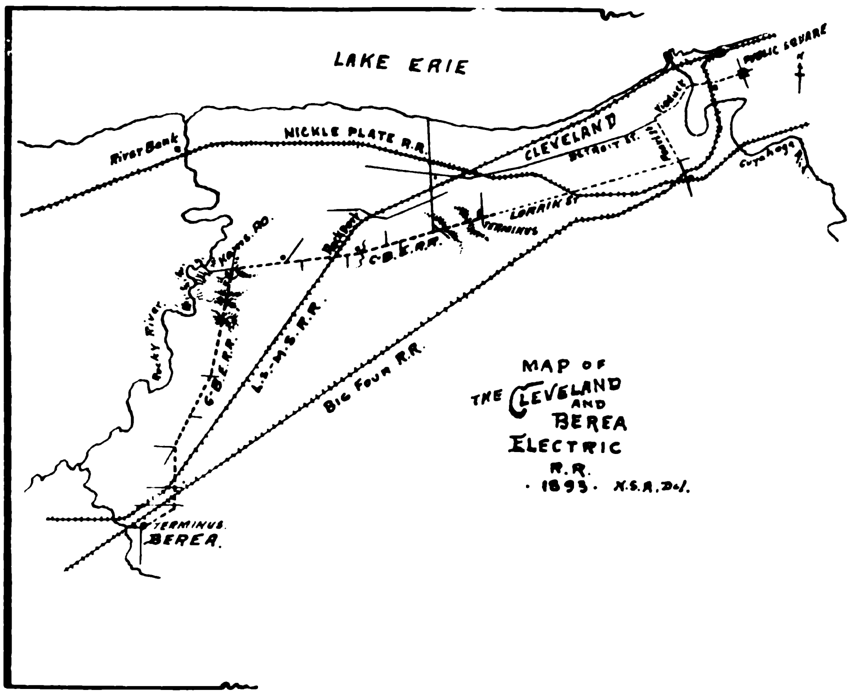
The Cleveland and Berea Electric Road.

This company has for some weeks operated its road with a storage battery car, of the Ford-Washburn type, with attendant success. The road is built of 60 pound rails, and extends along a public highway from the Henley street terminus of the Cleveland City Railway Company's Lorain street line to Berea, some ten miles distant. The roadbed has not yet been placed in the best condition, some of the curves needing easing up, and quite a material amount of ballasting is yet necessary. There are two grades of about 6 per cent. near the Cleveland end of the line, and at the Berea end there is quite a perceptible grade where the track passes beneath the Big Four railroad.

A number of the curves on the line are exceedingly sharp. Several bridges of considerable height are crossed, and a ride along this line is a rare treat. The scenery is quite varied; and from the fact that the section, through which the road passes is quite thickly populated for a country district, large patronage from this direction can reasonably be expected, as well as the larger patronage between the cities of Cleveland and Berea, where there is located quite a flourishing seat of education known as Baldwin University.

The road follows substantially the general direction outlined in the accompanying map, shown as Fig. 1. From this it will be seen that at Kam's post-office the road approaches near to Rocky River, whose precipitous banks upon either side make a ramble among the picturesque scenery which borders its sides a most delightful pleasure, and with this facility of transit open to the public, "a day in the country" is at once available to any one disposed to take advantage of it. This system certainly effects a large saving in the matter of equipment, since it is well known that the cost of overhead construction for a distance from eight to ten miles is a material obstacle, which undoubtedly stands in the way of many projects of this kind, for it is clearly obvious that the field of the trolley is confined to the shorter lengths of trips with a maximum number of car equipments, as against the field which seems to be difficult for the trolley to enter—viz., the long trips and a minimum number of cars.

So far but one car has been placed in operation, making six trips daily, three in each direction, leaving the Cleveland end at 8:30 A.M., 1:30 P. M. and 6:30 evening, and on the return trips leaving Berea at 6:30 A. M., 11:30 A. M. and 4:30 P. M.



The trip was made some days since by the writer, leaving the Lorain street terminus on schedule time at 1:30 P. M., in company with Mr. George A. Ford, president of the Ford-Washburn Store-Electro Company, and G. A. Washburn, inventor of the system and electrician of the company, and a complement of passengers.

Mr. Washburn was at the controlling stand, and manipulated in an expeditious manner all the successive movements of the car throughout the trip.

The car is equipped with 168 cells, and the controlling stand is provided with four successive positions which first divide the cells in four sets, placing them all in parallel; second, placing the cells in two sets and connecting them in parallel; third, placing them in series; and fourth, being the position when the cells are disconnected entirely. The first position gives 84 volts, the second 168, and the third 336. From this the following ammeter and voltmeter readings will be more intelligible:

The battery after being charged for about half an hour through a connection to the trolley wire, responded readily to the controlling lever, and the car quickly got under speed, to encounter within a few hundred yards the first grade of 5 per cent., which demanded an output from the battery of 90 amperes for a period of at least five minutes. The car, of course, did not travel at the speed it would if the controller had been placed in the third position. Ordinarily, on the level, the amperes required for the second position of the controller varied between 35 and 50, according to the condition of the track, while with the third position the ampere output ranged from 20 to 30.

Quite a large number of stops were made between Cleveland and Berea, the most in and about Rockport, where the line first crosses the Lake Shore and Michigan Southern Railroad, and the heaviest grades of the whole line had to be encountered in the outward trip. Near Berea the Lake Shore track is crossed a second time, and about a half mile nearer to the Berea terminus the track passes underneath the Big Four Railroad. At this point there is quite a grade on either side of the depression of the track.

The run was made in a little less than an hour, and the voltage of the cells as the car stopped within the temporary power house was 336, or two volts per cell.

Change of Name.

Prof. Wilbur M. Stine, director of the department of electricity at the Armour Institute, Chicago, in addition to his other duties, will have editorial charge of the monthly magazine, *Electrical Engineering*, and of the monthly summary of current technical literature, which heretofore has borne the title of *De Land's Synoptical Index*, but hereafter to be published under a separate cover bearing the title of *Electrical Literature*. Mr. Fred. De Land will retain the business management of both publications.

Trade Note.

The Interior Conduit and Insulation Company have recently sold Lundell motors, which are to be installed on the U. S. S. New York, now on the dry dock at the Brooklyn Yard.

ELECTRICITY

The Popular Electrical Journal.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES,	$2.50
IN CLUBS OF FIVE OR MORE,	$2.00
FOREIGN COUNTRIES,	$4.50
SINGLE COPIES,	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be eadily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not ater than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

Whom Does Patent Litigation Benefit?

If it is a fact, as reported, that Mr. Frederick P. Fish has handed in his resignation to the Board of Directors of the General Electric Company, there is only one sensible way to act upon it: it should be accepted by acclamation, not that Mr. Fish is either a dishonorable or an incompetent man, but because it is essential to the very life and existence of all the large manufacturing companies that ill advised patent litigation cease.

A direct saving of $25,000 a year in salary would be made by Mr. Fish's retirement, and this should be followed by the dismissal of every member of the legal staff except perhaps one or two to handle the routine matters of the office. If the General Electric Company had inaugurated this plan immediately upon its beginning business, the sales of the company would have been at least 25 per cent. larger, thousands of friends would have been saved to it, its suspended dividends could have been paid, and ELECTRICITY's campaign would not perhaps have been made.

Mr. Fish came into the electrical business fresh from his great successes in telephone litigation. He had proved himself a splendid lawyer, but like a great many others who have achieved fame at the bar, his head was so full of law that there was little room left for a clear understanding of the business situation.

He fell short of true greatness in that he was a lawyer only, and not a *wise and broad-minded counsellor*.

His perception of legal points was accurate, but he seems to have failed to see the difference in breadth and scope between the telephone business and the general electrical business. He failed utterly to realize that while the opposition in the establishment of the telephone monopoly had been fierce, the fight being won only after an exhausting contest, all the opposition in the telephone business was as nothing compared to what he had to meet in the electrical field.

In the telephone matter not over a half-dozen rival inventors appeared to offer serious contest to the claims of the Bell people; the art was little known and had tempted few workers; there was no established manufacturing business whatever in the opposition.

How different the situation in the electrical business. Here the fundamental principles of the art had been an open book for years; they had been taught in schools and colleges, and scores of able inventors had been at work, each contributing something towards the completion of successful systems for lighting and power; no one man had ever assumed to claim it all; manufacturing plants were scattered throughout the country, and millions of capital were invested. Those engaged in the business were neither thieves nor poachers; they believed they had a legal right to be in it, and their belief was backed up by the opinion of every man well informed in the history of the art that the moral and legal rights were not held by any one man or any one company or possible combination of companies.

Thus the opposition were not fighting for an idea; they were fighting for their vested property rights, and they were bound to fight like good Americans.

That they have done so Mr. Fish and his associates now know. Similar knowledge a few years ago would have saved millions of money to the companies which has now been scattered among lawyers, strikers and "experts," who have disgraced the whole system of expert testimony.

Under the pressure of the bitter and bloodthirsty competition which has prevailed, many deals have been made, collusive suits have been brought between two of the rivals, snap judgments procured, and so on to the nauseating end. But in each one of these cases the next turn of the wheel has changed the respective positions of the companies that joined hands for the nonce, leaving one or the other worse off than if no deal had been made. Collusive lawsuits, like chickens, always come home to roost.

All other litigation has been of minor importance to that over the incandescent lamp, and even a brief study of the lamp situation to-day should cause the stockholders in all the large companies to assert their rights, and demand that litigation be stopped. The lawyers have had their innings; the stockholders should now have theirs. Millions of money have been spent, valuable time wasted and splendid energies exhausted, to establish the fundamental Edison lamp patent.

What has it all amounted to? What electrical company is receiving one dollar of benefit?

After lawsuits without end, the legal fight is at best a draw, there is no monopoly in sight, and with only a few months more of life for their patent the owners themselves are compelled, in order to maintain an *even footing* in the business, to reduce the price of lamps to a point where profits are cut in two, a price which, if the owners of the patent sold *all the lamps during the next ten years*, would not reimburse them for the money spent in litigation.

And even now, after the public acknowledgment, by this reduction, that the *large profits*, which are generally held to be all there is worth fighting for in patent suits, are gone forever, lamp litigation still goes on apace. We have now awaiting decision the Buckeye case at Cleveland, where it is held the Edison patent has already expired; the Oconto case, the cases against the Novak people and De Khotinsky, and perhaps others.

With the *legal right* in this lamp patent we have not at present to do; the *moral right* was buried long since under tons of printed misstatements, perjured testimony and oratorical rot.

We repeat the question, Is it not time for the stockholders to take things into their own hands, throw overboard the lawyers, who are not *wise counsellors*, and who delight in showing their legal prowess, through long years of arguments and rearguments, while others foot the bills?

For several months the legal staff of the General Electric Company has been busy in preparation for numberless suits on the feeder patent.

One of these suits has been begun against the firm of contractors, E. G. Bernard & Company, who were about to install a plant at the Watervliet Arsenal, for which they had purchased Siemens & Halske apparatus. A preliminary injunction, based on the claim of intended infringement, was granted against the Bernard Company, and the hearing is set down for January 2.

Another suit has been brought against the Westinghouse and New York Insulated Wire companies for an alleged infringement on the World's Fair plant. We are not familiar with the plan pursued at the plant in question, but certain it is that even admitting the validity of the feeder patent (which we are not prepared to do) *no one needs to infringe it.* There are various ways of accomplishing the same object without doing so.

Feeder patent litigation has in it the possibilities of great annoyance, of an expenditure of large sums of money, of another rich harvest for the lawyers and venal experts, *but not one dollar of revenue* to the owners of the patent.

It is a matter of history that a short time before the consolidation of the Edison and Thomson-Houston interests a conference between these two companies and the Westinghouse Company was held to discuss this subject of patent litigation. A comparison of notes showed that all three had spent enough in lawsuits to pay full dividends for a number of years. It was agreed without discussion to discontinue the suicidal policy, and to compete on more sensible grounds. Not the least of the evils brought about by the combination referred to was the enforced nullification of this agreement or "understanding among gentlemen."

It is a fact which ought to have penetrated the heads of the stockholders long since, that the patents in this business worth fighting for are few in number, and that the revenue from a thoroughly established patent is not likely to return half the cost of litigation. The lamp patent more nearly approached the control of an essential feature than any other, and in this the results are plainly seen. Patents on minor details, once established, will be avoided and rendered of no avail by scores of the bright minds engaged in the business, who will accomplish the same object in other, often better, ways.

Patent suits so far have injured many and benefited none. If the trade is ever to be conducted on a profit earning basis, it will be after patents suits are dropped and the money and energy thus saved are directed to pushing the business in legitimate ways, perfecting the manufactured product and reducing its cost to the consumer.

A group of maniacs or savages standing on a narrow cliff might enter into a general struggle to see who would be the man to secure a monopoly of the position after the others had been hurled over the edge; civilized and sensible men, however, would prefer to go about their natural business.

We do not hold that patents should not be respected. They should be. More than this, they are respected, when properly used by their owners. It will be remembered that all the independent lamp makers stood in readiness a year ago to pay a royalty of ten cents per lamp to the owners of the Edison patent. Would it not have been a wise move to accept that proposition? Vast legal expenses would have been saved, and the patent would have been productive of a good income.

To properly appreciate the status of inventors, and owners of patents, it is only necessary to study the Constitution of the United States. There are not three interested parties — the Government, the people and the inventor—but only two, *the inventor* and *the people*, as the Government and the people are one.

The intention of the people in establishing the patent system was to stimulate inventions for the benefit of the people, with consequent benefit to the inventor. Patents handled in a business-like manner should be, and will be, recognized, respected and treated with proper consideration. Used as a club, to force something to which the inventor is not entitled, they are sure to meet with an unconquerable opposition—the opposition of right and justice.

……o……

Electrical Fire Risks. The question of fire risks from electrical sources is one that is constantly being agitated by different boards of fire underwriters throughout the country, and the prominence which has been attached to the subject has given rise to an exaggerated opinion on the danger of electric wires in the minds of the public. While a number of fires have been traced to electric wires, the proportion of these is very small compared with almost any other of the ordinary causes of fire, and in every instance the trouble can be traced to some defect of material or construction due to carelessness or cheap work. Every electrician feels confident that electric illumination is the safest possible method of lighting that has ever been devised, but this opinion will carry but little weight with the public as long as fires occur from this source, nor does the assertion that electrical wiring can be made absolutely safe make the risk any more desirable to the underwriters whose experience has been gained from several years' statistics.

In view of the fact, however, that in many cases the theoretical safety of electrical systems has not been demonstrated in practical operation, it is pertinent to inquire into the reasons for these failures, and to distinguish between any inherent defects in the system and the possible faults in the workmanship or materials employed. The electric light and electric railway wires are the only ones which in themselves present any great element of danger, and the telegraph and telephone circuits are merely considered as risks on account of their possible connection with the circuit carrying heavy currents. The multiplicity of overhead wires in many streets, to which may be added their often miserable and shiftless arrangement, has made this crossing between different circuits a too common occurrence, and besides the direct danger from fire this has frequently seriously handicapped the firemen in their work. This argues at once the necessity of first-class line work and the importance of high-class insulation; and although the most of the work put up at the present time is a great improvement over that of the past, there are hundreds of lines all over the country that testify to the ignorance and carelessness in regard to aerial lines a few years ago. Wherever such lines remain they involve a grave danger and will eventually, if not replaced, result in the demand to place all street lines underground.

The electrical companies in New York City were forced to make this change at a very great expense on account of the dangerous condition of the overhead lines, many of which had been abandoned. As a single bad line may cause trouble with every other line with which it may come into contact, it behooves every company to pay strict attention to its line work in order to avert the cost of underground construction, which will be likely to follow any succession of accidents.

It is within the reach of every city to bury all wires except the trolley lines, and now that the practicability of underground wires has been proved, and with that construction the companies are forced to maintain a high standard of insulation in order to operate, this method is likely to be demanded if any provocation exists. The poor work which remains from years ago will always remain a menace to safety as long as it is in existence, and until it is entirely weeded out electricity cannot attain the standard of safety which under proper conditions it deserves. The subject of interior wiring will be considered in the next number.

……o……

The patent litigation of the General Electric Company has been a series of blunders. The greatest blunder of all has been in attacking a plant in which the Siemens & Halske Company have a direct interest. A mine of information as to the history of the art has been dug into, and the utter confusion of the General Electric Company is inevitable.

Personal

Mr. Alex. H. Lewis, now representing the Curtis Electric Company in the West, was in town last week.

Messrs. James I. Ayer and H. P. Broughton, two gentlemen well known to most of our readers, have started in business as consulting engineers at St. Louis, under the firm name of Jas. I. Ayer & Company.

Mr. F. R. Chinnock, who has many years of successful work to his credit in the electrical field, has resigned the agency of the Ball Engine Company in New York, and will again be identified with the electrical business directly as representative of the Excelsior Electric Company.

Messrs. C. H. Angier & Company have succeeded Claflin & Kimball as agents for the Mather Electric Company in New England. Mr. Angier has had charge of the selling department of the Mather Electric Company. Mr. C. A. Bowditch will be at the head of the motor department of the new concern.

The Correspondence School of Messrs. E. P. Roberts & Company, in Cleveland, is in a flourishing condition, and has proved a thorough success.

What Judge Shipman Said as to Non-Infringing Lamps.

Considerable comment has been heard on the remarks made by Judge Shipman during the hearing in the Novak lamp case at Hartford in regard to the stopper lamp. The matter is of great importance, and the correct version is here printed for the first time, from the stenographic report taken by our Mr. W. S. Key :

" Judge Shipman said that in some of the cases which had been tried certain rebuttal evidence had been put in and accepted as being relevant to the case. In the Novak case, then under consideration, any rebuttal evidence would be of slight importance. This, however, applied only to infringing lamps; if a lamp that really did not infringe the Edison patents was brought into court, rebuttal evidence might not be admitted, and he (Judge Shipman) conceived of such a case coming up for settlement at some time, for there was a lamp that had been made for some time past, in fact was being made now and sold in quantities, that apparently did not infringe. It was known as a 'stopper lamp,' and was being made by the Westinghouse Electric Company. He had heard that lamp spoken of disparagingly by some as though it were a failure. Be that as it might, there was the fact that the Westinghouse Electric Company had introduced the stopper lamp as an economical, efficient and commercially valuable device; they contracted to light the whole of the World's Fair buildings with that lamp, and did so satisfactorily, and he had yet to learn that the Westinghouse Electric Company was any poorer as the result of introducing and using its stopper lamp."

A Boston View.

(*From the U. S. Investor.*)

The feeling existing between the two factions in the General Electric Company does not seem to be the pleasantest, and if it were in their power to do so, there can be no doubt that the old Thomson-Houston crowd would be glad to take measures to get their company back into their hands. It seems to be good opinion that. they would welcome the opportunity to bring suit for the annulment of the agreement on the ground of misrepresentation. We understand that it is claimed that after the consolidation it was found that the Edison Company came short about $1,000,000 of possessing the amount of assets credited to it before that event. In addition to this there was the enormous floating debt of the Edison Company, concerning which the Thomson-Houston people claim to have been in ignorance. The belief that these two companies will eventually be severed has gone so far that the policy of the Thomson-Houston, as a separate concern, is already being outlined. The company, it is said, will in the future lay itself out on the street railway business, paying little regard to the present lighting business of the General Electric. It is said, however, that Prof. Thomson has perfected a new incandescent light, which is superior to anything yet put on the market, and that he has assigned this to friends of the old Thomson-Houston Company outside of the General Electric.

There would be no necessity for outlining the policy of the Thomson-Houston Company under these circumstances. This company has always followed the golden rule in its treatment of competitors and licensees, " Whatsoever ye would that men should do to you, do ye even so to them." Of course it would not at this late day deviate from the policy which has made it beloved by all.

National Electric Light Association.

At a meeting of the Committee on Arrangements, held in Washington on the 19th inst., the Ebbitt House was selected as the headquarters of the Association for the Convention in February.

The meetings will be held in Grand Army Hall, 1412 Pennsylvania Avenue, within one block of the hotel.

The Electrical Transmission of Power from Niagara Falls.—IV.

BY PROF. GEO. FORBES.*

GENERAL DESCRIPTION OF A 5,000 H. P. ALTERNATOR.

On the bed-plate a vertical cylinder is bolted, with projections to support the fixed armature and the bearings of the revolving part. The armature coils are wound independently and can be removed and changed. They are fixed in slots in the fixed armature. They are encased in an oil-tight casing through which oil can be circulated. The field magnet is external to the armature, and has the poles pointing radially inwards.

It consists preferably of forged steel supported by a spider with eight arms, which may be of steel with a covering of thin sheet metal, on which cups are provided for forcing air into the interior of the machine. The pole-pieces are bolted on to the steel rim. The field coils are of copper strip, two coils being wound upon each pole, with a space between them for air circulation. The exciting current is applied by rings of tempered copper on the spider, having fixed brushes rubbing on them. The hub of the spider is firmly fixed to the upper end of the shaft. The spider supports the heavy rim by 16 studs and nuts. The shaft is supported by two bearings, each of which has four radial arms, which are bolted to four corresponding projections on the cast-iron cylinder. This cast-iron cylinder is bolted to the bed-plate and adjusted thereon by wedges. Besides having on it the projections for carrying the bearings on its inner side, it has on its outer periphery a series of vertical ribs against which the stampings, or sheets of iron forming the armature, rest. It also supports the lower end plate on which the armature is built up, and the armature is keyed to it by a single key. The armature is wound drum fashion—that is, all on the outside. This enables the coils to be wound independently and laid in their place, and also to be easily replaced in case of accident. In order to do this satisfactorily, the slots for each coil in the iron are cut, not radially, but parallel to each other. Each coil is encased in insulating material, which forms a tube through which oil may flow as in a transformer, but may be forced, in which case its circulation is maintained by a pump. Round the base of the machine there are two oil pipes, one being the inlet, the other the outlet. The inlet pipe is connected with a reservoir of oil in the power-house. The outlet pipe leads by another pipe to cooling arrangements in running water, from which the oil is pumped to the reservoir. From the inlet pipe 16 brass tubes are led to the junction boxes at the bottom of the 16 coils; the 16 other brass tubes are led from the junction boxes at the top of the coils through the interior of the fixed armature and bent over the foundation plate, and so connected to the outlet pipe which surrounds the bed-plate. The bed-plate is a single iron casting, and in order to enable it to be transported over the railways it was necessary to limit its diameter, as shown in a supplementary drawing, which shows the improved oiling arrangements, which were worked out by my chief draughtsman at Niagara Falls, Mr. Baumann. The armature is built up of thin sheet iron, with ventilating spaces, as shown on the drawings. The bolts which hold the armature together are eight in number, to be made of nickel steel, a metal which has the great advantage of being non-magnetic and of very high electrical resistance and great mechanical strength. The amount of nickel is 25 per cent.

There are 16 armature coils, eight being of one kind, called "short" coils, and eight of another kind, called "long" coils, the length of wire on each coil being the same. The short coils are bent over at the end plate, and the long coils are wound in one plane and enclose the short coils. I find that if we are to have a very stiff field, with first-class quality of iron in the fields, each coil would consist of 72 turns of pure copper wire No. 0 of the Brown and Sharpe gauge, which gives a very low density of current, and reduces the heating. In fact, it has been my view that in designing the machines for so great and permanent a work every effort should be made to reduce the rise in temperature, even to far below what has ever been done in the past. The unequal expansions and contractions of materials in a machine of this kind are very injurious to its permanence, and affect the insulating material seriously. The layers of wire in the coils are separated by mica. Each coil when wound has strips of insulating material laid spirally round it, so that oil may circulate freely in the intervals, and the whole is encased in a casing of strong insulating material. The material which I prefer for this purpose is certainly woodite, an eighth of an inch of which will not break down with 30,000 volts, and which is not acted upon by oil even at high temperatures. I have a record of tests with oil which are conclusive on this point. It is quite the best material I have seen for the purpose, though costly, and, being a secret process, it may be difficult to ensure uniformity.

The frames of the bearings are of cast iron, with four radial arms, which rest upon four projections cast on the vertical cylinder, and are bolted to them. By this means, when the field magnet with the shaft have been lifted out of place, the bearings can be twisted through an angle of 45 degrees in a horizontal plane and then raised out of place, leaving a space of five feet in diameter through which portions of the turbine shaft can be raised for repair. The bearings are oiled at the centre by oil forced under pressure through a pipe. The oil is then distributed over the bearings by spiral grooves. A spiral groove is also cut in the hub of the frame, with a pipe at each end to admit of water circulation to cool the bushing. At two opposite sides of each bearing the bushing is made thin, and a rod of bismuth is soldered thereto; so that if the bushing is heated a thermo-electric current shall be created which, by means of a relay, can ring a bell in the power house. When this occurs, water can be immediately admitted to cool the bearings, and the attention of the workmen is drawn to the necessity of an examination.

One of the parts which required most consideration was the material of which the spider supporting the field magnets should be constructed. The best plan is to make it of steel, for the sake of lightness, and to cover it with a copper covering, which might, I think, be spun; or perhaps better, electro-deposited nickel might be used.

Between the pole-pieces the space is filled up with a screen or plate of metal so as to direct the air ventilation only upon the parts which most require cooling.

The methods finally selected for oil circulation are shown in a separate drawing.

It will be obvious from this design, considering that the speed of revolution is 250 per minute, that great care has to be devoted to the balancing of the revolving parts; everything has to be calculated not only for a speed of 250 revolutions, but for double that amount, which is the maximum speed at which the turbines could possibly run—at which speed they might run through a breakdown of the governor, although this is an accident almost impossible to occur. Each of the revolving parts will of course be balanced individually, and I have suggested a plan for the final balancing which seems likely to be effective.

---

* From a paper read before the Institution of Electrical Engineers, England.

A temporary bushing would be put in the bearings, of india-rubber lined by a thin metal tube. The dynamo would then be rotated slowly and the balance adjusted in the usual way. The speed of revolution would be gradually increased—a new adjustment being made at each speed—until a speed of 500 revolutions a minute is attained, and when an adjustment has been made at this speed it is pretty sure that the balance at 250 revolutions per minute will be very perfect, and the mechanical friction reduced to a minimum.

As stated before, the oiling arrangements have been introduced not only to ensure higher insulation and to preserve the insulating material, but also to lower the temperature as much as is possible, because every step we take in the reduction of temperature is an advance. These oiling arrangements may perhaps be adopted in the future, but at present we are not making use of them in the machines which are in process of construction. When we have had experience with these we may in future adopt the oiling arrangements; and as there is likely to be a great development in the direction of electric transmission of power in connection with the utilization of water power in many parts of the world, it has seemed well to me to put before you these details, so that they may be considered in other cases that may arise.

At a meeting of the board of directors in New York lately it was resolved, on the recommendation of the consulting engineers of the company, that the contract for two or three alternators, each of 5,000 H. P., should be assigned to the Westinghouse Electric and Manufacturing Company, of Pittsburg. I would wish to state how much we owe to Mr. Westinghouse, and to his chief engineer, Mr. Schmid, for the zeal with which they have taken this matter up, and their desire to meet our views and to secure for us machines of which they felt they could guarantee the satisfactory performance.

Before leaving the subject of the dynamo, I would wish to point out that it has been designed for special circumstances in connection with the Cataract Construction Company's work. If a dynamo of the same type were being constructed for another place, it is certain that modifications would have to be introduced. I particularly draw attention to the fact that some trouble in getting out a good mechanical design arose from the necessity which existed of being able to provide a clear space of about 5 ft. diameter in the middle of the machine without taking the whole machine to pieces, the object of this being to enable us to lift up portions of the turbine shaft which it might be required to put into repair. In any case, where the long shaft existing in our case is not required, the design of the dynamo is much simplified and would more nearly approximate to the first design, of which a drawing is shown, but arrranged for 33 periods a second.

If the present Paper were intended to relate solely to the subject of utilization of power at Niagara Falls, I would be content with describing what has actually been done: but I foresee that there is going to be a great development in utilization of water-power and its electrical transmission. I am therefore inclined to say a few words on some other details which we have been carefully considering, but about which no definite decision has been arrived at.

Before doing this I would direct your attention to the drawing representing a plan of our power-house, in which you will preceive the inlet passages, A, from the great canal, B, which draws its supply of water from the upper river. From these inlet passages the iron pipes, or flumes, C, pass vertically downwards to the bottom of the great wheel-pit, which is a slot cut in the ground to a depth of nearly 200 ft., at present large enough to contain four turbines in line, but which can be extended to a much greater length, the whole capacity of our tunnel being 100,000 H. P. The drawing shows circles, D, in the plan, which indicate the position of the turbine and dynamo above it, and the position of a hatchway, F, by which material can be raised or lowered. It will be noticed that between the inlet channels and the wheel-pit the flumes are bent downwards, and thus leave a V shaped space, G, which I have appropriated to make a subway, running along the whole length of the power-house, to carry the high-pressure conductors. It will of course be understood that the slot forming the wheel-pit is arched over at the top to form the floor of the power-house, upon which the dynamos rest. It will be noticed that at the north end of the power-house there is a large square chamber, H, in which I propose that all the measuring instruments and other apparatus under the control of the chief electrician shall be assembled. Underneath this chamber there is a cellar in direct communication, first, with the subway which I have described as existing in the power-house; and, second, with the subway which leads outwards from the power-house at present as far as the Pittsburg Reduction Company's works, and may possibly eventually lead to Buffalo. In the cellar all the high pressure wires, the transformers, the artificial load and other high pressure machinery will be placed. It will be noticed that other spaces are left in the floor forming trenches along which the conductors can be carried. With these arrangements there can be no possibility of danger to any person in the power-house; and if any wires are to be found laid along the walls of the power-house or elsewhere, I wish it to be a maxim that we shall be able to place upon these wires a card marked "No Danger," so that there will be no possibility of any danger from any person touching anything in the power-house.

With regard to the exciting current, the best plan available at this moment is to use one of the machines which are generally known as the Schuckert machines for converting the alternating into a continuous current, transformers being inserted in order to lower the pressure. In order that the exciting current may increase with the load, it would be well to make these transformers of special construction, each having two primaries and one secondary. One of the primary coils would be in series with the main circuit, and the other in shunt. I would furthermore make these transformers sufficiently large to deal with all the dynamos which are in the central station, and I would subdivide the secondary coil into sections, to enable us to cut out a section of the transformer when we cut out one of the dynamos. When we wish to cut out a dynamo, a switch would be worked which would at the same time short-circuit the field coils of that dynamo and also cut out one section of the secondary of the transformer which is supplying the exciting current to all the dynamos. This plan allows the fields of all the alternators to be put in series—a desirable arrangement for parallel working. A resistance may, of course, be put in circuit with the fields of the alternators for regulation.

I presume it will be taken for granted that in any large work of this sort the primary circuit should never be broken when in action. For my part, I hold that this should be the case even in smaller stations.

An important feature for putting the dynamos in parallel, and for removing a dynamo, is an artificial load. It is desirable that this artificial load should consist partly of a resistance and partly of self-induction. It is only by this means that the dynamo which is going to be put in circuit can be brought to exactly the same conditions as those which are working, both as regards volts and amperes. It may be well to describe the operations which take place when a dynamo is switched in parallel with the others. First, connection is made between the armature and the artificial load; then the exciting switch is turned so that an extra section of the transformer is put into play, and the short circuit on the field coils of the dynamo is broken. The dynamo being excited, the turbine is then started, or this may be done at first. The artificial load is then adjusted until the dynamo is giving the same volts and amperes as the others. A synchronizer is then placed between the artificial load and the external circuit, and so soon as the synchronism is attained a switch is closed which connects the artificial load with the external circuit. Resistance is then put into the artificial load until there is very little current going through it, when it is switched out, and the dynamos are all working in parallel. To cut out a dynamo from the circuit the operations are performed in the opposite order. The artificial load with high resistance is put in connection with the external circuit; this resistance is gradually diminished until it indicates the amount of work that is being performed by one dynamo; the connection between the artificial load and the main circuit is then broken, leaving the dynamo (which is being switched out) feeding the artificial load. The resistance of the latter may then be increased, and the exciting switch actuated so as to short-circuit the fields of the dynamo, and to remove one section from the secondary of the exciting transformer. The supply of water to the turbine may then be shut off.

If machinery is worked, even at 20,000 volts, in the manner I have described, there is no possibility of injury from any great rise of electrical pressure, unless the external circuit be by any means accidentally broken. To provide against this sort of trouble I would have wires coming from the external circuit where it enters the power-house, connected through a large resistance, or through the primary of a transformer the secondary of which contains a resistance. In circuits with it I would have a break consisting of two carbon points at a distance of about half an inch apart if we were dealing with 20,000 volts, so that an arc could not be formed unless the pressure rose above the normal value. Under these circumstances, so soon as any resonant effect due to the breaking of the circuit or due to any other cause raises the electric pressure above the normal, an arc is established across the carbon points, and so a load is put on which removes the cause of the extra high pressure. This is the only automatic means which I have been hitherto able to think of which is sufficiently rapid in its action to overcome any possibility of injury to the dynamo or transformers.

I have attempted in the course of this paper to give you some idea of the work which has been actually done or decided upon at Niagara Falls, and also to show you the views to which I have been led by any special experiences which I may have had as to the general ideas which ought to guide us in the construction of the plant in the future for transmitting power to a distance electrically.

In describing the different plans which are available I have avoided mentioning the names of those numerous electrical engineers and manufacturers who, by their inventions, researches or applications have advanced the art; or discussing their claims to priority; but I cannot conclude this paper without mentioning the names of some of those who, in one way or another, have made great steps in the applications of alternating currents to power purposes. I would particularly mention the names of Messrs. Ganz & Company, Mr. Schuckert, the Allgemeine Electricitäts Gesellschaft (of Berlin), the Oerlikon Fabrik and Messrs. Brown, Boveri & Company; also Mr. Eickemeyer, Mr. Ferranti, Prof. Ferraris, Prof. Fleming, Dr. J. Hopkinson, Messrs. Hutin and Leblanc, Mr. Rankin Kennedy, Prof. Mengarini, Mr. Mordey, Mr. Tesla, Prof. Elihu Thomson and Mr. Henry Wilde. I feel that all of us owe a great deal to their work.

In conclusion, I wish to draw attention to the figures which show the relative merits of high and low frequency with polyphase motors.

Everything is identical in the two figures except that the frequency of one (a) being double of the other (b); a has 16 poles, b has 8. The armature is identical in both, and revolves at the same speed and does the same work; and the field revolves at the same rate in both, and the induction and current-density are the same. The differences are that a has more copper and less iron than b. The comparison of efficiency depends on the depths of both. As an example, assume that a has 50 per cent. more copper in the fields than b, the ampere turns per pole being necessarily the same in both, and that b has 50 per cent. more iron than a, and that the hysteresis loss in b ($= H_b$) is equal to the resistance loss in its copper coils ($= C_b$). The values for a are:

$$H_a = 2 \times \frac{2}{3} \times H_b;$$

$$C_a = \frac{3}{2} C_b;$$

$$H_a + C_a = \left(\frac{4}{3} + \frac{3}{2}\right) \frac{H_b + C_b}{2}$$
$$= 1{\cdot}42 \times (H_b + C_b).$$

Thus the total losses in the field of higher frequency (neglecting eddy-currents) are 42 per cent. more than in the field of lower frequency.

(*Concluded.*)

SOCIETY NEWS.

Franklin Institute Lecture.

Prof. Elihu Thomson delivered a lecture Tuesday evening, December 19, before the Electrical Section of the Franklin Institute, upon "Cosmical Electricity." He presented several speculations concerning the earth, solar system and other bodies in regard to their electrical relations with each other, and whether the earth is electrified and undergoes various changes of electrical conditions. By means of some apparatus he defined and illustrated electrostatic capacity, potential, the relations existing between electrified bodies, etc. Although there is a difference of opinion regarding the question, "Can a true gas carry or retain a charge of electricity?" he regarded it in a negative sense from some personal experiments. Thus the dense atmosphere quite near the earth indicates only a very low potential. However, it is well known, he said, that as we ascend we come into layers of air more rarefied and in a different electrical state from our own atmosphere, for instance, the top of Washington Monument—550 feet, shows a potential of 3,000 to 5,000 volts, Eiffel Tower, 1,000 feet, about 10,000 volts potential, and if the same increases as we continue to ascend, it should be about 1,000,000 volts 20 miles up.

From this reasoning, he speculated that the earth was electrically charged like a high condenser with negative electricity, and the upper layers of air highly positively charged with respect to the earth, the dense atmosphere acting as the dielectric. Thunderstorms might be produced by a flow in the dielectric, that is, a portion of the air more rarefied than the rest, which would give an opportunity for potentials to even up and a redistribution to take place. After stating that the potential on a charged body would be greatly increased by the contraction of the body, which of course lessens the capacity by decreasing the surface, he supposes the sun to be electrically charged, the noted disturbances, etc., occurring every eleven years, due to the fact that the contraction of its surface raised the potential enormously, and that a discharge was necessary for an equalization. After the discharge, it took the next period for a like amount to accumulate. The discharge would be conducted outwards by the coronal lines at the time of an eclipse, and so powerfully that after reaching our earth there comes an equalization of potential with accompanying meteorological effects.

Comets, which are rarefied gaseous bodies, might be similarly charged, and coming into contact with one of these rays from the sun, would be luminously affected by a redistribution of its potential. Thus they would be visible to us while passing through the ray only.

Temporary stars might be accounted for in a like manner, and it is quite probable they shine, like brilliant arc lights, during the time they traverse such an electrified medium, and afterwards disappear entirely from our view.

The subject was most interesting and entertaining, even if it was quite speculative and not dignified enough, as the Professor said, to be called theory.

COMMUNICATIONS.

The Vulcanized Fibre Company.

To the Editor of ELECTRICITY.

DEAR SIR: In your issue of December 13 you say editorially: "It would be interesting to know just how much stock in the Vulcanized Fibre Company of Wilmington, Del., is held by Mr. F. H. Webster, the purchasing agent of the General Electric Company, and just how and for what considerations Mr. Webster obtained the same."

As I am in position to answer that question officially, and from my own positive knowledge, I desire to say that neither Mr. Webster nor any other officer, director, agent, or employe of the General Electric Company, or any of its branches, ever held or owned a share of stock in Vulcanized Fibre Company, either directly or indirectly, nor have any of them ever been interested in any way, directly or indirectly, in the business or profits of said company, or received any commission, fee, gratuity, reward, or even social entertainment, from said company or any of its officers or employes. Nor has this company had any oral or written communication with Mr. Webster for the past fourteen months.

Respectfully yours,
WILLIAM COURTENAY, President.
New York, December 22, 1893.

[The above statement from Mr. Courtenay is accepted by us as correct as to all matters to which his knowledge extends, and we regret having done an apparent injustice. In regard to the inner workings of the purchasing agency of the General Electric Company we may have something further to say.—ED.]

Electrical Words, Terms and Phrases.

Desiring to find the definition of the phrase "Johnny, go get your gun, shoot!" which I noticed was used in an electrical journal, I bought an electrical dictionary and looked it up with the following result:

I naturally first looked under "J," where I found "Johnny, shoot, gun, get, your, go, —— ——. (*See* Get, gun, Johnny, go, shoot your ——)." Under this heading I was referred to: "*See* Gun, your, Johnny, go get shot." Under this I was further referred to: "*See* Go Johnny, shoot, your gun," and upon looking this up I was referred back again to "Johnny," where I had started my search. I was told by the author that it was in his dictionary but he did not remember where. Not wishing to go through this cycle again, and being determined to find it, I began at A and read over the whole dictionary, being rewarded at finding *near the end*, under Y, (!) the following: "Your, go get gun, shoot Johnny. —— —— A phrase proposed to signify that Johnny should get his gun before shooting it."

My curiosity as to why this phrase was in an *electrical* dictionary was satisfied when I read on and found the following: "It might be used in electrical writings in case the gun was electrical or Johnny an electrician. It would seem that a more polite phrase would be preferable."

I presume it was my fault for not looking under "Y," but perhaps you can give me and your other readers a general rule to go by which avoids having to read over the whole dictionary.

New York, Dec. 22. AMATEUR.

Boston Notes.

The Union Traction Company of New York and New Jersey have for some time past been figuring on a plan for purchasing the entire system known as the Interstate Electric Street Railway, which joins the States of Massachusetts and Rhode Island, passing through the towns of Attleboro, Wrentham and the cities of Pawtucket and Providence. The purchase has not yet been quite consummated, but is likely to be, and this fact is stirring up the local capitalists a good deal, for many of them are opposed to the sale of the system, believing that such a change would be detrimental to the interests of some of the towns in the district, hence they are having the whole matter carefully examined into by two experts with a view to securing it against being transferred to foreign capitalists.

The Eastern Electric Cable Company has just declared its regular semi-annual dividend of 3 per cent., payable January 1, 1894.

The Christmas decorations in the large dry goods, furniture, jewelry and other stores in Boston are in many respects more attractive than in any former year. Certainly they are much more brilliant than ever, owing to the liberal use of electricity. For both exterior and interior decorations nothing has ever been seen like it. The most weird, uncanny, as well as the most artistic, effects are to be seen here and there, with the result that several of our principal streets are absolutely impassable in the evenings by reason of the wondering and admiring crowds which are everywhere.

With few exceptions the various electrical supply houses and manufacturing firms in Boston are again busy, and feeling themselves in something like their old-time form. Only let the politicians—one had nearly written statesmen—at Washington, define the extent of their tariff reform labors, and the electric business will once more boom.

The rumors which have been rife for several weeks past in and around Boston and Lynn, to the effect that the works of the General Electric Company were to be removed from Lynn to Schenectady, have created quite a stir and commotion. Of course the reports are denied by officials at the works, nevertheless there seems good reason for believing there is some truth in the rumors. Mr. E. Wilbur Rice, Jr., superintendent of the works, is emphatic in denying these rumors as having no foundation. When asked a day or two ago what was the outlook for business at Lynn, his reply was: "I do not know how much business we may do, but our condition will in all probability be like that of the rest of the country; if business is good generally it will be so with us; if, on the contrary, the depression exists for any length of time, we shall, like other concerns, continue to feel the effects of it." Asked about the rumors that the predominant interest in the General Electric Company was opposed to the works remaining in Lynn, Mr. Rice said: "That is pure rot. Our factories are, of course, run in the interest of the corporation, and not for the purpose of benefiting any particular section; but it is a fact that we are getting even more than our share of the work, and rumors to the contrary are utterly false and misleading. The present condition of affairs at Schenectady is, if anything, worse than that here, and I have no doubt whatever that when business revives on a healthy basis we shall get our full share of it." True, Oh King! we shall see what we shall see.

General News.

What is Going on in the Electrical World.

Houston, Tex.—This city has now over fifty miles of electric car lines, comprising twelve different routes.

Worcester, Mass.—The plant of the Leicester Electric Light Company was damaged by fire on the 19th to the extent of $5,000.

Huntington, L. I.—An electric railway from Huntington to Oyster Bay by way of Cold Spring Harbor is projected. The distance is about eight miles.

Westfield, N. J.—A route has been surveyed for an electric railway from Westfield to Millburn. Work will begin on construction early in the spring.

Charlottesville, Va.—D. Harmon, attorney of an incorporated company, has applied to the council for a franchise for an electric street railway in this city.

Columbia, S. C.—The Columbia Street Electric Railway and Power Company have petitioned the council for permission to extend the railway on several streets.

Gloversville, N. Y.—The Gloversville Street Railway Company and the Cayadutta Electric Railroad Company have been consolidated, with a joint capital stock of $350,000.

Cohoes, N. Y.—The contract for putting in the new fire alarm system has been awarded to the Gamewell Fire Alarm Telegraph Company, which agrees to do the work for $6,300.

Jamestown, N. Y.—A fly wheel making 250 revolutions a minute burst on the 15th inst. at the electric light station, doing considerable damage to the plant but injuring no employees.

Elwood, Ind.—A meeting has been held here in which favorable consideration was given to the projected electric railway to Alexandria, and thence to Franklin, a distance of eighteen miles.

Auburn, N. Y.—The Electric Light Company have had a large force of men at work preparing the lines for the prompt fulfilment of their contract for lighting the streets, beginning next month.

New Brighton, N. Y.—The Electric Power Company has come to an agreement with the village trustees and will receive the old price for arc and incandescent lights for the year ending April next.

Geneseo, N. Y.—The people of this village are yearning for electric lights, and are about wrought up to the point of demanding from their hesitating officials the necessary action to obtain them.

Tamaqua, Pa.—The Citizens' Gas Company of this place have sold their plant to Philadelphia capitalists, who will take possession on January 1 and greatly enlarge it and add arc and incandescent electric lighting.

Little Rock, Ark.—The contract for the erection of the new electric lighting plant has been secured by the Fort Wayne Electric Company, the consideration being $26,650. Including the building the total cost of the plant will be $29,875.

Rutland, Vt.—The Marble City Electric Company are hurrying the work on the lines laid out by the Committee on Lights. A large number of men have been employed in erecting poles and making the foundation for the new electric light station.

Geneva, N. Y.—It is reported that plans have been made here for putting on Seneca Lake an electric boat for commercial purposes. The boat is to be 150 feet long, 25 feet wide and 9 feet deep, with 5 feet draught. It will be driven by twin screws.

New Britain, Conn.—The contract for street lighting now held by the Central Railway and Electric Company will expire on the 1st of January. The present contract price is $91 per year each for 96 electric lights, and it is thought the existing service will be continued.

Toronto, Can.—The Reliance Electric Manufacturing Company have petitioned for a franchise for lighting in the section of the city west of the subway. It is the purpose of the company to begin with a small circuit, and gradually extend their wires and business until they will compete with existing companies both in arc and incandescent lighting as well as supplying power.

Terre Haute, Ind.—A. R. Markle, electrician, has purchased the first incandescent light plant introduced in Indiana, and has removed it from the old Hutman building where it was installed. It was brought here in the summer of 1880 at a cost nearly four times as much as the same plant could be purchased for now. The old plant is about as good as when first placed in the building.

Falls Church, Va.—At a meeting of the citizens held on the 18th inst. a resolution was passed asking the council to submit to the freeholders the question as to whether or not they should bond the town of Falls Church for the sum of $10,000, said sum to be paid to the first electric railroad company that would build a road from Falls Church to Washington.

Hagerstown, Md.—The South Mountain Electric Railway, Light and Power Company, which is constructing a railway between Boonsboro and Keedysville, has filed here for record a mortgage executed in favor of the Baltimore Trust and Guarantee Company to secure an issue of bonds to the extent of $100,000.

Manchester, N. H.—At the last regular monthly meeting of the Board of Trade, the following members were appointed a committee to confer with the Haverhill Board on the subject of the proposed electric road: H. D. Upton, Frank W. Fitts, William Corey, Arthur S. Campbell, F. T. Dunlap and Secretary Eastman.

Long Island City, N. Y.—A new corporation has purchased the system of street railways owned and operated hitherto by the Steinway Railroad Company, and will use the trolley on the three routes composing it. Mr. Steinway retains a large interest in the new company, whose directors are Messrs. Babcock, McCabe, Peabody, Pruyn, William Steinway, Cord Meyer, John R. Lamson, Thomas W. Olcott and Eugene S. Bushe.

Syracuse, N. Y.—The Syracuse Heat and Power Company have applied to the common council for permission to use the streets and public places of the city so far as may be necessary for the construction and operation of a suitable plant for generating and furnishing electricity, electric light and electric power. The application is meeting with vigorous opposition from the old electric light company.

Cleveland, Ohio.—To secure an issue of bonds the Cleveland General Electric Company filed a duplicate chattel and real estate mortgage last week with the county recorder. The mortgages represented a loan of $1,000,000 and were drawn in favor of the New York Guaranty and Indemnity Company.—The announcement is made that the Walker Manufacturing Company is to change its cable machinery plant to an electric street railway machinery plant.

Pottstown, Pa.—It is understood that the contract for the construction of that part of the Pottstown, Boyertown and Reading Railway Company's electric road between this city and Boyertown has been let. The officers of the company are: President, James B. Craighead, Philadelphia; secretary, Mahlon G. Taylor, Pottstown; directors, James B. Craighead, J. M. Zook, Philadelphia; Charles K. Spatz, Boyertown; Mahlon G. Taylor, Pottstown.

Middletown, Conn.—The Middletown Electric Road Company will equip with electricity and extend its tracks next spring to Meriden and neighboring suburban villages. When the bridge to Portland is constructed the tracks will be laid across to Portland up along the river, meeting the Glastonbury road. Another winter will see a network of electric roads connecting Hartford, New Britain, Meriden, Middletown, Portland and Glastonbury.

St. Louis, Mo.—Assistant Chief Emile Gross, of the Fire Department, holds the opinion that the present apparatus used in putting out fires is too heavy and cumbersome, and thinks that electricity might do the work in a better way. He says: "I'd have wires come up at every fire plug. . . . A few small power plants scattered about the city would give a continuous current. We would have engines costing not one-half what present engines cost and weighing not one-third. A wire on them would connect with the wire at the plug. The minute the hose was ready the power would be turned on. No coal wagons—no fireman. Economy all around. One horse could take an electric fire engine to a fire."

Sioux City, Iowa.—A company has been organized here by John Pierce, A. E. Pierce, Peter Moller, Chris. Moller and H. A. Johns, to be known as the Consolidated Company. It has absorbed the Sioux City Cable Railway and expects to consolidate all the street railway systems in the city, namely, the Sioux City Street Railway, the Rapid Transit lines, Riverside Electric and Sioux City and Leeds Electric, into one electric system with forty-five miles of line. The company is capitalized at $1,000,000, with offices in New York and Sioux City. The incorporators have deeded property valued at $1,200,000 to the company, consisting largely of desirable real estate.

Philadelphia.—The Electric Traction Company have been experimenting with the storage battery system, and have reached the conclusion that it cannot be utilized on any of their lines. —The *Times* of the 19th says: "The immense value of the trolley system as a money-earner and dividend-maker have been more than demonstrated by the brief experience of the Traction Company's Thirteenth and Fifteenth Streets Line. President Widener stated yesterday that in the two days in which the trolley has been in operation—Saturday and Sunday—the earnings of the line have increased no less than $2,200 and that without any increase whatever in the expenses, making a clear gain of $1,100 per day." —The Philadelphia Traction Company has awarded the contract for the engines and generators necessary to fully equip the central power plant, at Thirteenth and Mt. Vernon streets to the Westinghouse Electric and Manufacturing Company. It will furnish six 1,500-horse power Westinghouse engines, direct connected to six generators of the same power.

Chicago.—"Lake Street Elevated officials," says the *Herald*, "are planning for a downtown loop of their own to extend from the present terminus at Market and Madison streets east to Wabash avenue, north to Lake street on Wabash avenue, and west on Lake street to a junction with its tracks on Market street. If the right of way and an ordinance can be secured the company will change its motive power from steam to electricity and dispose of the steam engines now in use. Before the first day of January, 1894, the Lake Street Elevated Railway Company will submit an ordinance to the city council providing for an extension of its line above detailed."—The Metropolitan Elevated Railroad Company has purchased from the city for $100,000 the electric lighting plant in the block bounded by Throop, Congress and Van Buren streets and Centre avenue as it was in the way of a proposed extension of its line. It is expected that the city will be able to put up a new building, with new machinery, for less than $100,000. There will therefore be left a considerable sum for the extension of the electric lighting system on the West Side.

The Fishkill Landing Machine Company.

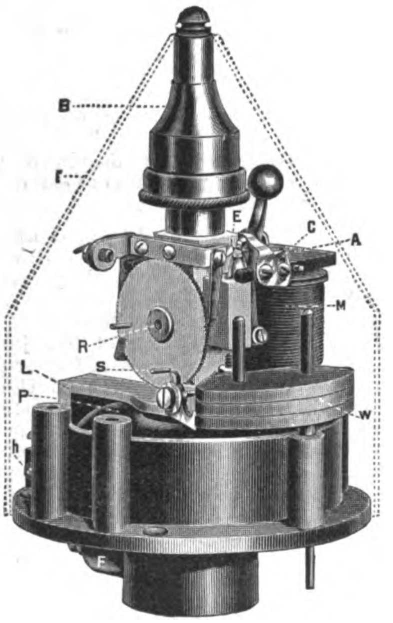
The Fishkill Landing Machine Company, Fishkill-on-the-Hudson, N. Y., builders of the improved Fishkill-Corliss Engine, are doing a large business. Their engines are in demand by all kinds of manufacturers and are also used for electric lighting and street car purposes. The Rochester (N. Y.) Electric Light Company are using a Fishkill-Corliss engine of 500 h. p.

Among the larger engines which they have recently erected are two of 300 h. p. each for the Atlas Cement Company, at Coplay, Pa.; one of 250 h. p. for the Grand Central Palace, New York City, where the World's Fair Exhibition is now being held; one of 175 h. p. for R. M. Wilson, Rome, N. Y.; one 175 h. p. for F. Hosch, Brooklyn, N. Y.; one 250 and one 100 h. p. for the Canda Manufacturing Company's Car Works, at Carteret, N. J.; one 100 h. p. for the Smith Premier Typewriter Company, Syracuse, N. Y.; one 175 h. p. for the Cortland (N. Y.) Wagon Company; one 200 h. p. for David Miller, New York; one 100 h. p. for the Eastman Kodak Company, Rochester, N. Y.; one 300 h. p. for the Metropolitan Realty Company, New York; one 200 h. p. for the National Casket Company, Oneida, N. Y.; one 300 h. p. for the Glen Falls Paper Mill Company, Fort Edward, N. Y.; one 250 h. p. for Kinney Bros., New York; and one each of 300 and 350 h. p. for sugar plantations in Cuba. It will be recalled that the engines for the immense grain elevators of the New York Central and Hudson River Railroad Company, New York City, and the West Shore Railroad, at Weehawken, N. J. (one of 1,000 and one of 800 h. p.), were built by this company, as well as those in use in many of the largest elevators in the Western cities. The officers of the Fishkill Landing Machine Company are Robt. J. Haigin, president; W. F. Sage, vice-president, and Jas. L. Teller, secretary.

A New System of Lighting and Extinguishing Street Gas Lamps Without the Use of Wires.

The Cutler system of gas lighting discards overhead wires and the expensive underground circuit, and adopts an entirely new and inexpensive method. Each lamp is supplied with two sal ammoniac batteries and a spark coil placed in an iron box buried in the ground at the foot of the post. In the lantern is a miniature gas holder about two cubic inches capacity, pivoted on a hinge and held down by weights, and directly over this holder is an automatic gas lighter similar to those used in houses, only much simpler, larger and stronger. Two wires about ten feet long connect the lighter with the batteries through the post. Such an installation is under complete control from the gas works. When it is desired to light the lamps of a city, it is only necessary to open a valve connecting one of the large gas holders at the works direct with the gas mains. This results in a decided increase of pressure in the gas all over the city sufficient to cause all the little gas holders in the lamp posts to lift up about one-eighth of an inch against a platinum stop, and thus close the local battery circuit at each post. The automatic lighter being then supplied with current, immediately turns on and lights the gas.

The cut below shows the lighter. P is the pressure gauge or gas holder sealed with mercury and held down by the weights W. When the gauge lifts, it closes the electric circuit through the magnet M ; the armature A is attracted and caused to vibrate, throwing sparks at E and turning the ratchet wheel R. The first movement of the ratchet wheel admits the gas to a small auxiliary outlet at E, as well as to the main burner. The electric sparks formed at E ignite the auxiliary jet, which immediately shoots up and lights the main burner. As the ratchet wheel continues to turn, the auxiliary jet is closed, leaving the main burner open. The ratchet wheel is finally stopped with the gas turned full on and lighted by a pin in the wheel striking against a stop S attached to the pressure gauge P.



The Cutler Gas Lighting System.

It has been shown in practice that fifteen seconds is amply sufficient for maintaining this increased pressure to give time to make the increase everywhere felt. It can then be brought back to normal pressure when the pressure gauge P will drop back and open the electric circuit. This operation, if repeated, will extinguish the lamps.

The mechanism of the lighter is extremely simple, and made so strong as to insure it from getting out of order or requiring attention of any kind. A heavy cast iron shell, three-sixteenths of an inch thick, shown by dotted lines in the cut, entirely surrounds the mechanism and thoroughly protects it from all kinds of external abuse. No part of the lighter is exposed except the lava tip, which is easily replaced should it become stopped up or broken. An outlet at P provides a passage for pouring in alcohol should the gas freeze in the riser pipe in winter. The iron battery boxes are supplied with covers flush with the ground, which are intended to be removed once a year for cleaning the batteries. This operation constitutes the entire operating expenses.

Complete outfits of this system of gas lighting can be obtained by addressing the manufacturers, the Cutler-Hammer Manufacturing Company, 247 South Jefferson street, Chicago.

The "Mac Tape."

The "Mac Tape" has superior insulating qualities; is guaranteed to withstand the severest climatic changes; is not affected by acids and possesses many meritorious qualities. It sticks to the wire and not to the hands and will not oxidize the wire. Its adhesive qualities are such that it is practically indestructible, and hence will not deteriorate with age. It is specially adapted for armature and field magnet wrapping. When ordering please be careful to state whether black or white is desired. It is put up in ¾ inch widths and in half pound packages. Special widths furnished to order. Beware of imitations. None genuine unless the words "Mac Tape" are on every roll. Made by the Metropolitan Electric Company, Chicago.

INCORPORATIONS.

The American Signal Company, Baltimore, Md.—to manufacture electrical and other machinery. Capital stock, $5,000. Promoters: G. E. Patterson, W. M. Stewart, H. M. Benzinger, G. W. Smith, R. O'Toole.

The Montana Construction Company, Helena, Mont.—to contract for construction of railways and tramways, manufactures of all kinds, water rights, and powers, electric plants and real estate. Capital stock, $150,000. Promoters: Henry Elling, Richard A. Harlow and Samuel Word.

Weaver Electric Company, Jackson, Miss.—to manufacture and sell all kinds of electric and telegraph instruments, invented, improved or acquired by said company. Capital stock, $20,000. Promoters: A. P. Weaver, Wm. Watson, W. W. Stone, W. D. Holder, A. L. Jukiene, R. J. Hardin and T. M. Henry, Jackson.

The Tiffin and Inter-Urban Consolidated Railway Company, Tiffin, Ohio.—to construct street railways, to be operated by electric, steam, cable, horse or other motive power, etc. Capital stock, $800,000. Promoters: Thos. B. Williams, Chas. F. Williams, Frank W. Brihtman, Nelson W. Miller, Meshech Frost, Amandus Betts, Rollo W. Brown and Tunison T. Rosendale.

The Flatbush (L. I.) Gas Company has filed a certificate with the Secretary of State at Albany announcing that it proposes to extend its objects so as to include the manufacture and use of electricity for producing light, heat and power. It also announces that it has acquired the property and rights of the Knickerbocker Electric Light and Power Company of Flatbush. The capital stock of the Flatbush Gas Company has been increased from $150,000 to $200,000.

The Electric Cash Carrier and Change Maker Company, Kansas City, Mo.—to manufacture and sell store service apparatus for making change. Capital stock, $100,000. Incorporators: George P. Gross, Mark Coppinger, Charles A. Gaiser and Charles A. McKiernan, of Kansas City, Edwin R. Gill, of Independence.

The New York and East River Gas Company, New York City—to carry on the business of manufacturing and supplying gas and electricity in New York and elsewhere, for lighting, heating and power purposes. Capital stock, $700,000. Directors: Michael Coleman, Samuel B. Lawrence and William T. Barnard, of New York City; John B. Summerfield, of Brooklyn, and William C. Houston, Jr., of Philadelphia.

The Russ Fender Company (incorporated in W. Va.), Washington, D. C.—to furnish steam, electric, cable and other cars with safety fenders and other appliances to prevent accidents, etc. Capital stock, $250,000. Promoters: Alamando B. Russ, Chicago; A. Hotchkiss, Baltimore; H. H. Blackburn, Washington, D. C.

The Oakland Water Company, San Francisco, Cal.—to supply cities and towns with water and deal in and operate water works, electric light and power. Capital stock, $3,000,000. Promoters: Alviniza Hayward, Andrew Rose, Jr., San Mateo, Cal.; Wm. J. Dingee, Oakland; H. G. Stevenson, Menlo Park; W. E. Sell, Berkeley.

Soldiers' Grove Electric Company, Soldiers' Grove, Wis. —to build and operate an electric plant at Soldiers' Grove, Wis. Capital stock, $1,500. Promoters: Attley Peterson, M. B. Seward, F. P. Priggs.

ELECTRICAL PATENT RECORD.

Letters Patent Issued December 12, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

510,485. Trolley Wire Support. Leroy S. Pfouts, Canton, Ohio. Filed July 19, 1893.
510,600. Speed Reducing and Power Multiplying Hydraulic Gear for Electric Railroad Cars. William Hochhausen, Brooklyn, N. Y. Filed Dec. 26, 1890.
510,634. Electric Railway Conduit. William R. DeVoe, Shreveport, La. Filed July 20, 1893.
510,647. Conduit Electric Railway. John P. Michiell, San Francisco, Cal. Filed July 14, 1893.
510,661. Electric Car Truck. Charles P. Winkler, Troy, N. Y. Filed Nov. 26, 1892.
510,850. Closed Conduit System for Electric Railways. Robert A. Elliott, Birmingham, Ala. Filed July 5, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

510,486. Electric Lamp Support. James J. Renehan, New Britain, Conn. Filed March 20, 1893.
510,479. Electric Light Tower. Hiram Jones, Detroit, Mich. Filed March 10, 1893.
510,605. Electric Arc Lamp. Jesse F. Keser, La Grande, Ill., assignor to the F. P. Little Electrical Construction and Supply Company, Buffalo, N. Y. Filed April 24, 1893.

MOTORS, DYNAMOS, ETC.

510,460. Dynamo-Electric Machine. David H. Wilson, Chicago, Ill. Filed Dec. 27, 1892.
510,465. Regulator for Dynamo-Electric Machines. Louis Bell, Boston, Mass., assignor to the General Electric Company, same place. Filed April 3, 1893.
510,472. Dynamo-Electric Machine. Rudolf Eickemeyer, Yonkers, N. Y. Filed May 23, 1889.
510,487. System of Electric Distribution. Edwin W. Rice, Jr., Swampscott, assignor to the General Electric Company, Boston, Mass. Filed July 10, 1893.
510,534. Rotary Current Motor. Johannes H. F. Gorges, Berlin, Germany, assignor to Siemens & Halske, same place. Filed April 30, 1891.
510,596. Reversing Switch for Electric Motors. John G. Germann, Erie, Pa. Filed April 19, 1893.
510,601. Alternating Current Motor. William Hochhausen, Brooklyn, N. Y. Filed Sept. 4, 1891.
510,602. Dynamo-Electric Regulator for an Engine Driving a Generator. Rudolph M. Hunter, Philadelphia, Pa., assignor to the Thomson-Houston Electric Company of Connecticut. Filed Oct. 29, 1892.
510,603. Power Applying Device for Electric Motors. Arthur H. Johnson, Rahway, N. J., assignor to the Hall Signal Company of New York and Maine. Filed Dec. 15, 1892.
510,662. Electric Motor. Charles F. Winkler, Troy, N. Y. Filed Dec. 24, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

510,430. Telegraph or Telephone System. Wallace R. Kirk, Kansas City, Mo. Filed Nov. 3, 1892.
510,508. Simultaneous Telegraphy and Telephony. Silas W. Holman, Boston, Mass. Filed May 31, 1893.
510,535. Telephone Toll Apparatus. William Gray, Hartford, Conn., assignor of one-half to Charles Soby, same place. Filed May 21, 1889.
510,612. System of Telegraphy. Charles J. Reed, Orange, N. J., assignor of one-half to Gustav Stahl, Philadelphia, Pa. Filed April 12, 1892.
510,863. Telephone Exchange System. William W. Jacques, Newton, assignor to the American Bell Telephone Company, Boston, Mass. Filed Dec. 1, 1892.

BATTERIES.

510,604. Electric Battery. Louis F. Johnson, Poughkeepsie, N. Y. Filed July 11, 1893.
510,808. Machine for Making Storage Battery Grids. Robert M. Lloyd, New York, N. Y. Filed Oct. 31, 1892.

MISCELLANEOUS.

510,417. Range-Indicator. Bradley A. Fiske, U. S. Navy. Filed March 3, 1893.
510,418. Position-Finder. Bradley A. Fiske, U. S. Navy. Filed April 10, 1893.
510,457. Electric-Call System. Samuel Whitehall, South Bend, and Euphrates W. Whitehall, Attica, Ind. Filed March 7, 1893.
510,466. Electric Fan. Edwin H. Bennett, Jr., Bayonne, N. J. Filed October 17, 1891.
510,533. Electric Switch. Jacob S. Gibbs, Hartford, Conn., assignor to the Perkins Electric Switch Manufacturing Company, same place. Filed March 15, 1893.
510,540. Push-Button. Rudolph M. Hunter, Philadelphia, Pa. Filed April 3, 1891.
510,613. Magneto-Electric Induction Apparatus. Chas. J. Reed, Orange, N. J., assignor of one-half to Gustav Stahl, Philadelphia, Pa. Filed Sept. 10, 1892.
510,640. Electric-Current Transformers. William H. Hornberger, Elkhart, Ind. Filed March 31, 1893.

RE-ISSUE.

11,395. Electric Snap-Switch. Gerald W. Hart, Windsor, assignor, by direct and mesne assignments, to the Hart & Hegeman Manufacturing Company, Hartford, Conn. Filed Feb. 13, 1893. Original No. 459,706, dated Sept. 15, 1891.

To Inventors and Others.

United States and Foreign Patents Procured.

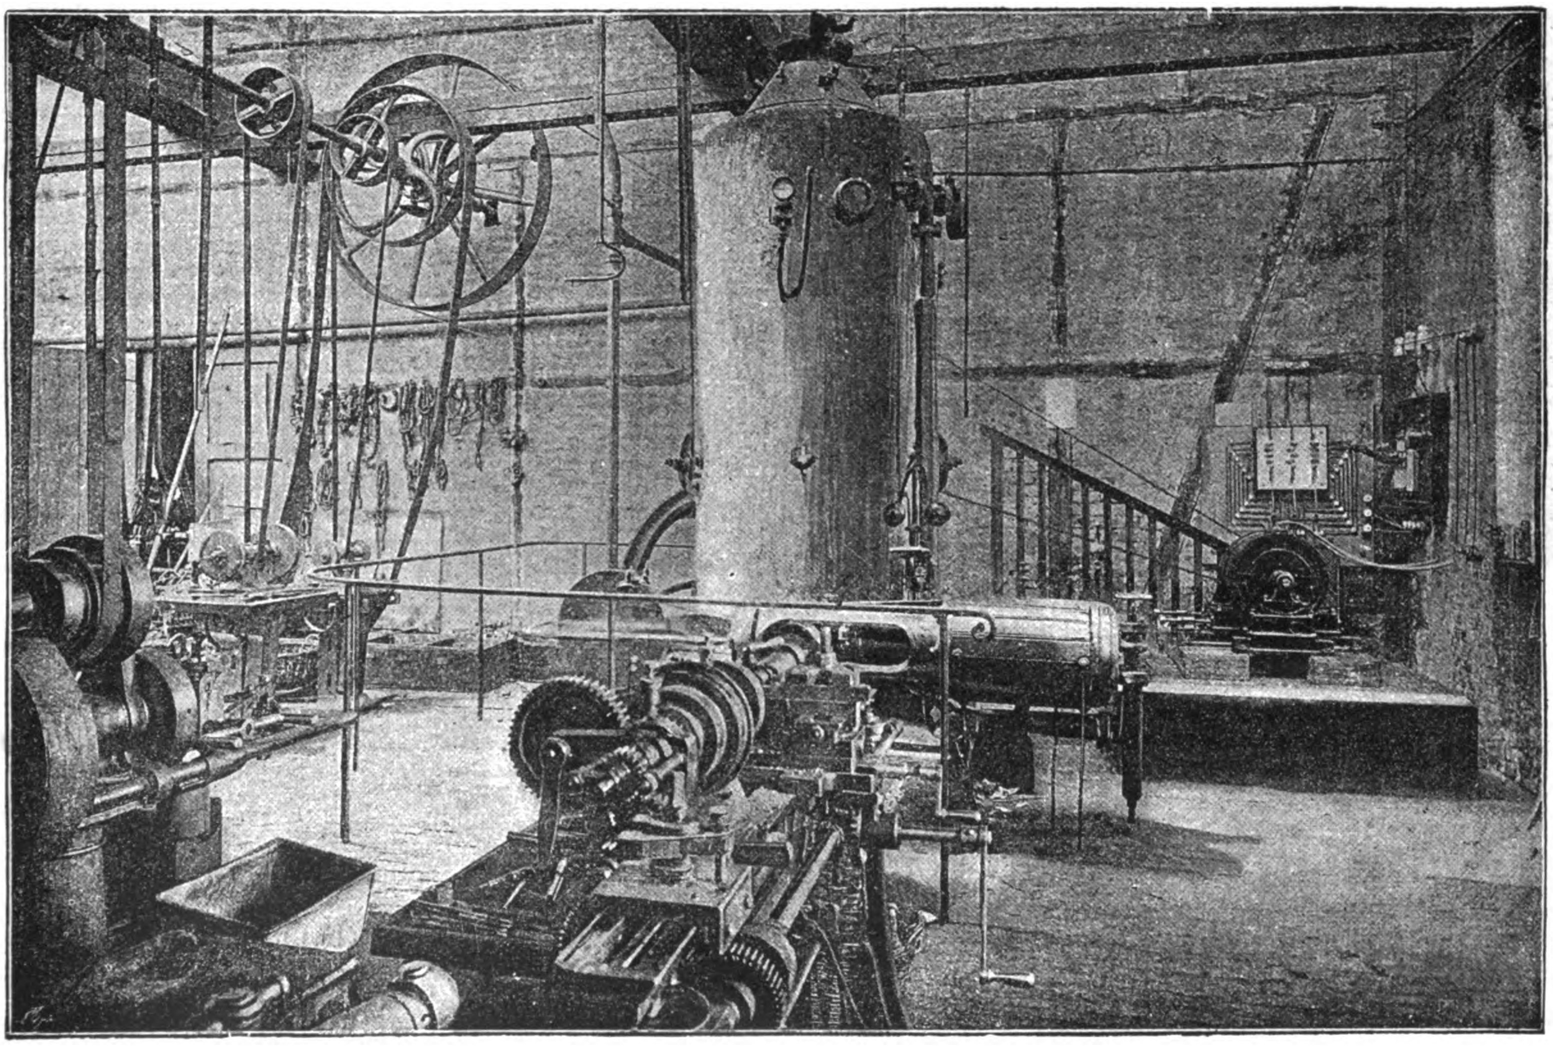
A PATENT DEPARTMENT has been established in connection with the publication office of Electricity, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department Electricity,
6 Park Place, New York City.

ELECTRICITY.

Vol. V. New York. JANUARY 3, 1894. Chicago. No. 25



SCREW FACTORY, RUN WITH TRIPHASE MOTOR. (See Page 294.)

The Bockenheim Triphase System.

The distribution of current by the multiphase alternating system is still a comparative novelty in the electrical field, and plants operating on this system are therefore of special interest at this time. Such a one is in operation in Bockenheim, Frankfort, which includes what might be called a mixed system, the long distance transmission being on the multiphase plan and the local distribution being with continuous currents.

The building in which the station is situated comprises two main rooms separated by a partition wall, the first being occupied by the boilers and the second by the machinery. The boiler house also contains the accumulator room, office and store-room.

The boilers, of the tubular type, are two in number, having 95 square meters of heating surface, and are worked at 150 pounds pressure. A reserve space has been provided for two extra boilers of the same size. The boiler feed is supplied by a steam pump and two injectors. The water which serves the condensers is carried to an apparatus in which it is cooled at the rate of from 50 to 60 cubic meters an hour and is then returned to the source of supply.

There are two engines, each having a capacity of 250 horse power, of the tandem compound type, and are run condensing. These are made by Pokorny & Wittekind, of Bockenheim. The diameter of the high pressure cylinders is 40 centimeters and that of the low pressure 60 centimeters, length of stroke 85 centimeters, and speed 100 revolutions per minute.

Each of the engines is coupled direct to a triphase dynamo of 130 K. W. at a pressure of 80 volts, and also drives by means of a belt a continuous current machine of 36.8 K. W. capacity at 110 volts. From the latter a continuous current is supplied to the 48 poles of the triphase machines by which their fields are excited. The direct current machines are of the Lahmeyer system, and a general view of the station is shown in Fig. 1.

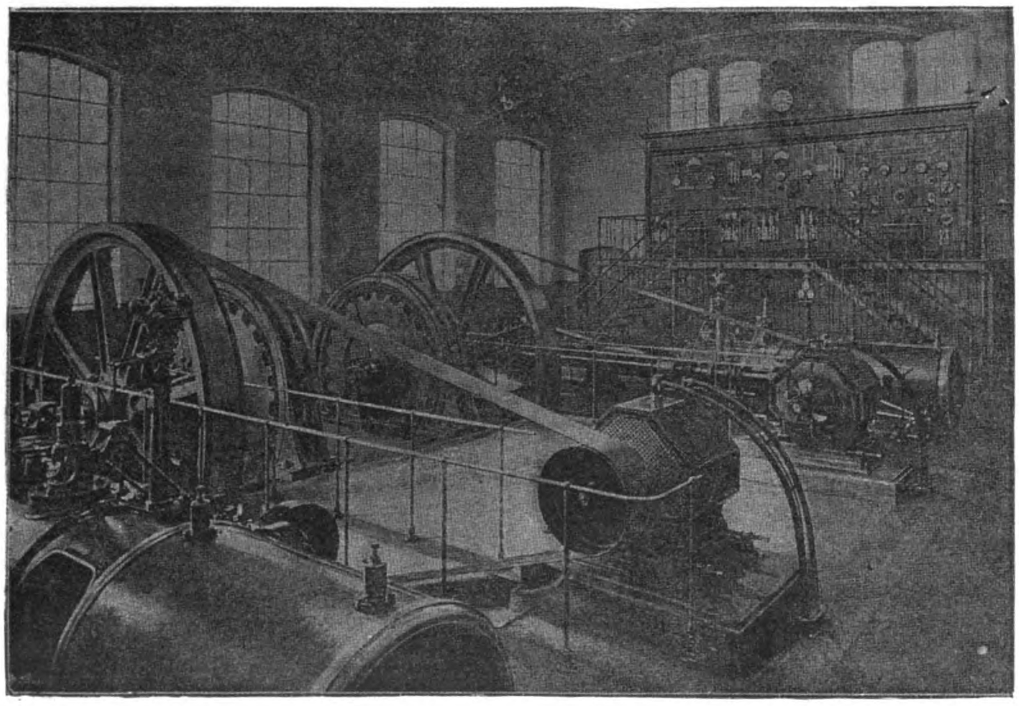


FIG. 1.

The distributing system includes both the direct and triphase. The two direct current machines are coupled in parallel and are led to the bus bars on the switchboard, from which the outside system is supplied directly, and a battery of accumulators and the fields of the triphase machines are also run on these machines. Either the dynamos or the battery can be used to supply the exciting current.

Each of the triphase dynamos are connected to a set of distributing bars by three lines in one of which an ampere meter is placed and each of which has a switch. These are the low tension bus bars, having only 80 volts difference of potential between them. There are phase indicators which are connected with both machines in order to facilitate the operation of throwing the dynamos in parallel.

Three other bus bars are placed near the point where the triphase circuit leaves the building, and these are connected to the low tension bars by means of transformers which raise the voltage from 80 to 700 volts, at which pressure the current is distributed.

The accumulators are of the Tudor type and there are 64 cells in the battery. Its capacity is 450 ampere-hours and its maximum discharge 143 amperes.

The lines for the continuous current distribution are lead-covered cables buried in the ground without further protection. The cables for the triphase system are also lead-armored cables but with concentric conductors having a cross section of 3.7 square millimeters. In the outside of the city, which is a manufacturing district, aerial wires have been run with bare copper, which largely reduced the cost of construction. Thomson lightning-arresters are placed at intervals along this part of the line.

About 1,200 meters from the central station is a sub-station which contains two transformers of 25 K. W. capacity each. One of these is in constant use and the other is held in reserve. They convert the high tension triphase current into a low tension direct current which is used for local distribution. The converter is a dynamotor in which the motor armature is run by the triphase system and drives a direct current generator armature. In this way the triphase system is used simply to transmit the power over long distances while the distributing lines are run on the usual low tension direct current system.

This station is of interest on account of the various applications of electric motors which have been made there. The type of motors usually employed are connected directly to the mains of the triphase system without the interposition of transformers, and from a practical standpoint this operation has been very satisfactory, their care only demanding the replenishing of the oil cups every two or three weeks. The service already includes about 15 triphase motors of capacities varying from 3 K. W. to 15 K. W. which are in use in the neighboring manufacturing and machine shops. The Frontispiece shows a screw factory in which the steam engine has been replaced by a triphase motor. A number of direct current motors are also in use on the low pressure system.

The price of the current is graded for different kinds of service, lighting, constant current motors and multiphase motors being fixed at different prices, which are subject to discounts varying from 7 per cent. to 30 per cent. according to the length of time and the amount of power supplied.

University Extension in the Electrical Field.

The Brotherhood of Electrical Workers Inaugurates a Progressive Educational Plan.

Local Union 3 of the Brotherhood of Inside Electrical Workers has taken the lead in a new movement looking to the intellectual benefit of its members, and for some time to come the course of lectures which its members have helped to bring about will be the centre of interest among a large number of practical workers.

The union has organized a club under the name of the Electrical Workers' University Extension Club, with 400 members, under the auspices of which there will be given, with the co-operation of Columbia College and President Seth Low, a course of ten lectures on electricity and its practical uses, the first of which will be delivered in Cooper Union on the 15th instant.

President Low has contributed $1,000, and the various firms of the Electrical Contractors' Association have also contributed generously. The union's club has raised $800 for the course, each member taking a ticket at the rate of $2 for the whole ten lectures.

That part of the public which is interested will have to pay 25 cents admission to each lecture.

After the first discourse a class will be organized for those who wish to follow up the lectures. The class will be under the direction of W. H. Freedman, tutor of electricity in Columbia College.

A prominent officer of the union says: "It is the ambition of Local Union 3 to rise above strikes and boycotts, and to educate its members for their own good. The strikes of 1892 cost this union $25,000, and the return was comparatively small. The foundation of the present educational movement was the establishment of an examining board last July.

"The electrical trade," he continued, "is second to none in its demands upon the intellectual ability of the workman as well as his mechanical skill."

First Lecture—C. O. Mailloux, "Batteries: primary, secondary and thermo."
Second Lecture—S. S. Wheeler, S. C., "Dynamos and Motors. Direct current."
Third Lecture—W. F. Stanley, "Dynamos and Motors. Alternating current."
Fourth Lecture—A. E. Kennelly, "Electrical Measurements."
Fifth Lecture—F. B. Crocker, "Lighting."
Sixth Lecture—Nikola Tesla, "Power."
Seventh Lecture—T. C. Martin, "Street Railways."
Eighth Lecture—W. Maver, Jr., "Telegraphy."
Ninth Lecture—Also by Mr. Maver, "Alarms."
Tenth Lecture—J. J. Carty, "Telephones."

A Large Contract.

The contract for the structural steel to be used in the construction of the immense new plant of the Westinghouse Electric and Manufacturing Company at Wilmerding has been awarded to the Carnegie Steel Company.

There were several bidders and the competition was extremely lively. Carnegie & Company's figures were considerably under those of the other firms.

PATENT LITIGATION.

A Final Effort to be Made to Crush Competition.

PAPERS ALREADY PREPARED FOR A VIGOROUS CAMPAIGN.

INJUSTICE AND WEAKNESS OF THE PATENTS.

Is the General Electric Company Digging its Own Grave?

I····THE EDISON FEEDER AND MAIN PATENT.

In the issue of ELECTRICITY for December 27 our views on patent litigation were plainly expressed. We have been made aware during the past week that a large proportion of our readers agree fully with our view of the case. Not so the General Electric Company.

It is now the well-matured plan of this company to practise rigid economy in all departments save one, the *legal department.*

New arrangements with counsel have been made, and explicit orders have been given for a vigorous and relentless campaign of patent litigation. Manufacturers, contractors, and users are all to be sued, and with as much celerity as is possible. A half dozen suits have already been begun on other than lamp patents, and twice as many more are already prepared and will no doubt be announced early in January. It is the firm conviction of the New York element in the management that by a multiplicity of suits the desired monopoly may yet be achieved, and that even if the campaign fail ultimately, contractors and builders will be thoroughly intimidated, and will at least purchase no new apparatus from the manufacturers who are under suit.

The situation is in our judgment more critical than at any previous time in the history of the General Electric Company.

There is only one plan possible whereby the business of independent concerns can be saved from irreparable injury and an open market for their wares retained: they must stand shoulder to shoulder, united in defence against the attacks of a common enemy. Many of the patents which the General Electric Company seeks to sustain, and upon which these suits are based, are positively ridiculous, and an intelligent and honest defence is all that is required for their overthrow; but the small contractor cannot and should not be expected to make the defence without the assistance of others who are in equal danger from suits later on.

The General Electric Company is evidently not discouraged by the unfortunate results of the lamp litigation, and has learned nothing of wisdom therefrom.

The feeder and main patent already has a decision of a United States Circuit Court Judge in its favor, however unjust that decision may seem to practical men. Other patents to be fought over are the Edison patents on compound wound machines, the three-wire system, sockets, cut-outs, and even fuses.

In the line of its established policy to do whatever is possible to bring about a new era in the business, when patent extortion and injustice may be wiped out forever, ELECTRICITY will consider carefully the merits of these various patents, trusting that we may be able to throw some new light on the subject.

The first article of the series will be devoted to the

FEEDER AND MAIN PATENT

and a review of the Trenton case, as follows:

The interest which was aroused last winter by the trial of the case of the Edison Electric Light Company against Westinghouse, Church, Kerr & Company, involving the validity of the patent of Thomas A. Edison on what has become known as the "Feeder and Main System," culminated in the decision of Judge Green upholding the patent.

Important as this decision was thought to be at the time, its full force was probably not appreciated until recently, when the General Electric Company sought and obtained an injunction against a contractor because it appeared that in the fulfilment of a contract which he had taken he *intended* to use methods which in accordance with Judge Green's decision were infringements of the patents referred to.

The claims relied on by the complainant read as follows:

1. A consumption circuit, in the main conductors of which the drop in tension is not sufficient to vary practically the candle power of the lamps connected therewith, in combination with feeding conductors connecting the consumption circuit with the source of electrical energy, and having no translating devices connected therewith, the drop in tension upon such feeding conductors not affecting the relative candle power of the lamps of the consumption circuit, substantially as set forth.

2. A consumption circuit, in the main conductors of which there is a definite small drop in tension, not sufficient to vary practically the candle power of the lamps connected therewith, in combination with feeding conductors connecting the consumption circuit with the source of electrical energy, and having no translating devices connected therewith, the loss upon such feeding conductors being greater than upon the main conductors of the consumption circuit, substantially as set forth.

3. The combination of a consumption circuit, in the main conductors of which the drop in tension is not sufficient to vary practically the candle power of the lamps connected therewith, with a feeding circuit having no translating devices, and extending from the source of electrical energy to the centre of the consumption circuit, substantially as set forth.

The patent in question was granted to Edison on September 19, 1882, and the alleged infringement was the construction and operation of an electric light plant in the city of Trenton, N. J. Judge Green's decision was filed in the United States Circuit Court at Trenton, April 10, 1893.

It was evident that if Edison's patent was valid it practically controlled not only the distribution of current for lighting purposes but also for power where the multiphase arc system is used.

The defendants by their answer denied infringement and insisted that there was no patentable novelty in the alleged invention, contending that it had been anticipated by various preceding patents, viz., of Werdermann, Lane Fox, Khotinsky and Sawyer & Man, and had been described in numerous scientific and technical publications (the description of the method of distribution of current to the electro-plating tanks of the Roberts & Havell plant, devised by Edward Weston, which appeared in the *Scientific American*, being an instance in point), and that the systems of gas and water supply now customarily in use in large cities were entirely analogous and similar to the scheme devised by Edison for electrical distribution.

Judge Green, after having heard a great deal of "expert" testimony on both sides, rendered a decision which had no uncertain sound, upholding the validity of the Edison patent, and so far-reaching has been this decision that it seems that any one *intending* to erect an incandescent lighting plant may be enjoined or restrained from proceeding to carry out his intention, without a hearing, under penalty of contempt.

Inasmuch as the feeder system is now almost universally used in the distribution of current for incandescent lighting, if on final hearing in the higher courts Judge Green's decision is affirmed, it means disaster to everyone engaged in this business who has not made his peace with the General Electric Company, or so at least they would have it understood.

It therefore becomes of interest to study the reasons upon which Judge Green founded his opinion, to discover, if possible, some hope for a reversal on appeal. Fortunately for us, he has given them at length in his Opinion, which fills a pamphlet of 48 pages, in which he gives in clear and unmistakable terms the testimony that led him to his conclusion.

Unversed in science himself, as he freely admits, he has had to rely upon the statements of so-called expert testimony, and that which impressed him the most, whether logical or not, was that which governed.

This brings us at once to the question of the weight which should be given to expert testimony. Of the value of *disinterested* expert testimony there can be no question, but we have little of that now before the courts, and there was none in the case in question. When the so-called expert is hired by and paid by either side he is neither hired nor paid to give disinterested testimony, nor is he longer a disinterested party. He is hired and paid, like the attorneys in the case, to present in the best possible form that side of the question and those facts which will assist his client the most. He not infrequently directs both the examination of the witnesses and the general conduct of the case, and in this way becomes an advocate for his client just as truly as are the attorneys. Why then should his statements be given any more weight than those of the attorney?

Let us see what the sources of inspiration were that influenced Judge Green's mind.

The leading experts for the General Electric Company were W. J. Jenks, Lord Kelvin and Dr. C. F. Chandler. These three were more frequently quoted in Judge Green's Opinion than any other witnesses on their side. Mr. Jenks, as is well known, has for years been a salaried employee of the plaintiff company, one of his chief duties being on occasions of this kind to appear in the rôle of an expert witness in behalf of the Edison interests, and that his services have been retained so long speaks well for his fidelity to his duties. That he is an expert in some things, and an honorable gentleman, there is probably no question, but that he is an *electrical* expert on whose testimony far-reaching judicial opinions can be safely founded, no man of prominence in the electrical field would for a moment admit. In fact, he so far disabused the electrical world of any such notion, if it ever existed, by a communication to one of the electrical journals about the time that this suit was pending, in which he showed his absolute ignorance of the very A B C's of electricity, that it would seem he would never again attempt to instruct a judge or a jury.

Lord Kelvin is a man whom the whole world delights to honor, and there is no one now living who has done more for the advancement of abstract science than he, or whose name is more intimately associated with its progress than his. The weight of his testimony is therefore deservedly great, but his testimony was obtained for the plaintiffs by this same Mr. Jenks, who went to England for the purpose, and he was therefore presumably retained by that side.

When Lord Kelvin stated in substance that to the best of his knowledge there was no practicable method known to science of distributing current to incandescent lamps prior to Edison's invention of the feeder system, though this was testimony of a purely negative character, it must naturally have had great influence upon those who suppose that because a man is eminent in one branch of science, or in many, he must be conversant with every development in that science, or the many. But even Lord Kelvin is fallible, and the fact that he did not know that such a system was in existence before the issue of the Edison patent is not conclusive evidence that it did not exist. As evidence of his fallibility may be cited the enthusiasm with which he proclaimed the accomplishment of a great scientific triumph, when in 1881 he exhibited the little storage battery of Faure with its 1,200,000 foot pounds of electrical energy, that he had carried across the Channel to England. These large figures and his enthusiasm set investors wild, who did not know that the former represented but about the same amount of energy as is locked up in a half ounce of good coal, and that the latter was due to a remarkable ignorance of easily ascertained facts; but the result was, as one writer expresses it, that "the shores of Old England are strewn with the wreckage of secondary battery ventures, and the bones of many a victim lie bleaching in the sun."

Nor has he alone shown himself fallible in his knowledge of the practical application of electricity, with which he has had far less to do than with the more purely theoretical or scientific. There is no branch of electrical development with which Lord Kelvin's name is more closely identified than that which includes instruments of precision for the measurement of the current and other electrical phenomena. In these the question of suitable materials for resistances is of paramount importance, and the world has been striving for years to discover a substance whose temperature coefficient should approach more closely to zero than German silver or platinoid. Since the accuracy of these instruments, the designing of which has formed an important part of Lord Kelvin's life work, depends very largely upon the discovery of a metal or alloy which has a very low temperature coefficient that is constant through a reasonably wide range of temperature, one would think it entirely safe to assume that Sir William Thompson, or Lord Kelvin as he is now called, would know everything that had been accomplished in that line. But it seems that his knowledge even in this, his own special line, is deficient. Some time ago several of Prof. Von Helmholtz's assistants in the Physikalisch Technische Reichsanstalt at Charlottenburg undertook in their official capacity to investigate what had been accomplished in the production of substances having low temperature coefficients, and among others tested by them were three alloys invented some years ago by Edward Weston and *patented* by him, two of which *had a temperature coefficient of zero*, and the other a *small negative coefficient.* These qualities had been claimed by Weston in his patents, and the tests made by these scientists confirmed the remarkable claims that had been made for them, and in their report they so stated officially. Lord Kelvin, in referring to the work of the Reichsanstalt on a recent public occasion, spoke of the *discovery* by these gentlemen of alloys having a zero temperature coefficient, and of one having a coefficient with a negative sign. These gentlemen, however, had not been appointed to the task to discover anything new, nor did they claim to have done so. They gave Mr. Weston the credit of the discovery, though perhaps not in as pronounced a manner as justice would demand, yet Lord Kelvin, if he had been called to testify in court as to whom belonged the glory of this most important discovery—to the assistants in the Reichsanstalt or to Mr. Weston—would have lent the full weight of his mighty name to the former by answering that "so far as my knowledge goes there was no such thing as an alloy having either a zero or negative temperature coefficient known to science prior to the investigations of Prof. Von Helmholtz's assistants in the Physikalisch Technische Reichsanstalt."

It will thus be seen how cautious we must be in assigning importance to testimony of a negative character even when it is given by such a great man as Lord Kelvin.

The third expert for the plaintiff was Dr. C. F. Chandler, who is so well and so favorably known in the domain of chemistry. In his testimony he maintained that the feeder system involved central station control or regulation of the current, and apparently convinced the Judge that it did, though the patent in suit is silent on that subject. In other respects he proved a good witness for the defence, as shown below:

425 x Q.—"Is not the distributing system shown in Fig. 13 of the Werdermann English patent and in the figures of the two Werdermann publications in evidence subdivided into two circuits, one of which constitutes the lamp circuit and the other a supply circuit, *not directly connected with any lamps, and the drop in tension upon which does not affect the relative candle power of the lamps ?*" (This is Claim 1 of the patent.)

A.—"IT IS."

426 x Q.—"If it were assumed that some or all of the lamps supplied by the Werdermann distributing system referred to were at a considerable distance from the dynamo, and that the conductors directly connected to the lamps were made sufficiently large, would not the system embody the third and fourth conditions set forth in your answer to cross question 422 ?"

A.—"*I do not see why it would not.*"

427 x Q.—"If the Werdermann system referred to, under the assumptions of the last question, were used for operating a large number of incandescent lamps of such construction as to be capable of being turned on and off independently by the consumer, would not this system also embody the first and second conditions stated in your answer to cross question 422 ?"

A.—"*I do not see why it would not.*"

428 x Q.—"Then, as I understand you, if the distributing system shown in Fig. 13 of the Werdermann English patent were applied to operating a large number of incandescent lamps, so constructed that they could be turned on and off independently, and some or all of which were at a considerable distance from the dynamo, and if the parts of the conductors directly connected to the lamps were made of sufficient size, the system would embody the four essential conditions of the patent in suit, to which you refer in your answer to cross question 422 ? Is that your opinion ?"

A.—"It would, assuming that the number of lamps is sufficiently large, and the distance is sufficiently great to develop the difficulties of drop in tension, referred to in the specifications of the patent in suit. I would further say that in stating the conditions in my answer to cross question 422 I omitted to mention one point which I think is implied in the first three claims, which is, that the loss on the supply conductors and the mains together would be sufficient, if the lamps were placed on the supply conductors as well as on the mains, to affect the relative candle power of the lamps."

429 x Q.—"If this last condition were present also, would the Werdermann system referred to embody all the essential conditions of the patent in suit as you understand the same ?"

A.—"*I do not see but that it would if it complied with all the conditions stated in the last two questions.*"

Essentially the same questions in regard to the Khotinsky French patent brought out the same admissions. It will be observed in this connection that if these conditions must be written into either of these two patents to make them operative, they must also be written into the patent in suit to make it operative, and Prof. Chandler's admissions would therefore seem to be admissions that these two patents *were anticipations* of Edison's patent.

In regard to the methods employed for equalizing the potential in galvanoplastic operations, which it was urged anticipated Edison, Judge Green says (Opinion, p. 31): "It is difficult indeed to see the least possible analogy between a bath, or a vat, or a tank, containing metal in solution through which an electric current is to be passed, first for the purposes of decomposition, and secondly for a fixing of the decomposed molecules of the metal upon an object temporarily placed in the bath, with a system of electric conductors, feeding and consumption, running for miles, perhaps, *through thickly settled territories*, having upon the consumption circuit incandescent lamps permanently fixed and in large numbers, usable at pleasure and wholly beyond the influence of 'drop in tension.'"

In electro-plating the success of the process is absolutely dependent upon a uniform distribution of potential over the whole surface of the object being plated. If there be but one article in the bath an equal potential must be brought to every surface molecule of that object or the process is a failure. If there are many objects in the same bath the same requirements must be fulfilled for each article as for each surface molecule of the individual piece, and the limits between which a variation is permissible are very minute as compared with those allowable in incandescent lighting. In fact, the requirements in such cases are by far more exacting than those of current distribution for lighting purposes. The same methods to accomplish this distribution as patented by Edison were used prior to his patent, and the methods of proportioning the wires for this purpose was known and arrived at through theory as well as by the teachings of practice. Edison said no more than was already known. His method was to have a feeding circuit in which there should be no translating devices, so arranged thus that however great the drop might be it should not affect the relative pressures upon the translating devices connected to the consumption circuits, which should be of such a size that the drop in the latter would not vary the pressure practically at the terminals of the numerous translating devices connected thereto. A definite object is obtained in a definite way. The same object is in view in electro-plating, and it is accomplished in the same way exactly, only the methods employed in the latter are a refinement, or of a higher type, than in the former, because the permissible variation in an electric lighting circuit would be fatal in electroplating. If, however, they were the same, what difference can it possibly make *what* translating device receives the current? And what earthly bearing has the Judge's statement upon the case that the lighting circuits often run "through thickly settled territories?"

Mr. Weston testified that prior to 1880 he planned and erected a large electro plating works for Roberts & Havell, in which there were a number of depositing tanks, and that the circuits for these were so arranged as to equalize the pressures throughout all of the tanks. Prof. Chandler testified that it seemed *probable* that the consumption mains in this case were made relatively very large for purposes of mechanical strength rather than with the view of equalizing the pressure, and this view Judge Green seemed to take *notwithstanding* the *positive statements of Mr. Weston* that he proportioned them large for the same reason, well known to him at the time, that caused Edison to introduce this feature into his patent.

Judge Green also assigns as a reason why electro-plating practice cannot be compared with lighting practice, that in the former the *electromotive force* "*is of so* LOW *a tension* that it would *be utterly futile to consider it as a possible factor in electric lighting.*"

What a remarkable statement to base an opinion on! Every electrician in the land knows that the difficulties are enormously increased as the tension becomes lower. Every electrician in the land knows that any method of regulation or equalization that will be effective where low tensions are used will be far more efficient as the tensions increase, and that if the tensions permissible were high enough there would be no occasion to use Edison's feeder and main system, or any other system of equalization.

As regards the analogies between gas and water distribution and electrical distribution, which are so close that the law of flow of the latter is expressed in units of the same kind as those used in the two former, the learned Judge quotes Lord Kelvin at length, to show minor differences, who says: "The translating devices used for the electric light *are utterly and essentially different from anything used in gas lighting.*" (The italics are Judge Green's.) But what difference does it make *what* the character of the translating devices is so long as the features of distribution desired obtain? And again he says:

"*There is absolutely no analogy in gas to the electric bridge from one main to another main, such as is constituted by the incandescent light.*" (Italics again Judge Green's.)

If there is no close analogy with gas there certainly is with water, for how does the bridge of water issuing from the faucet and gradually finding its way back to its source by percolation through the earth or otherwise, differ from the electric bridge whose current finds its way back by a second conductor? The analogy is very close between the two, and especially so where a ground return is used for the electric circuit.

Again Lord Kelvin is quoted: "The incandescent light has no regulator in connection with it; it is either off or on."

Lord Kelvin must have forgotten that there are electric lamps provided with just such regulators, and that they are articles of regular manufacture and sale and use in this country if not abroad, but his object was to show that because the consumer of gas had a means of regulating the supply, and the consumer of electricity had not, the requirements of equalization of pressure in the former distribution were not so rigid as in the latter. The Judge quotes Lord Kelvin also for this purpose, yet it has been shown that he discarded the electro-plating system for just the reverse fact, that because of the *low* tension the nicety of regulation required was incomparably greater than that required for lamps.

But when all has been said as to the difference between the flow of different fluids through different classes of conduits, the fact remains that they all conform to Ohm's law, which reads that the rate of flow bears some definite relation to the pressure and the resistance. Different constants or factors must be introduced into the equation for each particular fluid and for each kind of conduit, but the fundamental law is essentially the same. No one will probably deny that Ohm's law holds good for alternating currents, but here the law is modified by the substitution of the square root of the mean squares of the impressed electromotive forces for the impressed pressures, viz., the effective head is substituted for the actual head, and a factor is introduced which differs with each frequency, but how does this differ from the law governing the *flow of water or gas?*

But there are some other facts in the history of electrical development having a most important bearing on this case, which for some unexplained reason were not put in evidence before Judge Green.

It is well known that Edison's application for a patent in Germany in 1882 on this same system was denied. The reasons for rejection of the application were briefly these, as given by the Imperial Patent Office:

"The application contains *no new ideas* for which patent protection is applied for, but treats exclusively upon the scientific question, how the conductors are to be arranged so as to provide with the minimum of conducting material many branch conductors from one electrical source with as even as possible a current. This every electrician intends to do, and solves the question by the *use of generally known scientific principles and methods.*" It is then stated that the basis for this figuring which every educated electrician uses are given in "Kirchoff's Laws on the Distribution of Current," which was published in every physical text-book at that time, and taught in every technical school. It was also stated as a sufficient reason for refusing the application that by the patenting "of such generally known scientific construction principles, industry would be completely restricted."

"The patenting of the principle that the section of the feeding or conducting wire must be in proportion to the strength of the currents which flow through the same, would," say the records, "mean about as much as though somebody would take a patent on the principle that when draining the soil the section of the ditches must correspond to the amount of water which flows through the same."

Edison appealed against this ruling, and the matter was again considered. This appeal is interesting reading, but too long for insertion here. It was again rejected, the following objections having been filed:

"Kirchoff's theories give in fact all the means of arranging the conductors, even in the most complicated cases, so that every lamp receives the same current." And as evidence of prior use, the employment of the system in exploding mines was cited; a circular bearing date of 1870 decribing its employment for other purposes was enclosed; a sketch of its use in 1879 on an electric railway at the Berlin Industrial Exhibition was also enclosed, with the asseveration that the system was "entirely identical with Edison's," and so on, mentioning Gulcher's* lighting system and the system employed to supply current to systems of electric clocks as all being anticipations, and concludes the statement as follows:

"From the above it seems to us as not permissible to patent the means known to every expert to obtain known results in a special case, that of incandescent lamp lighting."

The first decision rejecting the application for patent was confirmed for the following reasons:

"The device mentioned in the two claims recently filed is to be considered as an arrangement of the conductors of an electrical current which is known to every expert and that is generally in use in exploding mines and in electrical clock systems where every working point must receive the same current. The arrangement of the conductors, shown in Fig. 9 of the application, coincides exactly with that which was used in the first electrical railway by Siemens & Halske during the Berlin Industrial Exhibition of 1879. No patentable novelty can be seen in the transfer of this device to special lighting purposes."

---

Franklin Institute Prizes.

The attention of ingenious men and women is hereby directed to the fact that the Franklin Institute of the State of Pennsylvania for the Promotion of the Mechanic Arts may grant, or recommend the grant of, certain medals for meritorious discoveries and inventions which contribute to the promotion of the arts and manufactures.

The character and conditions of these awards are briefly stated in the following:

The Elliott Cresson Medal, founded in 1848 by the gift of the late Elliott Cresson. This medal is of gold, and by the terms of the deed of trust may be granted for some discovery in the arts and sciences, or for the invention or improvement of some useful machine, or for some new process or combination of materials in manufactures, or for ingenuity, skill or perfection in workmanship.

The John Scott Legacy Premium and Medal (twenty dollars and a medal of bronze), awarded by the city of Philadelphia. This medal was founded in 1816 by John Scott, a merchant of Edinburgh, Scotland, who bequeathed to the city of Philadelphia a considerable sum of money, the interest of which should be devoted to rewarding ingenious men and women who make useful inventions. The premium is not to exceed twenty dollars, and the medal is to be of copper and inscribed "To the most deserving."

The control of the Scott Legacy Premium and Medal by Act of the Ordinance of Councils in 1869) passed to the Board of Directors of City Trusts, and has been referred by the Board to its Committee on Minor Trusts, and that committee has resolved that it will receive favorably the name of any person whom the Franklin Institute may from time to time report to the Committee on Minor Trusts as worthy to receive the Scott Legacy Premium and Medal.

The Edward Longstreth Medal of Merit, founded in 1889 by Edward Longstreth, machinist and late member of the Baldwin Locomotive Works. This medal is of silver, and may be awarded for useful invention, important discovery, and meritorious work in, or contributions to, science or the industrial arts.

Full directions as to the manner and form in which applications for the investigation of inventions and discoveries should properly be made will be sent to interested parties on application to WILLIAM H. WAHL; Secretary.

The Navy Yards to Use Electrical Appliances.

The Navy Department at Washington, believing that the use of electrical appliances in the machinery departments of the Navy Yards would result in economy of money and power, has selected a Board to inquire into the advisability of their adoption at the New York and Norfolk Yards. The Board will meet at the Brooklyn Yard at once. It consists of Commander Washburn Maynard, Lieutenant J. D. Murdock and Professor O. G. Dodge, the latter an expert electrician.

ELECTRICITY

The Popular Electrical Journal.

GEORGE R. METCALFE, - - - EDITOR.
R. H. WILLOUGHBY, - - ASSOCIATE EDITOR.

B. E. GREENE, Publisher.

PUBLICATION OFFICES:
6 Park Place - New York

CHICAGO:
J. F CONNOR, - - 823 Monadnock Building

BOSTON:

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

All Aboard for Schenectady.

The decision of the powers that all the offices of the General Electric Company are to be removed to Schenectady immediately created consternation in the ranks of the minor officials when announced on Saturday, and made the "Happy New Year" greeting of the period sound like a mockery and a gibe. The blow has fallen heavily all around, but its effect is particularly crushing in the case of those misguided friends of Mr. Coffin who lost all their money in the stock market, and who really can't afford to move their household effects just now. Several of the gentlemen have quietly expressed their intention of complying with the order, and of remaining in Schenectady until they can find other places, and no longer.

ELECTRICITY congratulates the company on a wise business move, and commiserates the society men who will perforce be compelled to mend their ways. They can console themselves with the reflection, however, that even the Tenderloin has been getting slow of late. The company has now taken its proper place in the procession—near the foot.

For the benefit of those who are not acquainted with the geography of their country, we will state that Schenectady is a small village, lying on the banks of the Mohawk, sixteen miles west-northwest from Albany, which latter town is exactly 145 miles due north of the Hoffman House, 200 miles west of Young's, and the same distance from the Parker House. The town contains about 16,000 souls, mostly contented and prosperous laboring men in the various manufacturing establishments, who rise at 6 A. M. and retire at 9 P. M.

It is an eminently respectable, though not a gay city, founded by the same enterprising Dutch, who first settled Manhattan Island. It is not far from Little Falls, the most important cheese market in the world, where the scenery is acknowledged to be magnificent. It is on the line of the Erie Canal and the New York Central Railroad. All boats and freight trains stop there.

We understand that Messrs. Greene, Ord and others have already grown despondent in contemplation of their enforced absence from Delmonico's, their banishment from the innumerable joys of life in the metropolis, and have unjustly characterized Schenectady as a stupid place. We can assure them that Schenectady is all right. True, they will have to travel a slower gait, and if they would be happy, change their ideas of what constitutes pleasure. Better than they have lived and died there. It is not half so dreary a place as the settlement of Warwick and Coventry in Rhode Island, the ancestral home of the Greenes, and is fully as lively as Princeton, in New Jersey, where Mr. Ord formerly taught the young idea how to shoot.

The country being flat, malaria in its most virulent forms is an ever-present evil; but we are told that the drug stores (of which there are two) make special rates on quinine and cholagogue.

However, life is still worth living, even in Schenectady, and there are many forms of wholesome and innocent enjoyment, as yet, we fear, untried by the gentlemen referred to.

The Edison Hotel, though not on a par with the Imperial or the Plaza, is a very good hotel, and will soon be a scene of wild revelry by night (that is, till 9 P. M.) There will be fierce games of checkers, delirious rubbers of whist, and stories without number of the life which is past and gone.

On holidays and Sundays excursions may be made to the reservation of the Onondagas near Syracuse, where a new kind of "society" can be found.

The General Electric Glee Club will be formed, and "Auld Lang Syne" will be sung with fervor. There will doubtless be many other clubs, including the "O. T. Crosby Zouaves," and the "S. D. Greene Cadets." During the winter there will be ample opportunity for lacrosse and tobogganing, and diverse other healthy sports. In the summer a swimming school could be organized, and a "Cussing Club" will be a necessity the year round.

The newcomers will no doubt be made welcome at the monthly debates of the literary societies of Union College, and those of correct habits will easily find entree to the occasional afternoon teas of the Schenectady matrons. In fact, although it is a state secret, the fame of Mr. Ord's whiskers has preceded him, and he already has several invitations in advance for these events.

On off nights, when there are no other diversions, rides may be taken on Mr. Muir's railroad.

Mr. Ord will, of course, speedily compile a "Book of Etiquette for Electrical Men," something on the plan of his previous "Book of Instructions," which proved so convenient for certain occasions.

Each one may easily adjust himself to the changed conditions of affairs and still enjoy life hugely. The company will save a great deal of money in rent, will get twice as much work out of the men (7 A. M. to 6 P. M), and living being so cheap in Schenectady, a further reduction of 25 per cent. in salaries would certainly not be objected to by any one.

ELECTRICITY'S private telephone will be extended to Schenectady, and we will report the news as heretofore.

……

Electrical Fire Risks.

The interior wiring of buildings is a far more fruitful source of fire than overhead wires, and this class of construction calls for correspondingly greater care than the former. It is only within the past three or four years that interior wiring has been made perfectly safe, and this result has been largely due to the efforts and restrictions of the fire underwriters. Many of the devices used in the early days of incandescent lighting, and which at that time were regarded as thoroughly safe, could not now pass the inspection of any insurance company in the country.

Most all of the fires due to the use of electric lighting have their origin in some part of the wiring of the buildings, as it is almost impossible to start a fire from an incandescent lamp, and where arc lamps are used for interior lighting the globes and screens in general use render them very safe if ordinary care is exercised in keeping them properly trimmed. The chief danger here lurks in the hidden parts of the wiring, where a fire may attain considerable headway before being discovered, but if electric wiring is installed in accordance with the best practice known at present its fire risk would practically disappear. As almost every one familiar with the subject admits the possibility of making interior wiring perfectly safe, it follows that where fires occur from this source the work must be defective in some respect.

Faults in interior wiring may be traced to defective insulation, bad materials or workmanship and insufficient capacity of the wires, all of which may be detected with competent inspection, and which are generally the result of too cheap work. The insulation of any house wiring can be fixed at almost any degree demanded, even without the use of materials other than those commonly employed, if the work is put in by competent persons. The use of tubing in which to run the wires is now general, and this tubing consists of a non-inflammable material covered with a metallic sheathing, with which a complete system of piping is run through the building in the same manner as the gas or water pipes, and is provided with suitable outlets for lamps, switches, etc In addition to the insulation provided by the tubing, the wire which is drawn through it is itself covered with a good quality of insulation, and only wires of one polarity need be run in a single tube. With these precautions and the lines between the various outlets of ample capacity to carry their maximum possible current without excessive heating, no possible danger can arise on this part of the system.

The next point is the connections at the different outlets at which junction boxes of incombustible material should be provided. These contain the switches and fuse blocks, in which sparking and melting of fuse wires will inevitably occur at times, thus strongly arguing the use of only the most approved appliances of this kind. The use of wood or any inflammable material in these appliances should not be tolerated, although the old time wooden bases are by no means obsolete. The apparatus used now, enclosed in slate or porcelain, meets every requirement of safety, but even this may be troublesome unless it is set up with care and is properly used. The chance of poor connections and the introduction of light resistances at these points is always present when this work is handled by any but the most experienced and careful workmen. If these fuse blocks are not properly used in regard to the size of the fuse wire required for the current their use becomes a mere farce. It is certain that a great many cases could be found to day where after the proper size fuse wire has been melted it has been replaced by copper wire of perhaps several times the capacity of the wire it was supposed to protect from overload.

The same difference in quality and make may be found in the electric light fixtures as in the other supplies, but their quality has been steadily improving, and if properly installed are very safe.

The kind of plant here outlined includes the best materials, arrangement and workmanship, and until these conditions are departed from the fire risk from this source is almost nominal. The temptation to cheapen the work, which is frequently given to the highest bidder without even the restriction of any specifications or the oversight of any competent engineer, constantly tends to the introduction of poor materials and workmanship, and it is in this way that electric wiring has obained a far worse reputation than it ought to hold under proper conditions. As there are contractors who will take advantage of the general ignorance of customers on this subject, it is as necessary to secure the services of a competent engineer for this work as it is to engage an architect in building a house.

We have so far, however, considered the subject in its worst aspects and taken the most exaggerated view of its dangers; but it is only fair to say that even with as many poor plants as may be found in use, statistics show the fire losses to have been very small in comparison with all other forms of illumination. Figures taken from 82 cities, recently, show that of the total number of fires from all causes a trifle less than 1¼ per cent. were caused by electric circuits, which makes a very favorable showing in comparison with any other method of illumination or power transmission. It also points to the extreme reliability which electricity would present against fire if the installation of this system was always as perfect as possible, and with the constant improvements which are being made, the risk should be constantly on the decrease.

WE are informed that the resignation of Mr. F. P. Fish has been accepted, and that Messrs. Atterbury, Hyde & Betts will direct the campaign of patent suits now under way.

……o……

To Mr. W. J. Hammer: Your pernicious activity as a spy is likely to excite curiosity as to who and what you are. The drubbing which Grand Sheik A. Hickenlooper gave you is not forgotten, and this curiosity may yet be gratified.

To the Mohawk Flats.

The General Electric Company will Retire to its Lodge in the Wilderness.

The Marble Building at 44 Broad Street, too Expensive a Luxury for Present Conditions.

It was officially announced on Saturday last that the Directors of the General Electric Company have decided to concentrate all the various departments of the business at Schenectady. Electrical, engineering and designing departments are already being removed from the Lynn works. Prof. Thomson will be expected to make Schenectady his headquarters, and Mr. E. W. Rice, Jr., has already received his notice of transfer.

The main offices of the company, heretofore at 44 Broad street, are to be moved to Schenectady by February 1, and the entire force transferred.

The company's magnificent building will be offered for rent to other concerns.

Many discharges have already been announced and more are to follow. Among the important ones so far are those of Messrs. Herrick, Muir and Hughes.

Capt. Eugene Griffen is to go to Chicago to take charge of that office, the only district office remaining.

It is not the Schenectady works, but the Lynn works, which are practically dismantled, and this latest move settles a month in advance of the annual meeting the question as to which element is controlling the policy of this company.

Mr. H. McK. Twombly will no doubt be the next president of the company, and Mr. Coffin will be at the head of a competing organization.

MR. COFFIN HAS SPOKEN.

He Furnishes the Chemical Bank with Grounds for a Slander Suit.

A fall of five points last week in General Electric called forth many rumors, in reply to which Mr. Coffin said officially:

"There is no more danger of General Electric going in receivers' hands than the Chemical Bank. I cannot understand why anybody should put such a report in circulation. Surely no insider would do it who knows the facts. Our relations with the Brush Company are most friendly. We own a very large proportion of the capital stock of the Brush Company. General Electric has practically no floating debt and the company is doing more than one-half the business it was doing last year at this time, and it is doing it on a cash basis. The reduction in the price of lamps was inaugurated by General Electric because the company has been able to manufacture lamps cheaper, and it is thus giving the public the benefit. The relations between the Thomson-Houston interests and those of the General Electric are not strained. On the contrary, they are most friendly."

Which all goes to prove that not even the accumulated troubles of the past six months have been sufficient to destroy Mr. Coffin's sense of humor. He can laugh, and make the whole world laugh with him, whenever he chooses.

Personal.

Mr. Walter C. McKinlock, Secretary of the Metropolitan Electric Company, Chicago, has just returned from a successful business trip, and reports the outlook for his new company as very promising.

Death of William Richardson.

William Richardson, known to every street railway man in the country, and a leading spirit in both the New York State and National Street Railway Associations, died at his home in Brooklyn on the 31st ult. of pneumonia.

Mr. Richardson was seventy-one years old, and had had an active career. He was interested in politics up to twenty years ago, and was a friend of Thurlow Weed, who gave him his original start in the street railway business, as president of the Dry Dock, East Broadway and Battery line in New York.

Legal Notes.

An attachment suit by the General Electric Company against the City Electric Street Railway Company of Little Rock, Ark., was begun a few days ago in the Circuit Court at Pulaski, Ark. The suit involves the legality of claims aggregating nearly $300,000 against the railway company, which is now in the hands of a receiver.

Suit was brought lately in the United States Circuit Court at Portland, Ore., by the Northwest General Electric Company against the East Side Railway Company for the appointment of a receiver and the foreclosure of a mortgage on the road for $67,000, which secures about $37,000 due the Northwest General Electric Company, and $29,000 due the Commercial National Bank. The court granted the application, and, with the consent of all parties to the suit, appointed Joseph Simon receiver of the company's property.

A suit brought by Stephen L. Wilson against the Fort Wayne Electric Company was begun in the Supreme Court, Brooklyn, N. Y., on the 19th ult. The action is brought to recover $6,987 and interest under contract. Wilson, who lives in New Milford, Conn., alleges that the defendant agreed to buy the entire output of his mica mine. The defence claims that the mica is not up to the required standard.

Edward C. Hinman, of Battle Creek, Mich., has been appointed receiver of the Battle Creek Electric Railway Company, and his bond has been fixed at $15,000. The orders were entered by Judge Swan in the United States Circuit Court and as the result of the filing of a bill against the company by the Central Trust Company of New York. When the railway was projected, three or four years ago, the stockholders gave a mortgage on their railway property to the trust company to cover a loan of $110,000. There was a default in the payment of $3,300 interest, due on the first of last July, hence the foreclosure proceedings.

The Falls Rivet and Machine Co. has begun a suit at Toledo, O., against the Toledo Electric Company for a balance of $1,692.15, due on machinery furnished for the electric company's new power house. The parties named as defendants are the General Electric Company, Toledo Electric Company, J. S. Rodgers and John S. Moore, trustees and individually.

The Denver (Col.) *Times* says that the final report of Assignee Theodore Holland of the Montclair Electric Light Company has been approved by Judge Allen and the assignee discharged. The total value of assigned property in Holland's hands was $33,700.78.

Judgment for $10,045 has been entered by default against the Union Electric Company, of No. 45 Broadway, New York, in favor of Stephen R. Bradley, the president of the company, of which Stephen R. Bradley, jr., is secretary and treasurer. The company was incorporated under West Virginia laws in July, 1891, with a capital stock of $500,000, for the manufacture of electric storage batteries.

James N. Cropper has been appointed receiver for the Muncie (Ind.) Electrical Works. The company is a new one, organized by Cleveland capitalists for the manufacture of dynamos. The receiver was appointed to enable a dissolution of partnership.

Recollections of Werner Von Siemens.[*]

VI.—The First Laying of a Deep Sea Cable.

The successful use of copper wires coated with gutta-percha as underground conductors suggested their employment also for submarine telegraphic communication. That sea water was not in any way injurious to the gutta-percha had been proved in the case of the insulated wires connected with the torpedoes in Kiel harbor, which were quite unchanged after the lapse of two years.

The first attempt to connect two sea coasts by means of gutta-percha conductors had been made as early as 1850 by Mr. Brett, who had obtained a concession for a submarine telegraphic communication between Dover and Calais. The unprotected wire laid by him retained its efficiency, as was to be expected, not much longer than the time of the actual laying, if indeed it was ever really serviceable. It was replaced in the following year through Messrs. Newall & Gordon by a conductor armed with iron wires, which acted well for some time. This was the commencement of submarine telegraphy, destined speedily to become one of the most important media of communication.

In September, 1855, Mr. Brett, commissioned by the Mediterranean Extension Telegraph Company, had made the attempt to lay a heavy cable with four conductors between the island of Sardinia and the town of Bona in Algeria. He employed for the purpose the same contrivances as in the North Sea, but unfortunately his brake apparatus did not suffice on reaching deep water, and in consequence the whole cable rolled to the bottom without the possibility of detaining it. When a second attempt in 1856 also miscarried he retired from the undertaking, which was then taken up by Newall & Company. The latter contracted with my firm for the delivery of the electric apparatus, and requested me to undertake the electrical testing on and after the laying.

This first laying of a deep sea cable was both interesting and instructive to me. At the beginning of September, 1857, I went, at Genoa, with an assistant and the necessary electrical apparatus, on board a Sardinian corvette, which was to accompany the expedition and take us to Bona, where the steamship laden with the cable awaited us. It was an interesting company which met on board the war-ship. Besides the English contractors and cable manufacturers, Mr. Newall and Mr. Liddell, there were on board several Italian *savants*, telegraph officials, and naval officers, among them the learned Admiral Lamarmora, a very amiable and well-instructed officer, brother of the well-known General Lamarmora; further several French telegraph officials, who were commissioned by their Government to be present at the laying of the cable, in particular the well-known engineer Delamarche.

Already on the passage to the island of Sardinia, which was favored by gloriously calm weather, the party discussed the methods which should be adopted in laying the cable, in order to avoid the failure of previous attempts. Messrs. Newall and Liddell declared that in laying their wire to the Crimea they had found it best to proceed quickly, and let the cable run out without check, when it would sink slowly to the bottom without any strain. They had indeed for precaution's sake provided a powerful brake-wheel, to regulate the speed of the cable, but that would hardly be necessary if the ship was going fast. This theory of Mr. Liddell was strongly opposed by M. Delamarche, who had been present at the unfortunate attempts of Mr. Brett, and had now adopted the theory that the cable must perforce assume the form of a catenary curve in deep water, and under any circumstances break.

I had originally intended to abstain from interfering in the mechanical part of the proceedings, but it appeared to me so utterly impossible to lay a heavy cable, having a weight in water of at least 4 lbs. per yard, at a depth of more than 1,500 fathoms (as was the case between Sardinia and Bona), in the manner intended by Messrs. Newall and Liddell, that I spoke very earnestly against the proposal. On the other hand I could not share the fears of M. Delamarche, and there ensued a warm discussion between Mr. Liddell, M. Delamarche, and myself, in which I expounded the theory, which was subsequently universally adopted. It consists in holding back the cable by brake-apparatus with a force which corresponds to the weight of a piece of cable in water reaching perpendicularly to the bottom. With a uniform motion of the ship the cable then sinks in a straight line, the inclination of which depends on the ship's speed and the velocity of subsidence of a horizontal piece of cable in the water. If the sinking portion of the cable is not perfectly balanced by the force of the brake, a sliding down of the cable takes place at the same time on the inclined plane which it itself forms; it is therefore possible to regulate by the brake the extra amount of cable that is required to lay the cable without strain over the unevenness of the bottom.

This simple theory met with the universal approval of the company. Mr. Newall too came over at last to my view, and requested me to assist him in the preparations for laying the cable in accordance with my theory. It was, however, difficult to do this on the spur of the moment. The brake, which we found on arriving at Bona on the cable-ship that already awaited us, proved much too weak for balancing the weight of the cable at great depths. Moreover the steam power of the ship was too small to overcome the great force with which the cable would endeavor to slide down the inclined plane. Finally there was no contrivance for measuring this force, and for determining accordingly the amount of the brake action required. I first had a simple dynamometer constructed by the carpenter, which rendered it possible to ascertain the extent of the actual strain on the cable while it is paid out by the amount of flexion of a length of the cable stretched over two rollers, between which a third weighted roller rides on the cable. Furthermore I had the brake wheel strengthened as far as possible, and furnished with strong water boxes. Lastly I caused the captain of the war ship to pass a tow rope from his vessel to the bows of the cable-ship, in order to obtain the requisite force for overcoming the backward drag exerted by the cable.

Thus barely provided, we began in the evening the laying of the cable from Bona. As long as the water was shallow all went well, and my precautions were soon deemed superfluous. After a few hours, when we got into much deeper water, it appeared however that the attainable brake force was not sufficient. We paid out too much cable, and when morning dawned had already used more than a third of the cable, although a fifth of the distance had not been traversed. It was still just possible to reach with the cable-end a shallow spot near the island of Sardinia, if the cable could from now be paid out without any excess whatever. At the request of Mr. Newall I undertook to try this, on condition that the management was entirely left to me. I now loaded the brake with all the weights which were to be found on the ship. Even filled water tubs from the galley were requisitioned. At last the load sufficed, without the brake giving way. We now laid according to the statement of the measurements without "slack," i. e. without using more cable than exactly answered to the length of the sea-bottom. The cable was always pretty near the breaking point, as was proved by the fact that frequently one of the thick sheathing wires snapped, whereby the cable ran considerable risk. But by the adoption of prompt measures a fraction of the cable was averted, and when the sun set, and the cable end in the ship was almost reached, my dynamometer luckily indicated shallow water, and we were at the goal.

The joy was general and intense, and even Mr. Liddell congratulated me on the success achieved.

This was the first cable which was successfully laid in deep water, i. e. at a depth of more than 1,000 fathoms.

The theory of cable laying expounded on the above occasion I only made public in the year 1874 through the medium of a paper entitled "Contributions to the theory of laying and testing submarine telegraph cables" submitted to the Berlin Academy of Sciences. I have preserved among my papers the copy of a letter, in which on my return I explained my theory to the before-mentioned Mr. Gordon, partner in the firm of Newall & Company. I shall insert this letter here, as it forms the first detailed communication on my theory of cable laying:

Berlin, 26th September, 1857.

Dear Gordon: Returning yesterday from my journey I found your letter of the 17th.

First I will give you some particulars from the report made by Engineer Viechelmann, who has to-day returned from Bona.

There is no doubt that wire No. 1 is injured, and that the injury lies in the neighborhood of the African coast, and consists in the wire being in conducting connection with the water. It is not improbable that the defect exists where the shore end is joined to the thinner cable. It has not been possible to determine the precise place, as it is uncertain how much resistance the connection has between the conductor and the water. The place can however lie no farther than four German miles (19 English) from the land, but is probably much nearer.

Through the amount of the charge and by determinations of the resistance in the metallic circuit according to the accompanying sketch (Fig. 1) the situation of the fault may be more precisely determined, if you will make the attempt to take up the wire again from Bona. *m* and *n* are the two coils of a differential galvanometer, and *w* a rheostat. By its means resistance is interposed, until the currents through the two coils *m* and *n* are of equal strength and the needle stands at zero. Then the fault *f* lies midway, and the distance from the coast can be calculated.

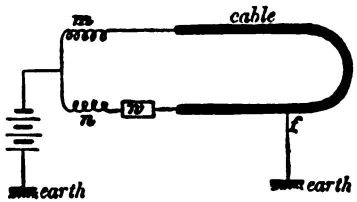

Fig. 1.

With well-insulated wires this can be done with perfect exactitude, with badly insulated ones, such as the Bona cable, at any rate approximately correctly. Mr. Viechelmann has left the apparatus in the custom-house of Marseilles at your disposal. In the telegraph office there lies a letter from Viechelmann to Newall, in which the authority for its delivery is contained.

As regards the cable theory the following is my view:

If *A B* (Fig. 2) represents a flexible piece of cable, which is attached to the sky by a weightless wire *B C*, the cable will fall to the ground, without being able to deviate from the straight line in the suspended part, as at every point it falls with equal velocity. *m n*, *o p* are of equal length. Every point falls with equal velocity, and the new connecting line *n p* must again be a straight one. The active force pulling upon the wire $B\ C$ during the fall is $K = Q \,.\, \sin a$, if Q is the weight of the suspended cable in the water, or the weight of a piece of cable $B\ D$ hanging vertically downwards, since $A\ B \,.\, \sin a = B\ D$.

---

[*] Selected from "Personal Recollections of Werner Von Siemens," recently published in America by D. Appleton & Company, New York, 416 pp., 12mo, uncut edges, wide margin, photogravure portrait.

If the force K is less than is necessary for equilibrium, the cable slides back towards A, and the terminal velocity is reached when the friction water is equal to the lacking force If on the contrary K is greater than necessary, the cable acquires a velocity towards B, consequently the loss, i. e. the difference of the lengths $A\ B$ and $A\ D$ is picked up again, and the cable places itself in a straight line, thus without loss, on the ground. The angle a is accordingly quite independent of the amount of the force K. It simply indicates the proportion of the velocity of sinking to the progressive motion of the ship. For if the cable end B instead of being attached to the weightless wire $B\ C$ is carried over a pulley, and the pulley moves with the ship from B to E, whilst the cable falls the distance $m\ n$, and finally if the cable is kept back with the force K there is no change at all in the conditions of equilibrium. If the brake, which detains the cable, is so applied that equilibrium is just attained, thus $K = Q \,.\, \sin a$, the cable has no axial velocity whatever; it falls perpendicularly, and there is the loss corresponding to the angle. If K is greater, the cable is laid with little or no loss, if K is smaller, the loss may be very great. The quicker in the latter case the motion of the ship, the longer does $A\ B$ become, the greater consequently the friction in the water and the smaller the loss. If on the other hand the force K becomes greater than is necessary for equilibrium, the loss can easily be made up, and the cable then forms a catenary curve. If the transitions are rapid, the whole velocity which the cable has acquired after applying the brake on disturbance of the equilibrium acts in the direction $A\ B$, and tends to strain the cable. When one considers the great mass of the suspended cable, it is clear that these axial velocities of the cable may easily cause a fracture. The only safe guide is the proportion of the ship's velocity to the velocity of the cable. Moreover the ocean currents must be taken into account, especially if they flow in various directions. If the current is everywhere equable, and extends to the bed of the sea, it only produces an additional expenditure of cable. With equilibrium of the force K the cable settles down in the diagonal of the parallelopiped, instead of in the diagonal of the parallelogram, and the cable length bears the same proportion to the distance traversed as the diagonal of the parallelopiped, whose sides are the ship's motion, the depth of water, and the simultaneous velocity of current, bears to the ship's motion. Very violent action on a tightly laid cable may however be exerted by variable currents, as the cable has then to resist the pressure of the water in the form of the catenary curve. Lastly the rising and falling, as well as the lateral movements of the ship, form forces of importance, threatening the fracture of the cable, unless the uncoiling apparatus is very light, or a compensation can be effected whereby the cable may be lengthened or shortened behind the brake, so that no acceleration of the mass takes place. The mechanism which I propose for determining and regulating the tractive force exerted on the cable is easily calculated as under. (Fig. 3).

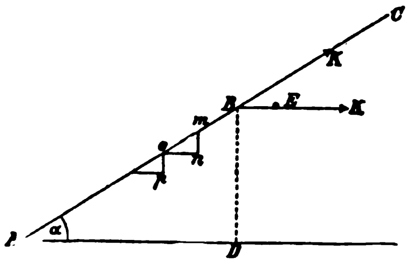

Fig. 2.

$$K \,.\, \sin \alpha = \frac{Q}{2}\,;\quad K = \frac{Q}{2 \sin \alpha}$$

$$\sin \alpha = \frac{h}{ab} = \frac{h}{\sqrt{\frac{e^2}{4} + h^2}}$$

$$K = \frac{Q}{2h} \cdot \sqrt{\frac{e^2}{4} + h^2}.$$

I have asked Löffler to calculate a table in accordance with this formula, of which however I am not yet in possession, as L. is still in Cologne. e was, as you state, 25 feet, i. e. 8·42 metres. The weight Q was 160 kilograms, according to the statement of Newall's people, who weighed it. You seem in your approximative formula to have taken pounds instead, your values are therefore only about half those I have in my memory. The apparatus was constructed of wood the evening before the laying. Previously Mr. Liddel seemed not to be in favor of it, and I did not wish to obtrude myself after having made my proposal. In the first night the frame had become warped through the wet, and the place where the height was measured was about 2 feet lower than the other. A trustworthy measurement with an apparatus so crudely and hurriedly made and calculated is therefore out of the question.

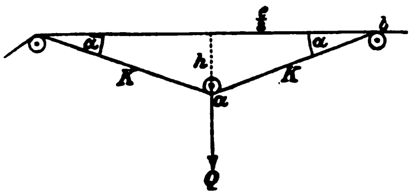

Fig. 3.

That soon after the commencement of the laying much cable was wasted was clear. I therefore at once proposed a stronger loading of the brake, but could not have my way. Undoubtedly there were moments when the cable line was almost straight, although in the ordinary course there was a depression of from 4 to 5 inches, and *one* such moment might have sufficed to break the cable. The brake was also too weak, and I was always in mortal terror lest, with the load of at least 5 hundredweight, which subsequently, when Newall left the matter in my hands, was applied, it should give way. As the cable would have been irrecoverably lost if the brake had given way, it certainly required a prodigious resolution to justify loading it in this manner. It is certain that we strained the cable too severely on the following day. We certainly laid it without any loss whatever, and perhaps already had some catenary curve force in the cable. This was owing to the circumstance that nobody knew how fast the vessel was going. Newall and Liddell thought we were not making 5 knots an hour, whereas in fact we had made 7½. As the cable ran off with the velocity of 7½ knots, I could only conclude that the waste was still too great for reaching shallow water, was obliged therefore to continue the loading. Thus there were moments when the loading reached quite 6 tons, and the fluctuations were even greater.

That there was no regular log in the ship was a serious misfortune, and might easily have had for its consequence the loss of the cable. The greatest danger in cable laying always consists in the snapping of single wires. That under the circumstances we came off as we did is a real marvel. I should not advise attempting a cable laying in deep water without having previously subjected the wire in its whole length to a maximum strain, never to be exceeded in the actual laying.

I have communicated a plan to Newall how this is very easily to be done. Then faulty weldings will be disclosed by rupture, and one may feel pretty safe afterwards. Furthermore a dynamometer of solid iron must be constructed with an accurate scale, and in such a way that with the maximum loading there still remains a deflection of at least one foot. It is better to make use of a well-made spring than a weight, so that the fluctuations of the apparatus may be as small as possible. It would also be very advisable to carry the wire behind the brake over two fixed and one movable pulleys, the latter being pulled down by a weight, cr still better by a very strong spiral spring. The up and down movements of the ship are thereby rendered innocuous.

28th.

As Löffler has not yet returned, I can communicate to you nothing definite in regard to the calculated forces. You are quite right that the assumed forces are not justified by the depths alone. I believe we may go to half the depth for which a cable can support itself with tolerable safety and to a third with great safety. Up to a fifth of the depth 5 to 10 per cent., to a third 10 to 15 per cent. slack may give sufficient safety, if the weather is favorable. At greater depths the loss must be considerably more. Newall's plan of retarding the sinking of the cable by shields is wrong in principle. The cable must sink as quickly as possible on account of the currents. With moderate depths it is more advantageous to take back the slack by somewhat greater loading of the brake. If the depth is greater than one-third to one-half of the minimum strength of the cable, the sliding back of the cable must be slackened as far as possible by disks attached at right angles to the cable. I believe these are best made of sheet iron. A few large ones are far more effective than many small ones. The attachment can be effected in many ways. One must then proceed as quickly as possible, in order to keep the angle acute. For the measurement of velocity I am now having made an electrical apparatus, which turns a large indicator by the side of the brake. The brake wheel must indicate in the same way, so that at any moment the proportion of the velocity and of the exerted force may be known. The vessel must be well lighted, and the breaking of the wires must especially be kept in view. That the two wire fractures did not entail the loss of the cable was a piece of luck such as seldom occurs. Altogether I think you have all reason to be satisfied with the result. I do not consider it difficult to recover the cable end. I likewise consider the repairing of the fourth injured wire feasible, if it is of importance to you. This granted, you have bought the experience and a right theory of laying cheap enough. If you choose to avail yourself of my proposals, you will in future be able to undertake a laying in perfect peace of mind and soon recoup yourself for past losses. With your new brake you should however make the experiment of severing the cable with a maximum strain. Mr. Newall told me before the arrival of the Elba that he could fracture the cable with his brake, but although on the day of laying we had lengthened the lever of the brake by a half, and had suspended at least twice as many weights as the lever and iron band could reasonably be supposed to stand, yet we had not reached such a force by a long way, apart from the great forces which were exerted during fluctuations and in the first mishap. With my own experiments I have unfortunately not succeeded much better than in England. I see however that one can certainly signal better in a metallic than in a semi-metallic circuit, and that it is impossible with long lines to signal through more than a single wire. The future belongs therefore to the metallic circuit, and the patent will be remunerative. I see further that our present construction of the induction telegraph acts remarkably well and accurately, and that several submarine translation stations may at pleasure be set up with absolute certainty, that thus e. g. there may be direct communication between England and India. Your apparatus for Malta-Corfu are despatched to-day. I am quite sure that they will do their work well. According to my present experience the inductors might have been smaller and therefore cheaper, but it is better to err on the safe side. Such fine and solid apparatus have never before been turned out in our workshops. The contacts have given the greatest trouble. Platinum burns too quickly with strong primary currents, we were therefore obliged to use everywhere an alloy of gold and platinum, which with thick pieces has its difficulties. Perhaps you will get along with half the inductors on the Malta line (one coil). You will thereby effect a considerable saving, as the great quantity of silk covered wire is expensive.

I beg you to let me know in good time when and where you wish to have the mechanician, and whether you think one enough. I think you should have plenty of intelligent assistants at your disposal, for any error may be very dangerous even with the best preparation.

I send this letter direct to Birkenhead, where I imagine you still to be, and where William intended to visit you; may I ask you to let William have a look at it?

Would it not be better to defer your Malta line to the winter, when you can more certainly reckon on calm weather? October is said to be a very dangerous month there, and the atmosphere does not become quieter before December.

With sincere regards.

W. SIEMENS.

(To be Continued.

It is reported that Donald Murray of Sydney, New South Wales, has devised a system for setting type by telegraph. Mr. Murray claims that it is possible by his invention to operate at a distance, over a single telegraph wire, a typewriter, a type-setting machine, a piano or any other keyboard instrument.

Boston Notes.

Electricity was impressed into service very generally in Boston for illuminating purposes during the recent Christmas season, and some really wonderful results were attained. Indeed, this city never before looked so brilliant, thanks to electricity and the genius and skill of those who are in the business. Many singularly beautiful displays were made, but the palm was easily carried off by Messrs. Houghton & Dutton, whose mammoth 9-story building, known as the Albion Block, corner Tremont and Beacon streets, was a mass of light radiated from over 1,200 plain and colored incandescent lamps. Being a corner building, two sides of the block were available for the display, which was more than attractive. Long strings of lamps depended from the roof to the sidewalk, while the full name of the firm was wrought in ruby and white lamps. There was also the old legend, "A Merry Christmas," together with crescents and stars of light, while on the parapet of the roof at the corner was an immense American flag wrought in plain and colored lamps. To produce the beautiful effect of the flag fluttering in the breeze there was an ingenious arrangement for cutting out and in, in quick succession, the vertical rows of lamps, producing a most charming and realistic effect. The cut-out was operated by an electric motor, so that the action of the whole was very accurate and very pleasing. The streets in the immediate neighborhood were impassable for several nights in consequence of the crowds. At another store there was a large windmill, the sails of which, studded all over with colored incandescent lamps, were kept constantly revolving by an electric motor. The mill structure was as if covered with snow, the surroundings outside being treated in like manner. The windows in the mill were lighted up from within, the glass in the windows changing its colors continually, including all the tints of the spectrum. There was also a large model of the Ferris wheel, kept in motion by a motor peacocks in gorgeous plumage, and dragons with fiery tongues, forked tails and wings of terrible mien, in which small electric lamps of every conceivable color played an important part. The local Edison Light Company did a good deal of the work, they having in their employ quite a number of experts who have developed very fine tastes in the art of illumination.

The Edison Illuminating Company is constantly adding to its already big business, yet finds that it is now able, with its three finely equipped central stations, to take care of all that comes along. At the present, from these three stations the company is furnishing current for 85,000 incandescent lamps, 7,000 arc lights, and 3,700 H. P. of current wherewith to run 1,300 motors. The foregoing is a showing that compares favorably with most other large companies.

The Massachusetts Electric Light and Power Company, recently organized in Fitchburg, Mass., will construct a large central station on a fine water privilege five miles from Fitchburg, and intends to furnish current for operating the local railroads as well as for lighting the whole of the city and running motor circuits.

Notwithstanding the fact that lamp litigation continues and the General Electric Company still shows a disposition to keep along with its suicidal and antagonizing policy, there is an equally determined disposition to harass the Trust still more, for it is reported that there are at the present moment several new types of incandescent lamps invented in or near Boston about ready for the market, which means that the process of depleting the already nearly exhausted exchequer or coffer—we had nearly said coffin—of the General Electric Company will continue for some time to come—so long, indeed, as the Edison patents shall last. Of course the lawyers don't object to the appearance of new lamps, they bring grist to the legal mill.

It's a hopeful and healthful sign that the electrical business is not by any means at a standstill when we see the opening of new places of business by well known electrical firms. The prosperous Perkins Switch Company of Hartford, Conn., has just located a representative at 620 Atlantic avenue, Boston, who will carry a full line of the Perkins specialties. Mr. F. B. Smith, who will fill this important position, is a gentleman well known in electrical circles, and we bespeak for him a pleasant and profitable welcome into the electrical business of this part of the country. The Perkins electrical goods recommend themselves every time, and have a ready sale everywhere.

The Simplex Electrical Company, makers of the high grade and universally known "Simplex" wires and cables, has removed its chief offices from 620 Atlantic avenue to Cornhill, Boston. Mr. James Mason, chief manager, has just had a severe attack of la grippe, but is again so far recovered as to be able to take the general oversight of the extensive business in wires and cables his company does.

General News.

What is Going on in the Electrical World.

Knoxville, Tenn.—J. F. Scott has applied to council for a franchise for an electric railway on Central avenue and other streets.

Altoona, Pa.—The power house of the Altoona and Logan Valley Electric Street Car Company was damaged $25,000 by fire on the 21st ult.

Syracuse, N. Y.—T. D. Davis, of this city, is the author of a plan for towing canal boats by a motor running on the towpath and getting its power from an overhead trolley.

Parkersburg, W. Va.—The franchise of the Park City Street Railway has been purchased by the American Construction Company of Boston. The purchase includes the track already laid.

Muncie, Ind.—J. N. Cropper having given bond in $20,000 has been appointed receiver of the Muncie Electrical Works. This step was necessary to bring about a dissolution of partnership.

Port Jervis, N.Y.—The Port Jervis Suburban Street Railway Company have been granted a franchise for their proposed line in this place. The applicants are the same men who are now building the Middletown electric railway.

Omaha, Neb.—The mayor having objected to the Thomson-Houston electric lighting bills, believing that the company had failed to supply a 2,000 candle power light, the city council has voted in favor of paying the bills over his veto.

Cleveland, Ohio.—R. D. Geib, of this city, has invented a device he calls a trolley finder which is designed to return the trolley to the wire when it has slipped off. It has been tested and worked with complete success.

Trenton, N. J.—The New Jersey Railway Company, of which Joseph H. Reale, of Bloomfield, seems to be the active head, is planning to build an electric railway from New York to Philadelphia, via Trenton, with spurs to all the side towns.

Richmond, Va.—In printing an item showing the successful operations of an electric freight-railroad in Maine, the *States* remarks that "many such roads will be built in Virginia within the next few years, the first of which, let us hope, is the proposed electric line to Petersburg."

Medina, N. Y.—A single rail railway is projected between Batavia and Oak Orchard, via either Albion or Medina, to practically test Capt. Lina Beecher's new invention. The invention has been tried on a short test line and has been found, it is said, to work in a perfectly satisfactory manner.

Ellenville, N. Y.—It is believed here that an electric railway running down the Rondout valley and connecting a number of villages would be a boom to the locality. The subject is receiving increasing attention. There is a 75 foot waterfall in the vicinity that could be utilized in generating electrical power.

Providence, R. I.—The Interstate Railroad Company, a corporation operating an electric railway between Providence and Pawtucket, has been placed in the hands of Cornelius N. Sweetland as receiver. This it is believed will lead to the absorption of the road by the United Traction Company.

New York.—The Waddell-Entz Company has called the attention of the Metropolitan Traction Company to their storage battery system now in operation on the Second Avenue Railroad line as meeting the requirements specified in the offer of the $50,000 prize for a motive power for street railways dispensing with overhead wires.

Meriden, Conn.—The city authorities, possessed with the idea that they were paying more for their electric light than it would cost if the city did its own lighting, appointed a committee to inquire into the matter. After due investigation, the committee reached the conclusion that they were getting light at a reasonable price, and a three years' contract with the local company was the result.

Fall River, Mass.—At a meeting of the men interested in the proposed electric railway between this city and Stone Bridge, Tiverton, a company was organized by the election of the following officers: President, Daniel T. Church; directors: Daniel T. Church, of Tiverton; Nathaniel B. Church, of Tiverton: Weaver Osborn, of Fall River; George W. Slade, of Fall River; M. G. B. Swift, of Fall River; Frank Stevens, of Swansey, and Robert S. Goff, of Fall River. Work on the road will begin in the spring.

Cincinnati.—The Cincinnati Gas Light and Coke Company have called a meeting of stockholders on the 22d inst. for the purpose of voting on an increase of stock from $7,500,000 to $8,100,000 for the purpose, it is intimated, of enlarging the business by the addition of an electrical department, to be accomplished through the acquisition of the plant of the Cincinnati Electric Company by an exchange of gas stock for an equal volume—par value—of Cincinnati Electric Light stock.

Baltimore, Md.—The company which proposes to build an electric railway between this city and Washington, to be known as the Baltimore and Washington Turnpike and Tramway Company, has been reorganized with the following board of directors: David M. Newbold, president; Robert T. Carswell, Charles B. Calvert, John J. Dobler, William L. Elkins, Peter B. Widener, Thomas Delan, T. Edward Hambleton and Howard Munnikhuysen.

St. Louis, Mo.—The notice of the assignment of the Municipal Electric Light Company to the Edison Company has been filed with the Register. The notice states that October 14, 1893, the entire business of the first named company was assigned to the Edison Company, including two contracts for lighting the streets of the city of St. Louis for ten years from January 1, 1893.—A move is on for the organization by the capitalists of St. Louis of a new electric light company, to be known as the Consumers' Company, for the purpose of fighting the trust.

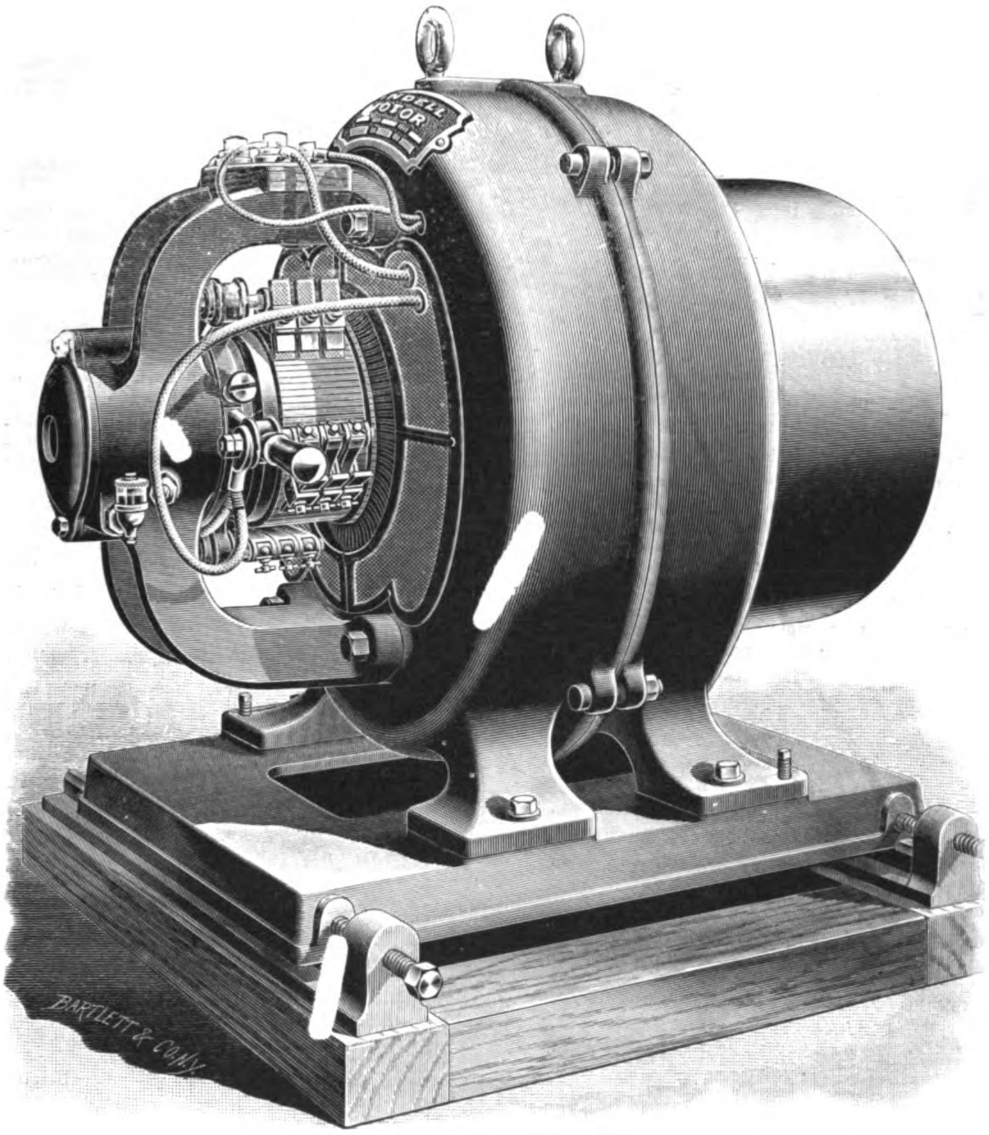
Washington, D. C.—The promoters of the Washington and Marlboro electric road have presented their scheme to the Commissioners. The company proposing to build the line already has a charter from the State of Maryland to build the road from Marlboro to the District line on the other side of the Eastern Branch of the Potomac, and is now making an effort to secure a charter so that it can build its own bridge across the Eastern Branch and to enable it to enter the city in the neighborhood of the Centre Market, its objective point.

Indianapolis, Ind.—The Board of Commissioners of Marion County, Ind., will receive sealed proposals at the County Auditor's office in Indianapolis until January 15, 1894, at 2 o'clock p. m., for an electric lighting plant for the Marion County court house and new jail building, according to plans and specifications for the same now on file in the Auditor's office of said county. Each bidder must file with his bid a good and sufficient bond in amount equal at least to the amount of the bid which it accompanies. The board reserves the right to reject any and all bids.—The scheme to build an electric road from Indianapolis to Broad Ripple, some eight miles beyond the corporation limits, has fallen through.

St. Paul, Minn.—The *Globe* says: "The recent incorporation of the Williams Manufacturing Company is the first step in the organization of a mammoth co-operation concern in St. Paul to manufacture the Kent telegraph typewriter; also electric motors and aluminum wares. The capital stock is fixed at $10,000,000, but it is the intention to begin building the factory as soon as $100,000 is subscribed and paid in. The location of the factory is not settled upon, and while it is the present intention to place it in St. Paul, affairs may turn so that it will go to St. Paul Park. One thing is settled definitely, and that is that it will be a co-operative institution. It is intended that every member of the large force of workmen shall be a shareholder and a sharer of the profits."

New Orleans.—The council ordinance authorizing the St. Charles Street Railroad Company to use electricity as a motive power has been referred to a sub-committee.

Santa Fe, N. M.—Arrangements for enlarging the plant of the Santa Fe Electric Light Company are now under way. At a recent meeting of the stockholders the following officers were elected: G. W. Knaebel, president; Grant Rivenburg, manager and secretary; J. G. Schumann, treasurer.



BARTLETT & CO. N.Y.

THE LUNDELL DYNAMO.

Middletown, Conn.—The Schuyler Electric Company's factory here is entirely closed. It provided work for 600 operatives.

Sandusky, Ohio.—Interest in the projected electric road between Sandusky and Norwalk has been revived, and there is a plan forming for applying the $30,000 that was formerly voted by this city for the Sandusky, Ashland and Southern road and using it to assist in building the new line.

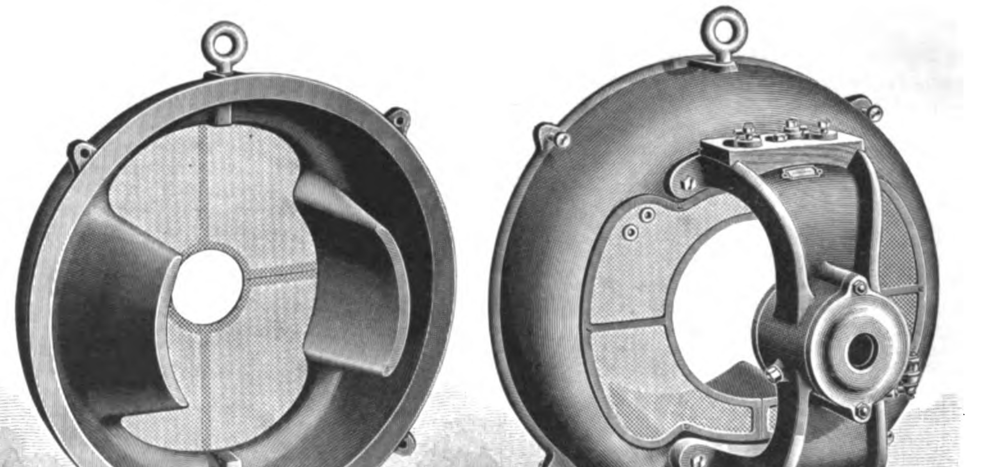
Description of the Lundell Type of Direct-Current Dynamos and Motors.

The Lundell type of direct-current dynamos and motors is the ideal of simplicity and compactness. In fact, this type is so simple that an elaborate description of the different parts is entirely unnecessary. The chief characteristics are embodied in the novel construction of the field magnet, whereby a single energizing coil magnetizes all the pole pieces and a strong protecting shell for the windings of both field and armature forms the magnetic circuit.

The arrangement of the field magnet and its energizing coil is clearly illustrated in our engravings.

It will be noted that the two field magnet halves when bolted together form a shell which completely protects the armature, the whole of the shell being utilized in the magnetic circuit. These field magnet halves are so designed that they are readily withdrawn from the mould in casting. The cross section of the shell equals the cross section of the base of the pole pieces, so that no choking of the lines of force can occur at any point. Cast steel is employed for all these dynamos and motors. The single energizing coil not only reduces the construction of the machine to the simplest point, but by having only two terminals it is especially adapted to be placed in the hands of inexperienced users, as it avoids any possible mistake in connecting up or any bother or delay in examination when such becomes necessary. Another feature of the design is that the pole pieces are magnetized directly, and the resistance of the magnetic circuit reduced to a minimum, whereby a considerable economy in the ampere turns of the energizing coil is effected.

The armature adopted for these machines is of a modern Pacinotti form. This type of armature has in the past been subject to unfavorable criticism on account of the resultant heating of the pole pieces, but it is now pretty well recognized that this heating was not due to the Pacinotti ring itself, but to the lack of knowledge with regard to its proper design. A little reasoning will show that when the ratio of the distance between the teeth and the magnetic gap is too small a concentration of the lines of force will take place so that the pole pieces will be swept over alternately by sections of the highly concentrated lines of force and by practically inert material. The result is that Foucault currents must inevitably be set up in the pole pieces and cause the heating which has been noted in the past. By so proportioning the teeth, however, that the lines of force emanating from the pole pieces are more evenly distributed over their entire surface surrounding the armature, this abrupt demarcation is avoided, with the result that Foucault currents are also avoided in the pole pieces.



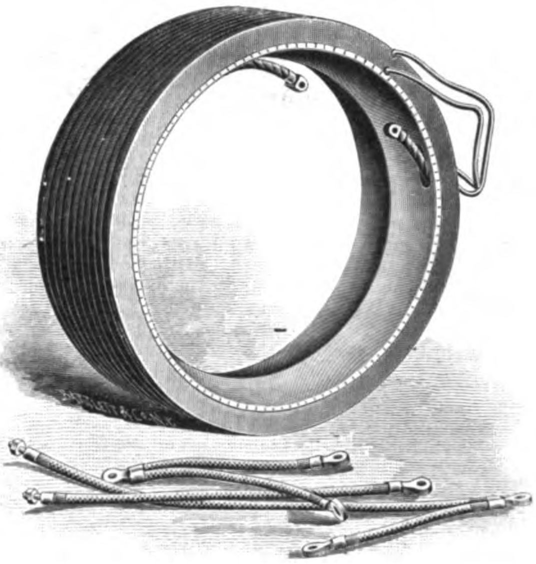
BARTLETT & CO. N.Y.

LUNDELL FIELD MAGNETS.

The result of actual practice with the Lundell machine has shown the soundness of this theory, which is carried into practice by the employment of deep and narrow slots.

Notwithstanding the ironclad nature of the machine, the concentric position of the field coil allows the armature to be withdrawn without disturbing either the field coil or the pole pieces.

The openings around the armature at the ends of the field magnets are, in the larger machines, covered with metal screens to protect the working parts, and to secure at the same time perfect ventilation. The commutator portion of the armature alone projects outside the screen, and is well protected by a strong bracket which carries the out-board bearing. The brushes are arranged diametrically around the commutator and the opposite brushes are in all four-pole machines connected together. They can be raised from the commutator when the machines are not in use.

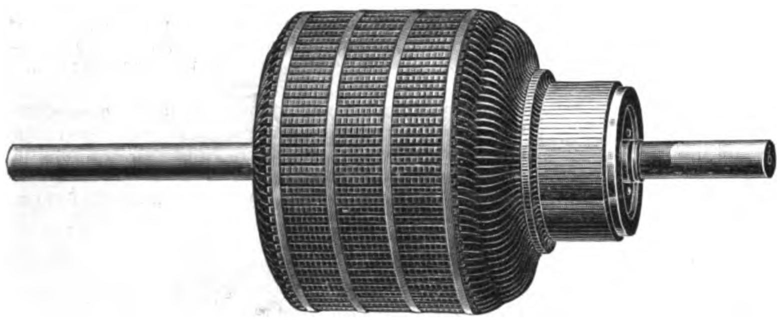


LUNDELL FIELD COIL.

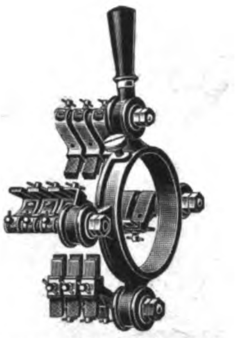
The brushes of the two-pole type have a unique spring arrangement for pressing the carbon brushes against the commutator. The spring has its rear end placed in a curved slot at the end of the brushholder, while its forward end in the shape of a T presses against the carbon which slides in the ways in the brushholder. To remove the carbon, it is merely necessary to press the spring upwards out of the slot, which releases it so that the T can be withdrawn, and the carbon slides out.

The bearings are constructed with mechanical accuracy, are self-oiling and are provided with a vision gauge. The bushings are made of the best material and are so arranged as to be readily removed and renewed when worn out.

Recognizing also the necessity of continuous lubrication, oiling is accomplished by means of a number of rings which encircle the shaft and dip into the reservoir, thus continually feeding fresh oil to the bearing. In order that the attendant may know the exact condition of the oil, a simple oiling device has been added, consisting of an elbow with an oil chamber rising slightly above the normal level of the oil. The vertical arm of this elbow is so arranged that when the visual gauge is half filled the bearing is properly oiled. The glass tube is made so short that by no possible inadvertency can the attendant pour in oil sufficient to flood the bearing and cause the oil to run out at the inner surface of the shaft and so go into the armature.



LUNDELL ARMATURE.

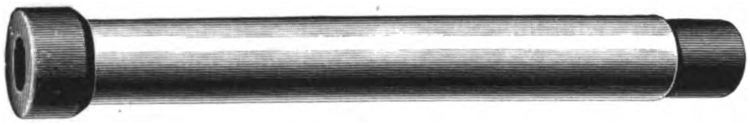


LUNDELL BRUSH-HOLDER.

The Interior Conduit and Insulation Company guarantee that the efficiency of the Lundell dynamos and motors is as high as can be obtained by any first class machine.

This company is also introducing an armored bushing which complies with the requirements of the Underwriters' rules. This bushing has points of superiority over any other kind permitted by the rules.

It is thoroughly "waterproof," "non-combustible," and has superior insulating qualities. The armor gives strength and durability, which neither glass, porcelain nor vulcanized rubber composition possesses. It is more serviceable, requiring a smaller hole in beams and joists than porcelain or glass, and for this reason alone should meet with the approval of architects.



ARMORED BUSHING.

Queen & Company's Tachometers.

Queen & Company, Philadelphia, have a very excellent portable tachometer by means of which the speed of engines, dynamos and motors can be quickly and accurately determined. It is compact, convenient to handle and will indicate revolutions up to 3,000 turns per minute. They also have stationary types for permanent attachment. In the economical operation of a lighting or power plant it is highly necessary to run a dynamo very close to schedule speed, which can only be determined by an instrument such as the above.

An Encouraging Report.

Working full time and full capacity, and behind on their deliveries, is the gratifying report furnished by the Clayton Air Compressor Works, of 43 Dey street, New York, as to their shops in Brooklyn.

In the prevailing business depression this speaks volumes for the excellence of the Air Compressors built by this company. They have recently taken out several valuable patents on a new triple compound high pressure air or gas compressor, used largely by manufacturers of carbonic acid gas.

The Ball Engine Company.

The following sales of Ball Engines were made by Mr. F. R. Chinnock during the last few weeks of his connection with the Ball Engine Company:

J. M. Iver Company, Danbury, Conn., 1 engine.
Ridgewood Electric Light and Power Company, Ridgewood, N. J., 1 boiler.
Brooklyn Navy Yard, one 100 h. p. heavy duty engine, for running saw mill.
General Electric Company, for Hot Springs, Va., increase, 2 engines, 1 boiler.
Imperial Hotel, New York City, one 150 h. p. engine.
Messrs. Schwarzenbach, Huber & Company, Union Hill, N. J., 1 boiler.
For export to Cuba, 3 engines.
Big Four Railroad Company, Indianapolis, Ind., complete steam plant, including 2 engines and 3 boilers.
John Goode's Rope, Cordage and Machine Company, Ravenswood, L. I., one 600 h. p. cross compound engine.

The Mather Electric Company.

Messrs. G. H. Angier & Company have succeeded Claflin & Kimball, incorporated, as New England agents of the Mather Electric Company, with offices at No. 116 Bedford street, Boston.

During the last two years Mr. Angier has had charge of the selling department of the Mather Electric Company and its various branch offices located throughout the United States. He has resigned this position, however, and will hereafter be the active manager of the new firm.

The Mather dynamo has been on the market for the past six years, and is in operation in over 1,000 of the largest mills in the country. This machine is particularly adapted for use in large buildings and manufacturing establishments.

Mr. C. A. Bowditch, who has been a very popular and successful attache of the Thomson-Houston and General Electric Companies for the last six years, has resigned his position with the General Electric Company and will have charge of the motor department of the Mather Electric Company, being associated with G. H. Angier & Company.

A Holiday Souvenir.

We have received a souvenir paper weight from the Electric Railway Equipment Company, of Cincinnati, in the form of a miniature trolley car, which was produced at their foundry, and which they are presenting to their friends with the compliments of the season.

INCORPORATIONS.

The Conduit Construction Company, New York City—to construct electrical conduits. Capital stock, $25,000. Promoters: Thos. C. Buck, Chas. W. Keep, Julien L. Myers, New York.

The Mechanics' General Manufacturing Company, St. Paul, Minn.—to manufacture electric motors, hardware and aluminum wares, novelties, machinery tools, materials or goods of any kind. Capital stock, $10,000,000. Promoters: Darwin H. Kent, St. Paul Park; A. A. Price, F. M. Johnson, P. L. Uttly, C. J. Backus, St. Paul.

The Pontiac Standard Lighting Company, Detroit, Mich.—to produce, manufacture and sell electricity for light and power in Pontiac, Mich. Capital stock, $30,000. Promoters: Geo. E. Fisher, O. D. Chase, Detroit; Geo. H. Foster, Pontiac, Mich.

Wallace Electric Company, at Chicago. Capital stock, $2,000. Incorporators: William J. Candish, William V. R. Lansigh and Jessie F. Pebbles.

The Stephenson Electric Light Company, Stromsburg, Neb.—to engage in electric lighting, etc. Capital stock, $25,000. Incorporators: J. B. Buckley, P. T. Buckley, J. A. Frawley, G. S. Osborne and Dr. W. A. Post.

The Cutler-Hammer Manufacturing Company, Chicago—to manufacture electrical appliances. Capital stock, $50,000. Incorporators: H. H. Cutler, E. W. Hammer, R. L. Commons.

The Prairie City Electric Company, Prairie du Chien, Wis.—to establish and operate a general electric plant. Capital stock, $5,000. Promoters: W. H. Thompson, A. I. Heiman, S. N. Bresbee.

The Northwestern Telephone and Electric Company, Milwaukee, Wis.—to engage in general telephone and electric business, manufacturing and dealing in appliances, etc. Capital stock, $50.000. Promoters: A. B. Ferdinand, H. C. Dodge, E. V. Spencer.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 19, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

511,017. Electric Railway Switch and Crossing. William W. Hendrix, Bowling Green, Ky. Filed Aug. 5, 1892. Renewed Nov. 22, 1893.
511,018. Electric Railway Trolley. William W. Hendrix, Bowling Green, Ky. Filed Aug. 5, 1892. Renewed Nov. 22, 1893.
511,019. Electric Railway Trolley. William W. Hendrix, Bowling Green, Ky. Filed Oct. 7, 1892. Renewed Nov. 22, 1893.
511,131. Electric Railway Signal. Jose Ortega y Espinosa, Mexico, Mexico. Filed Oct. 26, 1891.
511,173. Electrically Operated Railway Switch. Chas. A. Stone, Newton, and Edwin S. Webster, Boston, Mass. Filed Aug. 30, 1892.
511,254. Closed Conduit Electric Railway. William S. Smith, Berkeley, Cal. Filed Feb. 29, 1892.

ELECTRIC LIGHTS AND APPLIANCES.

511,049. Electric Arc Lamp. August Hormel and George S. Junginger, New York, N. Y. Filed March 24, 1893.
511,229. Electric Lamp. Albert Zobel, Munich, Germany. Filed Feb. 15, 1893.

MOTORS, DYNAMOS, ETC.

510,892. Brush-Holder. John R. Coffman, Detroit, Mich., assignor of one-half to the Eureka Tempered Copper Company, North East, Pa. Filed Dec. 9, 1892.
510,947. Electric Locomotive. Charles F. Winkler, Troy, N. Y., assignor to the United Columbian Electric Company of New Jersey. Filed March 11, 1893.
510,952. Brush-Holder for Dynamo-Electric Machines. Frank E. Averill, Syracuse, N. Y. Filed Feb. 13, 1893.
511,157. Hand Regulator for Electric Motors. William D. Packard, Warren, Ohio. Filed Dec. 8, 1892.
511,196. Electric Motor. Oliver F. Conklin, Dayton, Ohio, assignor to the Dayton Fan and Motor Company, same place. Filed July 5, 1893.
511,214. Brush-Holder for Electric Motors. James J. Robison and Fred. B. Perkins, Toledo, Ohio. Filed Feb. 6, 1893.
511,289. Power Transmitting and Speed Regulating Mechanism. William Cooper and George P. Hampton, Minneapolis, Minn., assignors, by mesne assignments, to the Cooper-Hampton Electric Company, same place. Filed Jan. 27, 1892.

TELEPHONE AND TELEGRAPH APPARATUS.

510,929. System of Telegraphy. Josiah A. Parker, St. Louis, Mo., and Leland L. Summers, Chicago, Ill. Filed July 30, 1892.
511,005. Telegraphic Relay. Edward Weston, Newark, N. J. Filed June 4, 1891.
511,081. Telautograph. Rudolph M. Hunter, Philadelphia, Pa. Filed May 26, 1893.
511,118. Magneto-Telephone. James A. Brown, Moline, Ill. Filed Aug. 16, 1893.
511,172. Telegraphic Transmitter. Mary E. Stinde, Red Bud, Ill., administratrix of Herman F. Stinde, deceased. Filed May 4, 1893.
511,234. Morse Transmitter. Albert F. M. Cornand, Brussels, Belgium, assignor of one-half to W. T. Barnard, New York, N. Y. Filed May 29, 1889.
511,244. Telegraph Relay. Frank P. Medina, San Francisco, Cal. Filed May 4, 1891.
511,276. Two Station Telephone Circuit. Frank A. Pickernell, Newark, N. J. Filed Aug. 7, 1893.

BATTERIES.

511,159. Primary Electric Battery. Edward Poppowitsch, Brooklyn, assignor of one-half to Herman Wustenfield, New York, N. Y. Filed Dec. 28, 1892.

ELECTRIC SWITCHES.

511,187. Electric Regulating Switch. Edward A. Barrer, Watertown, N. Y. Filed June 26, 1893.
511,240. Electric Switch. Jesse L. Hinds, Syracuse, N.Y., assignor to the Electric Engineering and Supply Company, same place. Filed Nov. 27, 1891.

MISCELLANEOUS.

510,889. Temperature Regulator for Electric Heaters. Albert M. Butz, Oak Park, Ill. Filed Dec. 24, 1892.
510,898. Electrical Connector. Frank G. Curtis, New York, N. Y. Filed Feb. 13, 1893.
510,899. Method of Adjusting the Joints of Carbon Electrodes. Elisha B. Cutten, New York, N. Y. Filed March 28, 1893.
510,900. Apparatus for Electrolytically Producing Soda and Chlorine. Elisha B. Cutten, New York, N. Y. Filed March 30, 1893.
510,901. Electrode for Voltaic Cells. Elisha B. Cutten, New York, N. Y. Filed May 1, 1893.
510.902. Electrode for Voltaic Cells. Elisha B. Cutten, New York, N. Y. Filed May 1, 1893.
510,921. Electric Pump. Frank N. Merritt, Duluth, Minn., assignor to the Electric Motor Company, same place. Filed Dec. 2, 1892.
510,932. Electric Elevator. Frank A. Perrett, Brooklyn, N. Y., assignor to the Elektron Manufacturing Company of New York. Filed Nov. 12, 1892.
511,188. Electric Signaling Device for Hose. George L. Barnard, Milwaukee, Wis. Filed Aug. 22, 1892.
511,245. Thermo-Electric Element. Max Mestern, Turin, Italy, assignor to the Thermo-Electric Company of West Virginia. Filed April 9, 1889.
511,259. Rheostat. Franklin A. Weller, Boston, Mass. Filed April 20, 1892.
511,286. Resistance Box. Adelbert O. Benecke, Newark, N. J. Filed Sept. 10, 1892.

To Inventors and Others.

United States and Foreign Patents Procured.

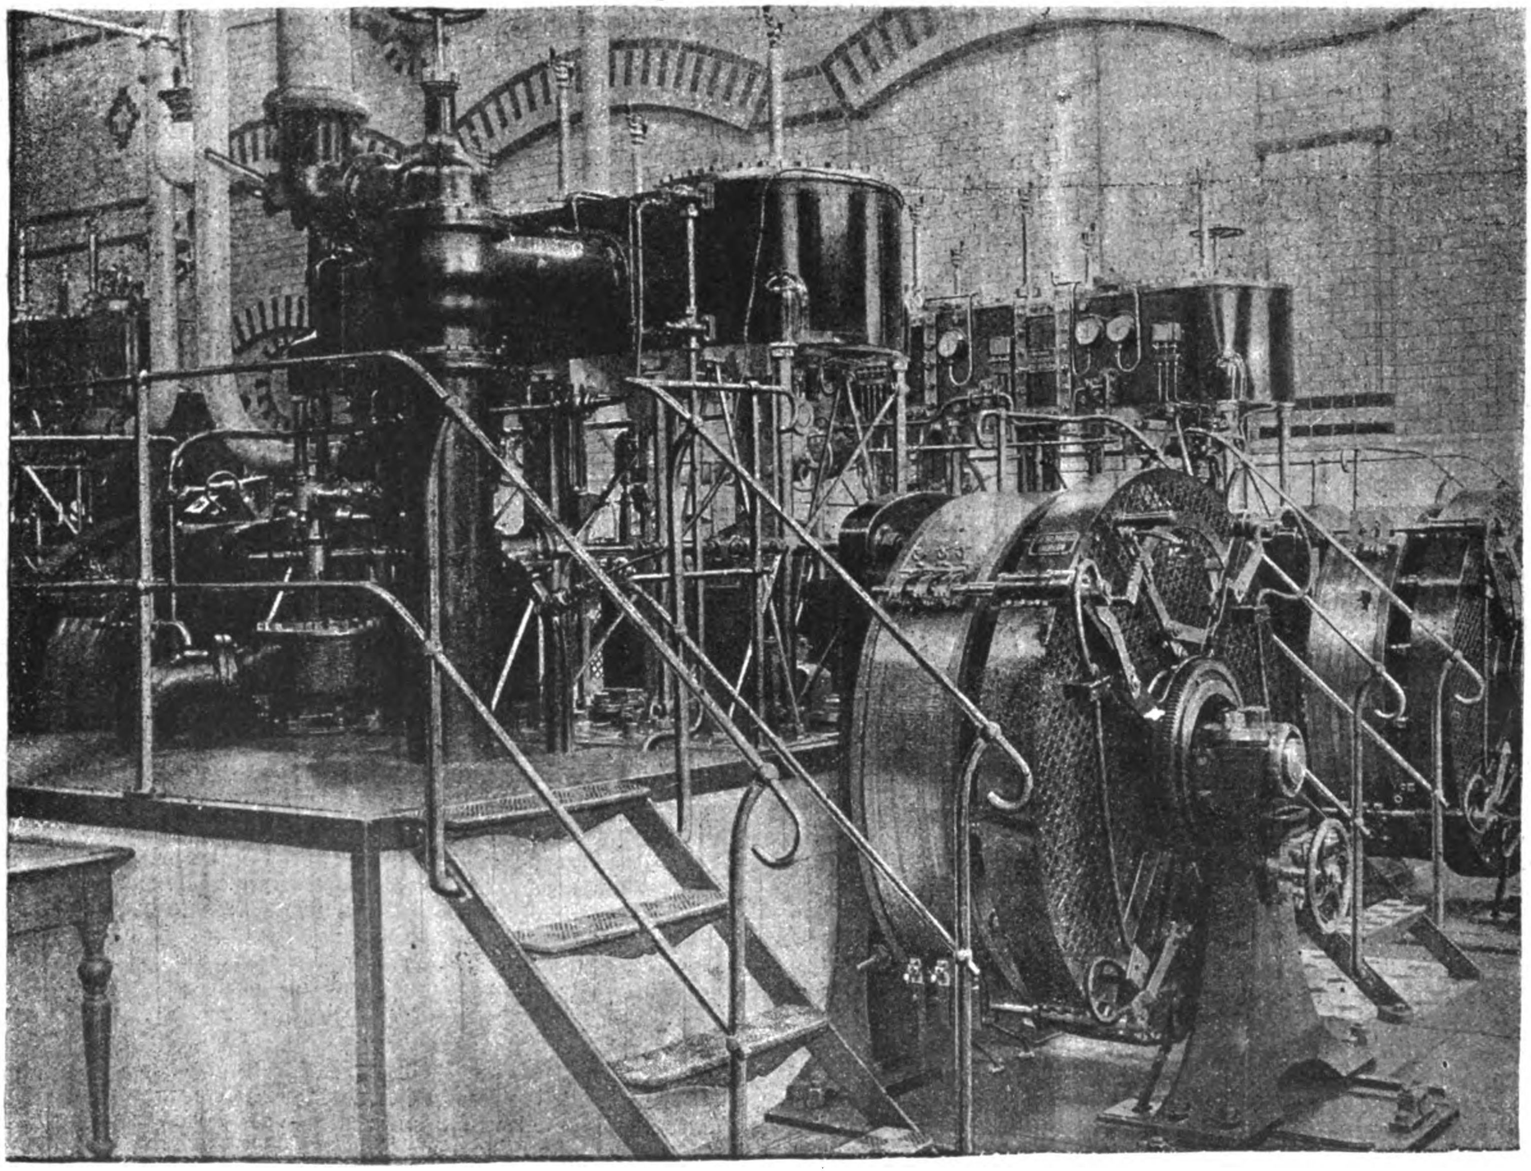
A PATENT DEPARTMENT has been established in connection with the publication office of ELECTRICITY, for the transaction of all business connected with the procuring of patents on inventions and devices of all classes. The object is to furnish inventors and others, at moderate cost, with a reliable, well-equipped and accommodating bureau through which they may be aided in procuring United States and foreign patents and obtain all information necessary to a successful prosecution of their claims.

Immediate attention will be given to inquiries and orders by addressing

T. F. BOURNE,
Manager Patent Department ELECTRICITY,
6 Park Place, New York City.

ELECTRICITY.

VOL. V. NEW YORK. JANUARY 10, 1894. CHICAGO. No. 26



DYNAMO ROOM, KONIGSBERG STATION. (SEE PAGE 306.)

The Five-Wire System at Konigsberg.

The municipal central station at Königsberg is one of only four stations which have adopted the five-wire system of distribution up to the present time. The area covered by this system is approximately a semi-circle whose diameter is about 2½ k. m., and the station is situated 40 metres from the centre of the circle, which is a considerable distance from the centre of distribution. It was for this reason that the five-wire system was decided upon, and the work was designed and installed by Messrs. Naglo Brothers, of Berlin, who proposed to employ dynamos varying from 90 to 160 volts, such as are required for parallel working and charging of accumulators. The accumulator battery had originally been projected by the town of a capacity of 400 lamps of 16 candles each during 10 hours. Such a battery was much too small, and working under these circumstances would have been out of the question. The municipality, accordingly, sanctioned Messrs. Naglo's proposal to increase the capacity of the battery to 1,000 lamps for 10 hours.

It is, however, not only the adoption of the five-wire system which invests the Königsberg Station with special interest, but also the mode of construction of the conducting network. The conditions specified in the tender only prescribed an underground system, leaving to the competitors the choice of details, and Messrs. Naglo Brothers, instead of the customary cables, proposed bare copper strips fastened to porcelain insulators and laid in *Monier* conduits. This mode of construction presents several advantages; in the first place a network of this kind has a high insulating capacity, and even if a leakage should occur through the condensation of moisture on the surface of the insulators, the heat produced by the escaping current would soon decompose the conducting layer of water. Another great advantage is the easy accessibility of the network. This is of special importance when additional conductors have to be laid, through increased consumption.

In the boiler-house there are four tubular boilers, constructed by Dürr, of Ratingen; they are of 134 sq. m. heating surface each, and 12 atmospheres pressure. The engines, coupled direct to the dynamos, have been constructed by F. Schichau, of Elbing; the two larger ones are of 200 horse power, the smaller ones of 100 horse power each. All four are vertical triple-expansion condensing engines, the condensing water being obtained either from a well communicating by a pipe with the river Pregel or from the town supply. All the machines make 200 revolutions per minute. The cylinder diameters of the larger machines are respectively 300, 490, and 750 mm. at a common stroke of 350 mm., while those of the smaller machines are 240, 390, 600 mm. respectively. To either side of the prolonged shaft of the four steam engines a dynamo armature is keyed direct, while the field-magnets are bolted to the engine frames.

The Frontispiece shows part of the machinery room, containing two steam engines together with the dynamos coupled direct to them. The dynamos, as will be seen from the figure, are internal-pole machines, the smaller ones with 4 and the larger ones with 6 poles. The armatures have no special collectors, but the current is taken off from the external circumference of the winding by 4 or 6 groups of three brushes each, the brush-holders being fastened to and movable about a common casting, so that they can, by means of levers fastened to their extremities and connected to a second casting, be simultaneously pressed against or taken off from the armature circumference. The frame carrying the brush-holders can also be turned by means of a hand-wheel, and the position of the brushes altered in this way. The magnet coils of the whole of the 8 dynamos are shunt-wound, and the winding is so arranged that the voltage can be varied between 90 and 160 volts. For the large dynamos an output of 64 kilowatts at 100 horse-power and for the small machines half this output had been guaranteed, which is equivalent to 630 watts per horse-power or 85.6 per cent.

The battery of Tudor accumulators, supplied by the Hagen Accumulator Company, consists of 284 cells of type 24. The capacity of this type of cell at a maximum discharge current of 276 amperes is 920 ampere hours, and rises, at a discharge of 158 amperes, to 1,320 ampere hours. The charging current is 230 amperes, and the battery at present can feed about 1,260 lamps.

The regulation of this battery is effected by automatic cell switches having two sets of connections to the system. One set consists of test wires which are connected to various distributing centres, and the other connection is made to a point of constant potential, and the regulators preserve a balance in the pressures between these points.

The discharge levers of the 5 cell switches are operated automatically. For this purpose 5 switches and relays are provided, the relay leading to the middle cell switch being polarized. The lever can also be operated at will, by making contact through push buttons. Two levers are provided for each cell switch, one for right hand, the other for left hand motion. The charging levers of the cell switches are operated by hand, according to the indications of a voltmeter giving the E. M. F. of the first cell to be switched off. These cell switches are manufactured by the Hagen Accumulator Company.

The current from each dynamo after passing through an ampere meter, fuse and automatic cut-out is led to a switch from which it can be sent either to a bus bar or the charging lever of a cell switch. The discharge levers of the cell switches are connected through ampere meters, cut-outs, etc., to the same bus bars that are connected to the dynamos, from which the feeders are taken off. Relays which operate at a definite voltage are employed to prevent the dynamos from being put into circuit before reaching the proper E. M. F.

The underground system has eight distributing points, to each of which five feeders are run after passing through automatic cut-outs and fuses. The average pressure between the feeders is indicated by four voltmeters constantly in circuit, and there are four other voltmeters with switches for showing the pressure between any two feeders at any distributing point.

In the conduits for the distributing system the insulators carrying the copper conductors are so arranged on their supports, fastened to an iron cross arm, that the distance between two neighboring strips is always 100 mm. Copper conductors are employed from 5 to 345 mm.^{2}, and in length from 6 to 20 m. A number of S shaped flexible strips are inserted at intervals to allow for contraction and expansion of the conductors with changes of temperature. The house services are taken off with two, three, four or five wires according to the amount of current to be supplied, and the regulation of the system is stated to have given entire satisfaction. The above details of this plant are taken from a description in *Electricity*, London.

The New York Electrical Society.

The next meeting of the New York Electrical Society will be held at Columbia College on Tuesday, Jan. 16, at 8 P. M. Prof. M. I. Pupin will deliver a lecture on "Electrical Resonance," accompanied by experiments showing the properties and influence of self-induction and capacity on electric circuits.

Patent Litigation—II.

Absurd Basis for One of the Patents.

Compound Winding Described Twenty Years Ago.

THE STATUS OF COMPOUND WINDING PATENTS.[†]

One of the most important patents which have been claimed in course of the patent litigation launched by the General Electric Company is the United States patent of T. A. Edison, granted September 19. 1882, for a "regulator for dynamo electric machines," the application for which was filed in August of the same year. The specifications of this patent describe compound winding, or the combination of the shunt and series methods, and the object of the invention is stated to be the automatic regulation of the current when the load of the dynamo is varied.

The claim of the company to the exclusive right to use this method of winding is not new. It was put forth with emphasis and with unblushing assurance by Mr. F. P. Fish, at the hearing before the State House Commissioners in Boston on July 18, 1892, when the Mather Company were in controversy with the General Electric Company. Mr. Fish's contention was at that time that no other company in the United States could carry out the specifications for the State House plant without infringing the patents of his company.

It is a matter of surprise to everyone familiar with the history of the art how a patent for this device could have been issued in 1882, as compound winding had not only been described and put into practical and commercial use several years previous to Edison's patent, but a prior United States patent for precisely the same thing had been granted more than two years before. A brief historical glance affords evidence of the truth of these statements, and will be of interest in view of the exclusive claim of the General Electric Company to this winding.

The earliest description of compound winding dates back to 1871, when it was mentioned by Sinisteden in *Poggendorff's Annalen*, and the first machine employing this principle was built by Mr. S. A. Varley, who obtained a patent for it in England in 1876 (No. 4,905). In this machine both a shunt and a series winding were used, both of which were wound on the field coils and both running to the lamp. The shunt coil, also, was a closed circuit, the lamps being connected in the low resistance circuit. This winding differs from that used to-day in having the shunt circuit carried parallel to the main external circuit to the lamps, but it has been declared in the Scotch courts to anticipate the Brush patent for compound winding, which was granted in 1879, and which describes the method in general use at present. That this subject was not novel at that date is evidenced by the fact that C. F. Brush and Edward Weston had filed simultaneous applications for patents on this device which were in interference. As the same parties were also in interference on another patent, the matter was compromised by agreement, Mr. Brush taking the patent on compound winding and Mr. Weston taking the other patent in dispute.

Brush's application was in interference with the application of Edward Weston filed June 6. 1877, the issue of the interference being the second claim of the Brush patent, mentioned below.

At the same time there was another interference, Weston vs. Brush, involving a ventilated armature for dynamo-electric machines. The latter case was "Case B," and the former one "Case A."

[†] On page 296 of our last issue the statement that 1,200,000 foot pounds is contained in ⅛ ounce of good coal should have read 1⅛ ounces. Error was also made in referring to Judge Green as a United States Circuit Court Judge, Judge Green sitting in the United States District Court.

The parties made cross concessions of priority, Weston conceding priority to Brush in "Case A." and Brush conceding priority to Weston in "Case B." No testimony was taken in either case, and the preliminary statements were subsequently withdrawn.

Previous to the settlement of this interference case, Mr. Weston had built more than a dozen compound wound machines for electro-plating purposes (some of them in 1877) which were sold through Messrs. Condit, Henson & Van Winkle, who were then the selling agents for the Weston Dynamo-Electric Machine Company. These machines were sold in New England, and some of them are believed to be still in use. They were referred to in the catalogue of Condit, Hanson & Van Winkle for 1878.[*]

The Wallaces, at Ansonia, had built and sold, *before* 1879, more than one hundred small machines wound in this manner, many of which must still be available.

In the early part of 1878, Messrs. Siemens & Halske shipped to this city from Berlin a compound wound machine, which is still believed to be doing good service and which could be easily located.

Brush had built a number of them before the interference case came up; they were well known in the trade under the name of "Teaser Machines." One of them was installed in Sing Sing Prison in 1878.

Brush was undoubtedly the first to use a compound winding of the usual kind employed at present, and incontrovertible proof of the fact that these machines were identical with the present compound-wound dynamos will be seen by reference to the specifications of Brush's patent of July 22, 1879, which states:

> "*My invention has for its object the maintenance in such (dynamo-electric) machines of a 'magnetic field' while the machine is running, whether the external circuit is closed or open.* . . .
>
> "*I attain my object by diverting from external work a portion of the current of the machine and using it either alone,* **or in connection with the rest of the current,** *for working the field magnets. I prefer the latter plan of the two just above mentioned, especially for electro-plating machines.* . . .
>
> "*In applying my invention to dynamo-electric machines I wind the cores of the field-magnets with a suitable quantity of comparatively fine wire having a high resistance in comparison with that of the external circuit and the rest of the wire on the machine. The ends of this wire are so connected with the other parts of the machine that when the latter is running a current of electricity constantly circulates in such wire whether the external circuit be closed or not. The high resistance of this wire prevents the passage through it of more than a small proportion of the whole current capable of being evolved by the machine; therefore the available external current is not materially lessened.*"

This description covers the present method of compound winding as accurately as it could be expressed, and this fact is still further emphasized by the drawings which accompany the specifications of the patent, and which show the shunt and series windings on one or each magnet-core and include every possible disposition of the two windings.

From the foregoing description it appears probable that all of the advantages of compound winding were not appreciated by Brush at that time. The shunt coils-- then called "teasers"—were adopted at first to prevent a reversal of polarity in the machine when the external circuit was broken, but their functions as regulators at once became apparent, as in 1878 a machine built by Brush was practically self-regulating, showing a variation of less than one volt in pressure through its extreme range of 300 amperes.

About two years subsequent to the date of Brush's patent of 1879, Marcel Deprez demonstrated theoretically the fact that at its normal speed a dynamo would be self-regulating in regard to pressure if wound with an auxiliary coil furnishing a constant excitation of the field-magnets independent of the series coils, and his conclusions were published in *La Lumière Électrique* of December 3, 1881.

Eight months after this publication of Deprez's, and four years after the commercial use of compound wound machines by Brush, Weston, Wallace, Siemens and Halske, after the idea had been described and redescribed and was thoroughly understood by scores of practical workers, an application was filed by Edison for the same device covered by Brush's patent, with the object of self-regulation described by Deprez. To show the absolute identity of the Brush and Edison patents it is only necessary to compare the claims of these patents. In Brush's patent the claims read as follows:

> (1) In a dynamo-electric machine the wire or helix E[*] having a comparatively high resistance and kept constantly in closed circuit while the machine is running, in combination with the magnet wire or helix F[*], as commonly employed.
>
> (2) In a dynamo-electric machine in which the coils around the field-of-force electro-magnets are included in the main or operative circuits, the combination of such main circuit with a constantly-closed differential circuit of prescribed resistance, for the purpose of maintaining the flow of the current through the coils surrounding the electro-magnets in the machine when the main or operative (external) circuit is broken, substantially as shown.

Edison's claims are as follows:

> (1) The combination, with a dynamo-electric machine and devices arranged in multiple-arc of a field circuit of constant resistance for primarily energizing the field magnet. and another circuit whose resistance is varied by the addition and removal of translating devices, substantially as set forth.
>
> (2) The combination, with a dynamo-electric machine, of one of its main conductors forming a portion of coils of its field magnet, a circuit for primarily energizing such field magnet, and translating devices arranged in multiple arc or divided circuits whereby the addition of each individual translating device causes a corresponding increase in the energy of the field magnet, substantially as set forth.
>
> (3) The combination of a multiple-arc circuit containing a portion of the coils of the field magnet of a dynamo-electric machine, a multiple-arc circuit containing the armature of said machine, and multiple-arc circuits containing lamps or other translating devices, all such multiple arc circuits being derived from the same main conductors, and another field circuit whose resistance is varied by the addition and removal of translating devices, whereby the addition or removal of any translating device causes an instant and corresponding regulation of the current energizing the field magnet of the machine, substantially as set forth.

It will be seen at a glance that the claims of both the patents describe exactly the same device, although each inventor uses it for a different purpose. In the Brush claim the expression "in which the coils around the field-of-force electro-magnets are included in the main or operative circuits" includes very broadly the combination claim of Edison of a multiple arc circuit containing translating devices.

The only question of difference between the two patents is, then, the purpose for which the device is used, and an old invention applied to a new use is not a patentable novelty, as it is not invention to use an old thing or process for a new purpose.

The decisions of the Supreme Court on this point have been numerous and are unanimously in accord with the foregoing statement. An illustration of this is the case of Brown vs. Piper, in which the Court held that a patent for preserving articles in a close chamber by means of a freezing mixture having no contact with the atmosphere of the preserving chamber, described nothing but a double use of the ordinary ice-cream freezer, and was therefore not patentable. Also in the case of Tucker vs. Spaulding the patent covered the combination of a circular disk with removable saw teeth. There was a prior patent of the combination of a circular disk with removable cutters for the purpose of cutting tongues and grooves, and it was held that the latest patent was but a double use of the older one and was not an invention.

These cases appear analagous to the case of the Brush and Edison patents on compound winding of dynamos, and it is probable that if the latter were brought before the court Edison's patent would be declared only a double use of the older Brush winding on which the patent has expired.

In addition, however, to the evidence that Brush's patent anticipates that of Edison by more than two years, there are several other causes which should operate to invalidate the latter patent, and which are indicated in the bill of complaint in the case of the Edison Electric Light Company vs. the Mather Electric Company, now pending. This bill recites:

> "That heretofore, as your orator (the plaintiff) is informed and believes, and prior to the seventh day of August, 1882, Thomas Alva Edison, being then a citizen of the United States, residing at Menlo Park, in the County of Middlesex and State of New Jersey, was the true, original and first inventor or discoverer of a certain new and useful invention, to wit: An Improvement in Regulating the Generative Capacity of Dynamo-Electric Machines, and that the said invention was not known or used before his invention or discovery thereof, and had not been patented or been described in any printed publication in this or in any foreign country, and was not, and had not been at the time of the application for letters patent therefor, in public use or on sale in this country for more than two years, nor contrary to the provisions of the Statutes of the United States in such cases made and provided; and had not been abandoned to the public."

In view of the amount of prior use of this device and the number of publications in regard to it previous to Edison's application, the complainant's information seems to be peculiarly deficient, and it is incomprehensible how, if compound winding was not known or used prior to the date of the Edison patent, Mr. Edison had before that time put himself on record by publicly claiming that compound winding was of no value. This fact at least should have been within the knowledge of the plaintiff.

The use of this winding by Brush and Weston in 1878 and 1879, the descriptions of it by Sinisteden in 1871, already mentioned by Sir C. W. Siemens in *Philosophical Transactions*, March, 1880, and by Alexander Siemens in the *Jour. Soc. Telegr. Eng.*, April, 1880, besides the theoretical deductions of Marcel Deprez in *La Lumière Electrique* (1881), quoted above, in which he shows that this winding should act to effect self regulation, all are well known, and the printed publications have been frequently quoted in a number of scientific books.[*]

We have been asked why the Edison people had not laid claim to the patent earlier, over half the life of the patent already having elapsed. We are unable to answer this question, and shall await with some curiosity the answer which will be made to it by counsel of the General Electric Company when the case comes before the courts for argument.

We grant that the glamour which surrounds everything labelled "Edison" is such as to blind the eyes and deaden the perceptions of not only the public but of able jurists; but we do not believe that the managers of the General Electric's patent campaign have so far lost their wits as to believe in their case on this compound winding matter. We do not believe they will ever argue the case. We do believe that they will bring a number of suits against contractors who cannot defend them, and manufacturers who do not consider the idea essential for their machines, and in this way the General Electric Company may get decisions in its favor. Moreover, while suits are pending they can no doubt be used as effective arguments to persuade contractors and purchasers generally that Edison apparatus is the only safe apparatus to buy.

---

[*] It is worthy of notice that the catalogue of this company for 1879 refers to a new type of dynamo machine, from the description of which it is manifest that Weston was far in advance of other American inventors in conceiving and successfully adopting the idea of automatic regulation.

[*] Letters refer to patent drawings.

[*] See Dynamo-Electric Machinery, S. P. Thompson, 4th edition, p. 61.

The injustice of such abuse of absurd patents which have by hook or crook come through the Patent Office is apparent and does not require comment. But this we believe to be the policy of the General Electric Company. It is a fact that those in control of the company at present have pinned their faith to these Edison patents, and believe that they can be so manipulated as to bring forth success from the jaws of disaster.

Will they win? The answer to this question lies in part with every manufacturer and contractor liable for suit on any of the patents at present under discussion.

The plan of economy and safety is the raising of a common fund for the defence of these suits under the direction of the only attorneys who have won important battles for the independent concerns in the trade.

The third and last article in this series will be devoted to the Edison three-wire patent.

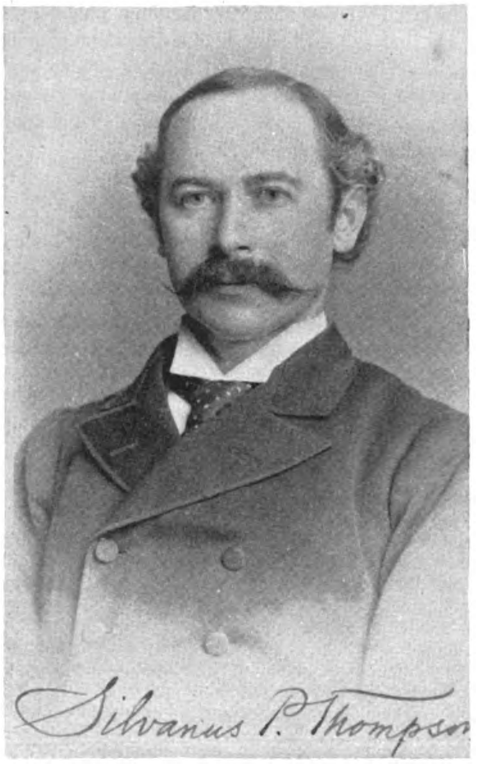
Technical Education in England and America.

Professor Silvanus Thompson's Views.

Professor Silvanus P. Thompson, who is the principal of the celebrated City and Guilds of London Technical College, Finsbury, is actively interested in the educational work that is being pushed by the wealthy old public bodies of the British metropolis with the object of enabling England to stand the strenuous competition of other European nations in the arts and sciences.

While in this country, Professor Thompson was interviewed by a representative of ELECTRICITY, and on being asked "What is being done in England in the matter of technical education?" Professor Thompson said:

"We have many schemes of technical education that are now developing both in London and in the provinces. There is much being done, but one cannot exactly say what it is, simply because it is growing so fast. Since the passing of the Technical Education Act, three years ago, which placed at the disposal of local bodies certain beer and spirit dues for the purpose of technical education, there has been much done and more begun. For example, in Birmingham the municipality has taken over the educational part of the Midland Institute, and is developing it into a large and important municipal technical school, which will have both day classes for students who give two or three years systematically to the work and the evening classes which were begun years ago by the Midland Institute. Again, in Manchester there is a magnificent technical school growing up under the municipality, partly from those beer and spirit dues, but having a large endowment from the bequest of the late Sir Joseph Whitworth. Also in Glasgow there is a splendid technical college for the West of Scotland. These three technical establishments are the best institutions in the provinces, and contain large laboratories, workshops and studios, and in fact all the appliances for a thoroughly practical education. One very important matter in connection with these movements is that they are taking their individual tone and strength from the industries of the places in which they are located. Until these funds were available locally, the only way of encouraging classes in applied science was from the funds administered from South Kensington by our Science and Art Department. These organizations did very good work for many years, but they are too often out of touch with the local industries. In London, the great work begun fifteen years ago by the City and Guilds' Institute has not extended as widely as some of its early supporters had hoped, but nevertheless it has two great colleges of applied science, the central institution at Kensington and the Technical College at Finsbury, both in a very flourishing condition. In these establishments, which have extensive laboratories and workshops, the courses are of a very high grade, and great pains are taken to secure as instructors men who, while having sufficient knowledge of theory, are thoroughly acquainted with the practical or workshop side of the subjects they teach. We look upon this as a prime requisite, and think it a great mistake for a schoolmaster to attempt to teach what he doesn't know. We prefer to take a man right out of the industry, who has the faculty of teaching, and pay him sufficiently well to make it worth his while to stay there. We have been particularly successful at both of these colleges in training young mechanical and electrical engineers. Of more recent growth in London are the polytechnic institutions, now some half dozen in number, which are more elementary, and include recreative work, which indeed in some of them takes the most prominent part. These institutions, which have been supported hitherto mainly by individuals or private corporations, are now aided by the funds diverted from the antiquated City Parochial Charities."



Silvanus P. Thompson

"Does your special educational experience lead you to think that for an electrical engineer the college training should precede, be combined with, or follow work in the shops?"

"Everything depends upon the temperament and previous training of the boy. In many cases it is undoubtedly best for him to go to the shops for a couple of years before his training at the technical college. Some of the best technical college pupils in my experience have been those who have had some previous experience of industrial life; but there are others for whom it is certainly better to defer entry into the factory until after they have had a year or two of technical training in the college. An intermediate system is possible, but only where the employers in the district are willing to co-operate with the technical college. This is the case among the engineers in the West of Scotland, and also in Bristol. The students of the Glasgow Technical College and of the technical department of the University College at Bristol can take a mixed course, spending the winter six months in the college and the summer six months in the factory. This system has been found to work admirably, for each kind of training helps the other.

"Until now it can hardly be said that the training given in any of the establishments in London I referred to replaces the old apprenticeship system, for the simple reason that employers are intensely conservative, and often sneer at efforts to teach in the schools anything that is of value from a practical point of view. But with the efforts to secure as teachers practical men who have had experience in the workshops, this feeling is dying away. There is another difficulty which technical education in the colleges has not yet met, namely, all the large firms receive pupils who pay large fees for the privilege of entering the profession or industry in a gentlemanly kind of way. In large engineering works, for example, there will often be a considerable number of idle young gentlemen who have paid their $1,500 to $3,000 for the privilege of going through the shops of that firm. Many of these learn little or nothing. It is difficult for the youth who has been trained in a technical college to find employment in such establishments unless he also is willing to pay the same fee as the young man who has had no training. This vicious system will die out, but at present it blocks the road to progress, for during a time of commercial depression there is a great temptation to managers to keep their works going by the fees from new articled pupils."

"How does the work done in English technical colleges compare with that done in American institutions?"

"It compares very favorably with that of such institutions as Cornell University and the Massachusetts Institute of Technology, but as a rule the day students do not stay long, but take a short course of two or three years. Indeed, we do not encourage them to stay longer, because no college can possibly give to a young man the same kind of training as he can get in the industry, where he is learning not only applied science but the art of managing men and of working to gain money. On the whole, I think the courses of instruction in England are a little less theoretical than those in this country. I have taken great interest in the Pratt Institute, Brooklyn. This compares closely with the polytechnic schools in London, and in many respects is superior to them. Those institutions which make so much of the recreative side cannot be as thoroughly in earnest as an establishment which devotes itself entirely to educational ends.

"You ask me about electrical engineering in our respective countries. Well, there are many points in which we can learn from you, and I think there are a good many also in which you can learn from us. We move very slowly, but for that very reason whenever we do anything we think it is done more perfectly and with more forethought than would be the case if the work had been rushed along. Our two electric railroads are, for example, much more solid and complete than anything you have on this side of the water, and they are *real* railroads, to which the nearest approach in this country is the intramural elevated road at the World's Fair. Electric car lines, of which you may have hundreds, are practically unknown with us, for the reason that with only two exceptions, so far as I am aware, our local authorities absolutely forbid the use of the trolley. I think we have only two trolley roads in the whole of England. It is not that we are opposed to electric locomotion, but our local authorities have set their faces against the use of overhead trolley lines. We have attempted to work two or three roads by means of accumulators, but these have not been a great success, owing to the difficulty of finding electric accumulators that will stand the racket of a jolting car. I have no doubt that accumulators can be made which will not deteriorate seriously with vibration, and which will not be too heavy for practical purposes. When once we have such accumulators, we shall have a great development of electric roads; but I do not think that trolley lines will ever become popular in England."

"Do you think there is any chance for the electric railroad conduit system in England?"

"I hardly think so, at all events judging from present indications. The conduit is too difficult to keep in order. Both its electrical and mechanical difficulties are very great and virtually prohibitive. They have a conduit road at Budapest which is working satisfactorily, but such a slot as they use would not be tolerated in England."

"Do you consider that England is abreast of us in electric lighting?"

"I am struck by the way in which electric lighting is used in this country, in the little outlying towns and villages as well as in the large cities. Our small towns and villages in England have hardly begun in electric lighting. They all have their little gasworks, which they cannot afford to change, or which they think they cannot. In our large towns electric lighting has progressed during the last four or five years considerably, and now it is the rule for the municipality to own its own electric station, just as it owns its gasworks or its waterworks. In London, however, the lighting is almost exclusively in the hands of stock companies. There is much less use of arc lamps for street lighting than is the case in America; but in the matter of domestic electric lighting I think we might give a good many points to American engineers. In one thing England is immensely ahead of the States, namely, that our industries, old-fashioned though they may be, are not cramped and torn to pieces by unscrupulous monopolies. The electric lighting companies in London are absolutely free from the tyranny of any monopoly holding rights on underground conduits."

"Do any other points of difference in electrical practice between England and America strike you?"

"I have been gratified at seeing the use that is being made in this country of electricity for motive power. This would be impossible if you had not for some years had a constant supply of current from central stations. I am struck by the very large use made of electric motors—for example, ventilating by means of fans. No doubt we should have the same in England if our climate required it. We have the motors and the fans, but when, once in a few years, we do have a spell of really sweltering weather, the Englishman buys a cheap palm leaf and cools himself."

Starting Multiphase Motors.

In starting multiphase motors having a closed circuited secondary member, it is found that the best starting torque is obtained when the resistance of the secondary element is considerably higher than would satisfy the best running conditions. This is because the resistance of the secondary best suited to efficient running is so low that the primary rush of current flowing through it on starting from rest is large enough to exercise a demagnetizing effect on the field so great as to materially decrease the starting torque. It has therefore been not unusual to connect with the secondary element a starting resistance, which later is removed from circuit. When the secondary element is the stationary part of the motor, this is very simply done by connecting properly in circuit with it an ordinary rheostat. In such case, however, collecting rings are required on the revolving member in order to supply it to the primary current. If on the other hand the secondary member is the revolving part of the motor and a fixed non-rotating rheostat is used, sliding connections are again necessary in the circuit of the rheostat. It is desirable to avoid the sliding contacts altogether, and this is the main object of a recent invention by Dr. Louis Bell, who makes the primary member the fixed part of the motor, and uses a starting resistance which revolves with the secondary member. The resistance is non-inductive in character, and a switch for short circuiting it is provided which also travels with the armature or revolving member, and which may be thrown while the motor is running, manually or automatically. —*Exchange.*

The failure is announced of the Railway Equipment Company, of Chicago.

A VAPOR LAMP.

The Star Electric Company Has Found Something New.

Mr. John Von de Kammer, electrician of the Star Electric Lamp Company of Chicago, who was one of the first to bring out a successful gas lamp, has perfected a Vapor Lamp which has created something of a sensation in Chicago.

The new lamps are now on exhibition at the rooms of the Ansonia Electric Company, and are attracting much attention. Some tests have been made with this lamp which are quite remarkable. One of the regular 16 C. P. lamps was over-run until the light produced measured on the photometer over 700 candles, and when afterward the filament was measured it was found that the resistance was no higher than at the start and the lamp had not been injured. It is well known that if the ordinary vacuum lamp is over-run but a few volts the lamp is practically ruined.

It is thought from these tests that the lamp will prove far more economical than either gas or vacuum lamps.

Another Large Scheme.

Electric Road Between New York and Philadelphia Proposed.

The United Press has the following:

The plans of the New Jersey Railway Company have been made public. The scheme is to build the longest electric road in the United States, connecting Philadelphia and New York.

Joseph H. Reall, of Bloomfield, is the projector of the enterprise, and associated with him are Charles E. W. Smith, of Morristown; J. H. Baldwin, of Orange; George S. Forbush, of Boston, and Major John Rurk.

Mr. Joseph H. Reall has always been a man of large ideas, and we are not surprised to find him in a new rôle. His tastes have always been of a pastoral nature, and he has owned, perhaps does yet, the finest herd of Jersey cattle in the State of New Jersey. He is also an expert judge of butter and cheese. So far as we know his schemes have always been profitable to himself.

We advise intending purchasers of stock in this new enterprise to hold a post-mortem on the Chicago-St. Louis Through-by-Lightning scheme before they invest, and to ask themselves a few questions as to the present conditions of traffic between New York and Philadelphia. Has the Reading's splendid service been properly patronized, and proved profitable? Is there any need for a new steam road between these two points. If not, what reason is there for supposing that an electric line would fill a long felt want?

The air-line-hundred-miles-an-hour theory will not work in the East.

Northwestern Electrical Association.

The Northwestern Electrical Association will hold its January meeting at the Hotel Pfister, Milwaukee, Wisconsin, on January 17th and 18th. The programme will open with an address by President Collins, of Green Bay. The papers are as follows: "New Things in Electricity," W. W. Low; "Essential Station Instruments," Prof. Jackson, Madison; "Corliss Compound Engines," E. L. Debell; "Advantages of Direct Connection," W. N. Stewart of the Siemens & Halske Electric Company, Chicago; "How Shall Members Buy Supplies?" H. C. Thom. Foreman Collins, Vice-President of the *Western Electrician* of Chicago, and J. McFadden of the General Electric Company of Chicago, will discuss the "Economical Use of Transformers."

A series of evening classes, with a very moderate rate of tuition, has been inaugurated in the department of Electricity and Electrical Engineering of the Armour Institute, Chicago.

Current Items.

An amateur electrician in the town of Dixville, Que., is operating a plant for supplying his residence with electric lights by wind power. This experimenting amateur has installed a small plant of storage batteries in his house, so connected to a dynamo and wind wheel that the whole arrangement works almost automatically. At a short distance from his dwelling he has erected a tower 58 feet high. Upon this tower is a 16-foot galvanized steel wind wheel, which is connected by a vertical shaft to the machinery below. In the base of the tower there is a room 14 feet square, in which are dynamo, regulators, automatic switches and other accessories. The dynamo is a 1,000-watt machine, with certain improvements which make it more suitable for work. Connected with the countershaft is a regulator which keeps the electric potential at a uniform voltage. There is, in addition to this, an electro-magnetic switch that opens and closes the circuit of the charging current whenever the potential of the dynamo, in stopping, falls below the voltage of the accumulators, or rises above it in starting. The storage batteries referred to are designed to lay up a supply of electricity sufficient to light the lamps for three or four evenings in case of a lack of wind for motive power.

M. Moison, a French electrician who has been experimenting with diamonds in the electric arc, says: By starting the arc slowly and placing a diamond in the crater, it is brought to incandescence and increases in size, covering itself with a black mass formed entirely of graphite. When the diamond is placed in an electric furnace it breaks into small fragments, each of which is changed into graphite; the stable form of carbon at the temperature of the arc is therefore graphite; in an oxy-hydrogen lamp at a temperature of 2,000 degrees, a diamond was covered with a black coating, but he never obtained any graphite.

D. H. Kent, of St. Paul, is the inventor of a telegraph typewriter, bearing his name, which, if successful, will eventually displace the Morse system entirely. The operator plays upon the keys of the instrument, as in any ordinary typewriter, but the resulting manuscript is produced at the telegraph office or station where it is to be delivered, which may be a thousand miles away. The main advantages to be gained by this over the Morse system are three in number—more words a minute can be sent, there is no receiving operator at the other end of the line to make blunders, the one to whom the message is addressed is not left in the dark by a blindly written message, every word being produced as it was ticked off by the transmitting operator.

A Connecticut paper mentions the peculiar origin of a fire which occurred recently in a dwelling house in Norwalk. An electric railway passes the place, and it appears that the return current, some of which escapes from the rails into the ground, followed an iron water pipe into the cellar of the house, then switched off to a gas pipe at a point where the two came in contact, and followed the latter to the meter, where it melted the lead connection and ignited the gas. The flames had caught the floor timbers when they were discovered, but the fire was extinguished with but trifling damage.

A new submarine torpedo boat built by Richard Radatz has been tested at Oshkosh, Wis., and found to work well. The boat is forty feet long and propelled and lighted by electricity, storage battery system. The boat carried three men and remained under water nearly an hour under perfect control. The inventor has several offers, but is waiting to hear from a proposition made to the Government.

The London, Brighton and South Coast Railway of England has thirty of its trains lighted by electricity, and is now about to equip a number of additional trains. It is said that about 15 per cent more work can be got out of an electrically lighted than of a gas lighted train, which makes a saving in first cost of about $225,000, as 85 electrically lighted trains can do the work of 100 gas lighted trains.

ELECTRICITY.

The Popular Electrical Journal.

ELECTRICITY IS PUBLISHED ON WEDNESDAY OF EACH WEEK

Our columns are open for the discussion of any question in which the interests of the Electrical Industry are at stake. News notes, descriptions of new devices with drawings or photographs, are at all times desired.

SUBSCRIPTION RATES:

UNITED STATES, - - - - -	$2.50
IN CLUBS OF FIVE OR MORE, - - - -	$2.00
FOREIGN COUNTRIES, - - - - - -	$4.50
SINGLE COPIES, - - - - - -	$ .10

ADVERTISING RATES:

As ELECTRICITY reaches all classes interested in electrical work, its value as an advertising medium can be readily appreciated. Rates will be sent on application.

Changes for advertisements should reach the office not later than the Saturday preceding the date of publication.

ENTERED AT THE N. Y. POST OFFICE AS MAIL MATTER OF THE SECOND-CLASS.

TRADE SUPPLIED BY
THE AMERICAN NEWS COMPANY,
THE WESTERN NEWS COMPANY.
And their Agencies in all Principal Cities.

NOTICE.—Hereafter cuts will be admitted to the first page of "Electricity," not to exceed one square inch in size.

Conduit Electric Railways. The discussion of the paper on "The Practicability of Electric Conduit Railways," read at the last meeting of the Institute of Electrical Engineers, supports the opinion which we have advanced before, that the success of such a system depends almost entirely upon the dimensions of the conduit and the adequacy of its drainage connections. The system under discussion was that employed in an experimental road at Coney Island, and was described in detail in ELECTRICITY, Vol. 4, No. 25.

It will be remembered that in this system contact is made at intervals of five or six feet by means of a long flexible shoe carried under the car which operates the contact switches placed at each side of the conduit. The idea of this construction is to avoid leakage or short circuits, not by draining the conduit, but by keeping the line entirely insulated except at a point directly under the car. To prove that the drainage was of no consequence in this system, the conduit was filled with mud and water, through which the car was run with but a very slight amount of leakage. Such a test is, however, not at all conclusive except for the special conditions under which it was made. With one car there would be but two or three points of contact at most between which leakage could occur, and the amount of current between them would naturally be small unless the mud was a very good conductor; but in an extensive system using as many cars as some of our street railways do at present, this same experiment would be a very risky one, and would mean a chance of short circuit wherever a car was situated, in many cases twenty or thirty times to the mile. This plan no doubt reduces the danger of short circuits, but it would be obviously unadvisable to build the conduit so small as to introduce the liability of its becoming filled with mud or water.

In regard to the various plans which have been evolved for underground trolley lines to avoid leakage, it can be said in general that their object is attained at the expense of simplicity, and a number of sometimes complicated working parts are introduced necessarily. The actual expense of these constructions would be difficult to estimate, as they have as yet been tried on but an experimental scale. The increase in the cost of running bare conductors in a conduit would apparently be considerable, and the difference would pay for a large increase in the size of a conduit. The latter also appears to be the most logical remedy for the difficulties inherent in trolley conduits, and constitutes to-day the only practical and extensive application of this system that has so far met with success. There is certainly no reason for introducing any complications into a system unless they result in some tangible benefit, and in case of electric railway conduits these special devices have not only proved of no advantage so far, but actually are behind the simple conduit as far as practical application is concerned.

The results of these special systems even in the small experimental lines which have been built are far from satisfactory in most cases, whether due to inherent defects in the system or the temporary character of the construction. A sample road which requires continual repairs and adjustment, sometimes several during a single trip, is not calculated to impress railway men favorably, as their prime requirement is reliability of service.

There has been for some time an accepted general admission that a perfectly simple conduit of sufficient size, carrying bare conductors at either side near the top, is a failure, but the fact exists that its failure still remains to be proved, as no fair trial of the plan has ever been made in this country. Investigation in this direction is perhaps less inviting than that in the line of special and patentable devices, as it does not involve invention but only practical engineering.

This plan, however, is worthy of consideration, as it constitutes the only method which has as yet proved a commercial success abroad or at home.

······o······

We Scoop our Contemporaries. We will be pardoned for calling attention to the fact that ELECTRICITY was the only electrical paper to publish last week the news of the removal of the offices of the General Electric Company from 44 Broad street to Schenectady, and the transfer of a large portion of the staff from the Lynn works.

Thus those who depend upon any or all of our contemporaries for their news were kept in total ignorance of the most important happening in the electrical business world for the past three months.

We know not whether our contemporaries failed to get the news, or whether they were afraid to print it. Probably the latter would be the correct explanation, but for whatever reason, *they did not have the news.*

Even the United Press and the afternoon papers of Wednesday, the 3d, were solely dependent upon our information, and copied our news almost verbatim.

This is only one instance of many, and is merely alluded to because of its prominence.

Giving all due credit to our contemporaries for much excellent matter, we emphasize the fact that in order to get the NEWS you must subscribe for ELECTRICITY.

······o······

WE ARE advised that Mr. F. W. Webster, the purchasing agent of the General Electric Company, to whom attention was recently called in these columns, will not move from Boston to Schenectady, for the reason that his resignation has been called for. This is as it should be. The scandals in his department have been notorious. The man who has ideas of business decency that will permit him to conduct a mica mining business in Canada under the name of "F. W. Webster & Company," shipping all its product to the "American Mica Company, 620 Atlantic avenue, Boston, F. W. Webster Treasurer," which latter company sells nearly all of its product to "F. W. Webster, purchasing agent of the General Electric Company,"—this man, we say, is entitled to a seat in the New York Board of Aldermen. He is wasting his talents in the business world, and is not adding to the purity of business methods. The itching palm is a disease to be eradicated.

A Commendable Progressive Movement. The trade union of workmen in the electrical field known as the Brotherhood of Electrical Workers has inaugurated a movement looking to the educational advancement of its members which cannot fail to commend itself to both employers and employees in this branch of engineering, and which should be emulated by every organization of this character. The plan alluded to, which was briefly outlined in the last issue of ELECTRICITY, has been adopted by the Local Union No. 3 of this order, and includes the organization of a club consisting of 400 members, under the name of the Electrical Workers' University Extension Club, by which, with the co-operation of President Low, of Columbia College, a course of study in electricity and its practical applications will be offered to its members. The fact that the Electrical Contractors' Association has contributed very generously to this project shows that the object of the organization is heartily endorsed by employers of this class of labor.

The officer of the Union quoted as saying, "It is the ambition of Local Union No. 3 to rise above strikes and boycotts, and to educate its members for their own good," has concisely defined the true province of a trade union, and any organization pursuing such an aim must command the favor of everyone concerned in its work.

The members of almost every trade to-day have learned the advantages of organization, and there is hardly any department of trade in which a union of its members does not exist now. The history of trade unions also proves that organization has been a great benefit to the workers in every trade as long as the reasonable and legitimate objects of such associations were not overstepped. The incentive to organization among the various trades becomes very apparent by looking back to the conditions existing a few years ago. The Bricklayers' Association has been for years one of the closest trade unions ever organized, the number of apprentices and new members being strictly limited. The trade was one which obviously demanded no special education or intelligence on the part of its members, nor any outlay for tools, yet solely by reason of organization its members were able to command a salary of from four dollars to four dollars and fifty cents per day, while the carpenter, whose work demanded a far greater degree of intelligence, as well as an investment of perhaps a hundred dollars for tools, could be hired for a dollar a day less. The practical benefit of a union was thus made so apparent that it is now found in every trade, and it wields considerable power in adjusting the relations between capital and labor, and in maintaining labor at a high standard. The power of such unions has, however, not always been wisely used, as the list of unjustifiable and unsuccessful strikes will show, but an effort like that of the Electrical Brotherhood's to educate and advance its members is highly commendable and deserves the coöperation of all interested in the electrical trade.

WE HAVE computed that there are 2,712 people in the United States who borrow a copy of ELECTRICITY every week from their neighbors. This is a serious injustice to the publisher. If you enjoy reading ELECTRICITY, we are entitled to your subscription. If you dance you must pay the fiddler, and we are not printing the liveliest paper in the field solely for fun. Send in your subscriptions; you will get your money's worth every week.

……o……

LOST, strayed, stolen or suppressed—the issue of the *Electrical World* for the week ending January 6. As our contemporary has shown symptoms of mental weakness lately, we fear something serious has happened. A suitable reward is offered.

……o……

WE WERE in error in stating last week that Mr. Charles T. Hughes was among those whose resignations have been called for. Mr. Hughes will remain in his present position, and moreover will still be located in New York. Our issue for the 3d was put to press on Saturday, the 30th December, and there were a great many people talking all at once over our private telephone.

……o……

RESULTS of the move to Schenectady are the reported resignations of Messrs. A. S. Bevis, treasurer, and S. D. Greene, assistant general manager. These two gentlemen have held responsible positions which they have filled with credit. They will carry into new fields the best wishes of ELECTRICITY, and in fact of all who know them.

……o……

WE ARE not able, as some of our contemporaries seem to be, to extract much satisfaction from the fact that prices for incandescent lamps have been materially reduced. The cost of lamps is but an insignificant portion of the cost of a plant, and we doubt if a thousand more lamps will be sold at 30 cents than at 40 cents.

SOLILOQUY OF THE DOOMED.

To go, or not to go: that is the question:
Whether 'tis better in the body to suffer
The chills and aches of Mohawk miasm,
Or to take arms against a score of troubles,
And by resigning end them? To lie awake o' nights
No more; and by a word to say we end
The heart-ache and our allegiance to
A knocked-out company; 'tis a consummation
Devoutly to be wished. To quit, to lose our jobs,
To surrender all our salaries,
Perchance to walk on our uppers: aye, there's the rub;
For in this stagnant trade, what jobs will come
When we have thrown away our boasted snap?
This gives us pause. There's the respect
Due to a regular stipend
Even in Schenectady.
But who would bear the gibes and jokes of friends,
The oppressor's wrong, banishment from the Tenderloin,
The pangs of love broken off short,
The insolence of Directors, and the
Prolonged society of the mosquito,
When he himself might all his shackles break
With an office pen? Who would these fardels bear,
To grunt and sweat i' the ooze of the Mohawk flats,
But that the dread of something worse
Befogs the brain, puzzles the will,
And makes us wonder where we are at.
Thus fat salaries make cowards of us all;
And thus the native hue of resolution,
Is sicklied o'er with the pale cast of thought,
And determinations of great bluff and bluster,
Resignations penned in the hot flush of disappointment,
Are quietly thrown in the waste basket.
We take our medicine,
And decide—to go.

GAS LAMPS NOT EXEMPT.

Temporary Injunction Granted Against the "Novak" People.

Judge Shipman, of the United States Circuit Court for the District of Connecticut, filed a decision on January 8, granting a preliminary injunction against the Waring Electric Company, manufacturers of the "Novak" incandescent lamp, holding that lamp an infringement of the Edison lamp patent, and restraining the Waring Company from continuing the manufacture of the lamps.

Mr. Twombly is Puzzled.

The Accumulated and Well-Planned Mysteries of Eight Years Can't be Fathomed in a Day.

(*"Holland" in Philadelphia Press.*)

"It has cost the General Electric Company and another rival company half a million dollars already to find out which one of them is Julius Cæsar, and they have not discovered it," said one of the keenest of our capitalists this morning; but when I asked him if he could furnish any hint which would explain this mystery, he said that the only one that he could give would be such as would not be flattering to the intelligence of some of the very able men who are associated with that corporation. I heard him mutter something about "hoodwinked" and "buncoed" and "over-reached." but he seemed to be talking to himself rather than to me.

Mr. Twombly, for instance, whose connection with it has caused it to be esteemed a Vanderbilt corporation, is as much mystified about it as any outsider. He says he went into it upon certain representations, and because certain strong men were already in it, but that he paid little attention to it until a few months ago, when he found something was going wrong. Then, quite as much to save his business repute as his money, he gave much attention to it, and yet the more he investigated the less he seemed to know, a condition which he thought could be truthfully suspected of some of the other eminent capitalists who are with him there.

There is a feeling that we are on the eve of important developments in connection with that corporation.

Engaging Board at the Edison.

(*Schenectady Correspondence Albany Argus.*)

The following officials of the Lynn branch of the General Electric Company were in the city yesterday and were registered at the Edison Hotel: E. W. Rice, general superintendent and director of the technical department; W. C. Fish, of the lighting department; F. O. Blackwell, of the mining department; W. H. Knight, of the electric railway department, and H. G. Reist.

Well Informed? Well, Rather!

(*From the Financial Record.*)

"ELECTRICITY, a paper which has been hostile in its criticism of the General Electric Company, but also very well informed, states that steps are now taken to separate the Thomson-Houston from the Edison interests."

Legal Complications Arise.

(*From the N. Y. Press.*)

It is believed that an effort is being made to separate the Thomson-Houston Company from the General Electric, and it is reported that a conference was recently held in Boston, in which Judge Cobb took part, in which the legal possibilities of a syndicate taking control of the Thomson-Houston Company was discussed.

Personal.

Mr. Morgan Brooks, President of the Electrical Engineering Company of Minneapolis, was in town last week.

Mr. R. M. Jones, of Salt Lake City, an old-time hustler for the Sprague Company, has been a New York visitor.

Mr. Geo. W. Conover, for several years the buyer for the Ansonia Electric Company, has resigned his position and accepted the Western agency for the Perkins Switch Manufacturing Company. Mr. Conover is well known throughout the West in electrical circles and the Perkins Company are to be congratulated in securing him as their agent.

A Swindler Abroad.

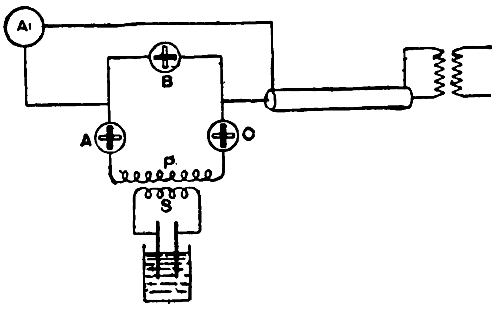
Walter Campbell, who bought the rights for Illinois under the patents of the Electrical Forging Company of Boston, is missing, along with $215,000 which he had collected from sales of stock in the Illinois Electrical Forging Company.

The Electrical Transmission of Power from Niagara Falls.

BY PROF. GEO. FORBES.

ABSTRACT OF DISCUSSION.

Dr. Fleming, in opening the discussion, said it was not always that engineers were to be found who were able or willing to take them into their confidence during the constructive stage of their work, and to tell them not merely what they had done, but what they were proposing to do. He would confine his remarks to two points, and the first was the difficulties which might be expected to appear in all cases where electrical transmission of power was conducted over long lines having capacity and self-induction. These difficulties were not merely hypothetical things which were discussed by Professors, and might, therefore, be safely neglected when coming to practice, but were exceedingly real, and capable of giving rise to very disagreeable and dangerous effects. One of the great risks which had to be avoided in the construction of these lines was the presence of pressure effects, which occurred when the lines were suddenly connected to, or disconnected from, the machines. Prof. Forbes was quite right in saying that under those circumstances surgings were set up in the cables and in the machines, and that the pressure might become almost anything they pleased; it might become scores if not many more times greater than the working pressure; in fact, it was impossible to say under some circumstances what the pressure actually did become, and under those circumstances it was of no use to say anything of failure of insulation, for no insulation would be sufficient to withstand the pressures that were brought against them. The methods by which they could be controlled had only to be known to be adopted. As Prof. Forbes had mentioned that those difficulties had been got over at Deptford, there could be no objection to his telling them the method adopted by his colleague, Mr. d'Alton, in consultation with himself and others. The way in which it was done now was this: The cable was never suddenly connected, but a transformer was placed in the main, and had on its secondary circuit an arrangement by which it could be gradually short-circuited. A water resistance was generally employed, but it might be carbon resistance. The first process of connecting the trunk mains was to keep the switch B open and close A and C, the transformer being open-circuited on the secondary side. Under these circumstances the transformer offered a considerable impedance to the flow of current, and that nullified the capacity effect in the main. The next step was to gradually short-circuit the secondary circuit of the transformer, reducing the impedance of the transformer. When completely short-circuited the switch B was closed, and then the switches A and C were opened, and the transformer was disconnected from the main. In switching off exactly the reverse took place. When dealing with long concentric cables the capacity might reach a very high value—one-third of a microfarad a mile. It was almost impossible to get a cable, if it was concentric, that had not a capacity effect. If they were to adopt a pressure of 20,000 volts, and a frequency of 100, which was probably what they would have done had they started this enterprise in England, and a capacity of one-third of a microfarad with 18 miles of cable, the capacity current in that cable would be 72 amperes when nothing was connected at the other end. That could be easily calculated from the formulae he gave some time ago. The capacity of that capacity current to do work, or rather mischief, was proportional to the square of the current and to the frequency. Hence the advantage of low frequencies, for the capacity was something enormous when they came to long lines. Concentric cables were therefore inadmissible for long lines. He thought there was great safety in using an artificial load in putting machines into and out of parallel. In all Continental stations they did so. When he (Dr. Fleming) was at Rome last Easter he spent a long day with Prof. Mengarini at Tivoli, and the latter allowed him to experiment with the machines there as much as he pleased. They had an artificial load which took up 300 H. P., and this artificial load was made to resemble as closely as possible the real external line. The process of putting the machines in was this: First of all they put them on the artificial line, and adjusted the incoming machines so as to give exactly the required current and volts. They then put on two machines and divided the current without any difficulty; then a third was put into parallel, and then a fourth, and a fifth. They were taken out one by one by reversing the process. That artificial line was used in all the Ganz stations, and he thought Prof. Forbes was very wise in making provision for it in dealing with his machines. It was curious that he had not adopted it much in England. He did not know any place where it was used; yet at the same time he hardly knew any large alternating stations on the Continent where it was not done. In the next place he would say one word on the question of pressure. He was very glad to hear Prof. Forbes say he never intended the primary circuit to be opened. But the question naturally occurred, would not the primary circuit sometimes open itself? In other words, what was going to be done in the way of main fuses? That was really a serious question in dealing with these pressures. What kind of main fuses did Prof. Forbes intend to adopt? In his paper he mentioned a transformer, the secondary of which had a working arrangement which would gradually introduce impedance if the current rose above a certain value. He trusted that the arrangement would be found to work well; but at the present moment one great want in connection with large distribution of alternating currents was an arrangement of main fuses which would not interrupt the circuit, but if the main current went above a certain value would put impedance into the circuit gradually but quickly, and then take it out again as required, but never allowing the main circuit to be broken. The great difficulty at present was that it *did* become broken, and a great rise of pressure took place, with disastrous results to the insulation. The question of pressure was one to which Prof. Forbes and his colleagues had doubtless given very serious consideration before deciding to adopt 20,000 volts. The difficulty which might be encountered with this high pressure was not the difficulty of working with the stock pressure of 20,000 volts, but the tremendous arcs which might be produced if they were started between the conductors. Prof. Forbes did not tell them, he believed, how far apart those cables were going to be in the conduits. He described a conduit in which copper strip was to be used as the conductor, but did not mention what distance they were to be apart. That was a very important matter. It might be impossible under some circumstances to prevent such rises of pressure that an arc would start, and what would be the state of affairs with naked conductors in those conduits if they were only, say, a foot apart? The question was sometimes asked, what is the best frequency to work at? It was very much like asking, what is the best speed to walk at? It depended upon where you were going and what you wanted to do. Continental engineers had not been at work at the matter at haphazard when they adopted a frequency of between 40 and 50. Our adoption of 80 to 100 was necessitated by the circumstances under which we had to start alternate current working; and the same in America. But there was no doubt, he thought, about the wisdom of selecting this low frequency at Niagara, where the utilization of power by motors was an important matter, and there were enormous advantages to be gained by the reduction of these capacity effects and other effects of the same kind by the employment of a reduced frequency.



Mr. W. M. Mordey said they were called upon to discuss a paper on a subject of world-wide importance, and he believed a sense of responsibility would be felt by all speakers. What made the paper so interesting was that Prof. Forbes not merely described the scheme and the works, but went pretty fully into reasons and principles. It was a very important matter that after so much work had been done on alternate current distribution of all sorts Prof. Forbes should come there and throw the gauntlet down to the whole industry on two or three points of primary importance in connection with distribution. Those of them, for instance, who had been working at comparatively high periods had to justify their continued existence and to prove that Prof. Forbes was wrong. Prof. Forbes stated in the paper that "it is a matter of common knowledge that parallel working is assisted by lowering the frequency." With all respect, he (Mr. Mordey) would deny that. He thought there was no evidence whatever to show, with any good plant now running, that lowering the frequency had any connection with parallel working. If there was no difficulty whatever in working at 100 periods there could be no improvement in working at a lower rate. It might be that, with certain types of machines, there were advantages in working at lower rates, but he believed that a machine that was incapable of working at 100 periods would work worse at 16 or 40 periods than a machine that would work at 100 periods successfully. The only definite argument Prof. Forbes put forward was a letter from Messrs. Ganz, who had written him "that their reason in adopting the frequency of 42 periods per second was that it is the lowest frequency that is available with arc lights so as not to produce any serious flickering, and their desire was to lower the frequency as far as practicable in order to ensure parallel working." Now, Messrs. Ganz were very important people; they had large experience all over the Continent, but it was very necessary to examine and sift statements of this sort, and not to accept them as facts. He thought they ought to ask if Messrs. Ganz had not been a little forgetful in making such a statement as that. In his paper on "Alternate Current Working" in 1889 he made a similar statement; he quoted a letter by Mr. Zipernowski to the *Electrician* of May 10, 1889, stating that their low periodicity was "chosen on principle," "that we by this means are enabled to couple our dynamos in parallel is not a secondary result, but just the end we are aiming at." His (Mr. Mordey's) surprise was, therefore, very great when during the discussion Mr. Zipernowski wrote: "We state that we have not reduced the periodicity because of the coupling in parallel," and adding that they had always kept to 85 alternations with only slight variations. He happened to know that this last statement was correct. For a considerable time before parallel working Messrs. Ganz had been making alternators of 42 periods per second; when parallel working was recognized to be a necessity they made experiments and adhered to 42 periods and gave out that they adopted it because it gave the best results in parallel working. I am not aware of any other support than that of Messrs. Ganz to Prof. Forbes's statement, and these words taken from Mr. Zipernowski's own writing showed that his last published statement contradicted his first, and acknowledged that they had made these machines for low periods for years before parallel working was thought of. The question of artificial loading in putting machines on to mains in parallel had also been dealt with by Prof. Forbes, and had been approved very strongly by Dr. Fleming. Now, that was an old, primitive, and he thought an obsolete method. He explained a plan was got out some years ago by Mr. Raworth and himself, and published in his Paper "On Testing and Working Alternators," by which the regulation of each alternator was entirely controlled by controlling the steam supplied to its engine.

(To be continued.)

Legal Notes.

The attachment of the Thomson Houston and General Electric companies against the Little Rock (Ark.) City Electric Street Railway Company having been sustained by Judge Hill releasing the sureties on the forthcoming bond, the attorneys immediately filed an answer, denying the debt, which also contains several counter claims.

Prof. Henry A. Rowland, of Johns Hopkins University, has brought suit in the United States Circuit Court against the Cataract Construction Company for $30,000 for his services as an electrical expert in planning a system to utilize the water power of Niagara for the generation of electricity. Prof. Rowland says he devoted six months to the work and then sent in his bill for $10,000. The company sent him a check for $3,500, which it considered sufficient. This angered Prof. Rowland, and he has brought suit for $30,000, declaring that he charged too little in the first instance.

On application of creditors, George W. Hoadly, cashier of the National Bank of Arizona, has been appointed by the District Court to be Receiver for the Phœnix (Ariz.) Electric Light and Power Company. The company was intimately connected with the defunct Hartford Bank. Reorganization is expected to bring the company around all right, as the franchise is valuable.

The American Bell Telephone Company has begun suit in the United States Circuit Court against the Grand Rapids (Mich.) Electric Light and Power Company to recover damages for an alleged infringement of certain telephone patents which the plaintiff claims to control.

D. E. Connor, ex-city engineer of Covington, Ky., has, it is said, perfected and patented a system of underground trolley for electric cars that is thought to be absolutely perfect. When Professor Clark, of the Patent Office, saw the device, says the Cincinnati *Times-Star*, he advised that it be patented in all foreign countries before being placed in the market, and this has been done. The Cleveland syndicate, controlling all the lines in Covington and Newport and in Cleveland, O., have engaged Mr. Connor to go to Cleveland and change one of their cable roads in the Forest City to an underground trolley line. The system uses a slot the same as a cable road, and a carrier similar to that which grasps the cable. The wire lies dead in the slot except a few feet each side of where it is picked up by the carrier as it rolls along. The system is continuous and does not have to be charged at intervals as is the case with other conduit systems.

G. E. GREEN GOODS.

A Very Tough Man Expresses His Opinion in a Very Tough Manner.

The following is a portion of a circular which was passed around Wall and State streets a couple of weeks ago. It is reprinted here for the benefit of our out-of-town friends who did not receive a copy:

"De undersigned is prepared ter offer ter de public big er little lots uv G. E. at figgers dat'll make de enamel drop off de teeth er de fakirs dat has been workin' de public on Red, N. P., U. P., Atch., N. E. er N. C.

"Dey ain't been no time in de history uv Wall St. dat er more convenient class er Goods hev been shown up et easy prices.

"De Goods we offer'll nail er sucker every time, an' fer de N. E. an' N. Y. trade dere simply out er sight.

"Dese G. E. Goods ain't no chump stuff dat yer got ter work off down er cellar or under der wharf. Dey has backers, dese Goods has, an' nobody ain't got no license ter kick if he gets nabbed in de act.

"Dese Goods has been shoved by de swellest mob dat ever worked de public an' dere names sells de Goods every time.

"Dis ain't no case er Pullhard, Ringheart, BarkLeod er Watchbury, dat just trow up der hands an' turn de stuff over ter er Receiver when der chips is all blown in, and de suckers whats lost der boodle appeals to der feelins. Yer can bet yer life dese Goods ain't no case er feelins uv any kind.

"De backers er dese Goods has got de sand ter play de game plum to de limit, and keep on playing it when de whole outfit is blown in—chips, cards and de box—and when er chump puts up any squeal 'bout Receivers dey just looks im in de eye and dey say 'Yer er d—— liar, and if yer don't close yer trap and git, we'll put de coppers onter yer,' and den dey gets de papers ter print dat he's er d—— liar, and dat he orter be sent up. Dat's de kind er goods we'se offering yer, an yer can just go broke er dealin' in 'em.

"Ter give yer an idee uv de sand dats behind dese Goods, so thet yer kin figger whedder it's plum safe ter handle 'em, git onter what de backers uv dese Goods has done. Dey sold 'em by de barrel at 120 sluggers apiece, an swore on er stack er Bibles dat in er couple er moons dey'd be sellin' at 150, and when dey got de suckers' stuff dey plunked er down ter 80, an when de chumps squealed for dere mun dey just give 'em de laugh, and told 'em ter be dead game an even up by buying more, an dey did. Den dey swinged er down ter 50, and when dey squealed agen dey asked wha' te 'ell dey was goin' ter do about it, and dey been asking 'em ever since, an yer kin gamble all de dividends that G. E. pays in '94 agin de '93 dividends on dat Western Whiskey Fake dat dey'll ask 'em de same question when de Goods sells at 20 an 10, an when dey is finally deposited in de sewer.

"In closin' dis offer de undersign calls yer attention to dis big advantage day ain't offered wid any oder line uv Green Goods in de market:

"Wid every lot we gives er printed denial uv any story dat any one kin tell about de Goods, an dey'll be signed by de President or de Vice-President or any er de Directors. or by prominent officials or strong friends uv de Goods.

"Den we furnish printed statements er profits ter fit any case dat may come up. We don't give er d—— what yer call fer yer kin have, er dat de Goods is earnin' a thousand er day, or more dan enough in er minit ter pay off de National Debt. and wid every lot goes er big red poster dat day ain't no Court in de land dat cares to monkey wid dis game, an in er few monts dividends 'll be resumed.

"Den again we calls particular attention ter de fact dat de backers er dese Goods don't allow no one ter monkey wid 'em—de minit any bloke interferes wid de game dey get de papers to prove dat he's er d— - lyin, thievin scoundrel uv er bear, who don't know better dan ter tell de public dere is er difference between er National Bank an er Faro Bank.

"Don't forget when yer write fer dese Goods ter give yer right name, fer der ain't no law can tackle dis game, an' keep yer eye on de fact dat we sell assorted lots, an dat de quicker yer buy de higher de price'll be an' de more boodle yer can scoop.

"Holy Gee, if yer only got aboard when de stuff was up ter 120 yer'n had money ter burn. Yours, out fer de stuff.

"LOADEM, SHORTEM & GRINATEM."

Boston Notes.

The Interstate and other local electric stree railways which take their power from the central station located at Farmers, near Attleboro, Mass., had hard luck last Tuesday morning when the station took fire and before it could be extinguished $75,000 worth of engines, dynamos, generators, etc., were destroyed. This serious conflagration completely demoralized about 24 miles of electric railway and throws out of work for the time being over 100 men. The power and light station was not very conveniently situated, so the fire, while a very serious loss, will undoubtedly lead to the building and equipping of a far finer station in the town of Attleboro.

The movement in favor of municipal ownership of gas, electric light and similar enterprises appears to be finding increasing favor in Massachusetts. The placing of all electric wires, too, underground is extending, so that at the present time in four cities, viz., Newton, Salem, Worcester and Holyoke, the telephone companies are placing their wires in conduits of their own. Cambridge made a move in the same direction and with practical results, although the order compelling the change has been passed but a few months. For the benefit of our readers we here insert the order as passed and now being acted upon: "That the mayor be requested to petition the next General Court for such legislation as will enable cities and towns in this commonwealth to construct and maintain conduits and manholes in their respective streets. And that the various companies now maintaining overhead wires be required to place their wires and cables in the conduits of the city, and that such company shall pay to the city or town constructing said conduits such rental as will ensure the return of not less than 10 per cent. upon the money invested in such conduits." Those who supported this order claim that it will hasten the placing of wires underground, and will alleviate all those difficulties that would be likely to occur if the various electrical companies were allowed to construct their own subways. The general opinion is that the order will pass the Legislature and the municipal authorities secure the power they ask and proceed with the undertaking forthwith.

The directors of the New England Street Railway Company, it is reported, have finally decided to declare a quarterly dividend of 1 per cent., payable January 15th, as against 1½ per cent. as heretofore. The question has been a good deal debated whether to declare or pass the dividend. The books show that the dividend has been earned, but the floating debt of the subsidiary companies rather embarrassed the directors until they determined to capitalize it.

The Worcester Consolidated Railway Company's directors have voted to fund the floating debt by the issue of $500,000 five per cent. mortgage bonds.

Although 1894 is only a week old, there is a prosperous electric manufacturing company in this city—the W. S. Hill Electric Company—that has been asked to furnish estimates for no less than six large switchboards; and what is satisfactory to note, so fine a reputation does this firm enjoy for high grade work of the kind that it has already secured several of the contracts and expects to close the rest in a few days.

There is trouble and dissatisfaction between the directors and employees of the West End Railway of Boston. For the present year an elaborate schedule of time and wages had been prepared after full discussion between the directors and the men. The very first day the new order of things took effect the men claimed that the company had taken advantage of them and were not carrying out their part of the contract. The men soon got worked up into a state of excitement, and at one time it looked as though they might refuse to run the cars. They were, however, conciliated for the time being under promise that what they complained of should be set right, and it has been done.

There is weeping and wailing in Lynn among the vast army of unemployed workmen who formerly were engaged in the factories of the General Electric Company, while there is much gnashing of teeth among the stockholders of the now cadaverous Trust against the gross mismanagement of the prevaricating incompetents who have wrecked what was intended once to be a good paying business. There are now something over 400 hands at work in the extensive factories at West Lynn, and according to most men's calculations it is only a short time ere the above force will be materially reduced. To what purposes, after the last car of machinery has been shipped to Schenectady, these extensive buildings will be put is at present uncertain. Rumor has it that a new rubber company, at present in process of organization, will occupy part; another part may be utilized for shoe manufacturing, while a large portion may be utilized by the Boston and Maine Railroad for freight sheds and repair shops. These suppositions are simply in the air and may never assume any more tangible form than airy nothings. May it not be that these huge factories with their splendid equipment will take on life and activity once more and be an integral factor in the future development of electrical science when they have come into the hands of the Siemens & Halske Company, of Berlin, Germany, the enterprising corporation whose advent in this country it was once sought to prevent by sending Mr. C. A. Coffin to Berlin to buy them off? Such is the latest rumor as to the future of the Lynn factory. The whirligig of time brings many changes, and they who live longest will see the most. Meantime the exodus from Lynn to Schenectady continues, and what few of the boys there are remaining are assuming a lively gait in acting on that kindly suggestion made by the Great Mogul, Mr. Coffin, at the time of the formation of the Trust, that the rest of the electric crowd might just as well strike their tents and get out, for he and his friends were going to monopolize the entire business. Yes, in faith, the boys are getting out as fast as they can; but it's the General Electric crowd that's "gitting," while the rest of the electrical fraternity looks on, snickers, and winks the other eye.

General News.

What is Going on in the Electrical World.

Paterson, N. J.—Mayor Braun is in favor of the city owning and operating an electric plant for city service.

Dowagiac, Mich.—Fred E. Lee has purchased the Commercial Electric Light system from the city for $6,000, and has begun operating the plant.

Hoboken, N. J.—The North Hudson Railroad Company has asked council for permission to change its motive power from horse to electricity.

Denver, Col.—The Electrical Specialty Company, capitalized at $50,000, has filed with the Secretary of State a certificate of full paid up stock.

Parkersburg, W. Va.—The *Journal* advocates the building of an electric street railway, and says it would be of great benefit to the city and the suburbs.

Newton, Mass.—The mayor recommends the earnest consideration of the plan proposed by the street light committee for securing a municipal gas and electric light plant.

Attleboro, Mass.—Fire on the 2d inst. completely destroyed the plant of the Attleboro and North Attleboro Electric Company at Farmers Village. The loss will probably exceed $70,000.

Utica, N. Y.—The Utica Electric Light and Power Company has renewed its lighting contract with the city, and will add three new dynamos, with an aggregate of 100 horse power, to its plant.

Hollidaysburg, Pa.—The Logan Valley Electric Railway Company's power house, together with a large amount of rolling stock and machinery, was burned last week. The loss is put at $50,000; the insurance on the property was $40,-000.

Lockport, N. Y.—The Cowles Electric Smelting and Aluminum Company of Lockport and the Pittsburg Aluminum Company have, it is rumored, ended their legal disputes by consolidating, and the local plant will be removed to Niagara Falls by the consolidated company.

Savannah, Ga.—The Board of Directors of the Electric Railway Company as reconstructed is as follows: J. S. Collins, president; T. W. Wrenne, Jacob Paulsen, W. J. Lindsay, W. K. Wilkinson, R. M. Hicks, T. Nugent, H. Logan, H. H. Hull, H. C. Cunningham, W. G. Cooper.

Wyoming, Pa.—Electricity is to be introduced into the Mount Lookout colliery. It is to be for hauling coal inside the workings from the breast to the foot of the shaft. The trolley system will be used. The plant will be located outside, and will be used also to light the workings with incandescent lamps.

Leavenworth, Kan.—The committee having charge of the electric railway ordinance, including the mayor, have reported it unanimously to the city council, recommending its passage. The indications, therefore, are favorable for the early construction and operation of an electric road within the city and to the Fort and the Soldiers' Home.

Omaha, Neb.—The Nebraska Telephone Company expended $240,000 during the past year in the way of extensions and improvements, two-thirds of which was invested in this city. Outside of the city $90,000 was expended in the extension of new lines and the changing of grounded lines to complete metallic circuits.

Kansas City, Mo.—The Kansas City Electrical Works are to engage in the manufacture of the new "Midland" dynamos, which, says a local paper, "will necessitate the employment of a large number of men in the near future and will result in building up an industry in Kansas City equal to any of the great electrical machine shops in the East."

Newark, N. J.—The Consolidated Traction Company has, it is reported, secured practically all the stock of the New Jersey Traction Company, and will therefore have control of all the lines in Newark except the South Orange, the new line from Jersey City to Newark, all the Jersey City and Bergen and Elizabeth lines except the North Hudson and Union County.

San Francisco.—Among the electrical fixtures of the Mid-Winter Fair are a great electrical fountain, a tower nearly 300 feet high studded in all its outlines and crosspieces with incandescent lights to the number of nearly 5,000, a cyclorama showing in eruption the Hawaiian volcano Kilauea and a scenic theatre with grand electrical effects. In addition to these the exterior and interior lighting by arc and incandescent lamps will be on a most elaborate scale.

New York.—The secretary of the Board of Electrical Control reports that during the past year the two subway companies have built in the city 100½ miles of telegraph and telephone subways, and 43¾ miles of electric light and power subways. The city now has 847 miles of telegraph and telephone subways, and 820 miles of the electric kind. In the former there are 32,600 miles of wire, and in the latter 1,300 miles. There are now in New York 6,790 arc lamps for commercial and city lighting, 268,000 incandescent lamps and nearly 10,000 telephones, most of them operated through the subways.

Philadelphia.—The Maritime Exchange of this city has been notified that the telephone line connecting Lewes, Del., with Cape Charles, Va., has been completed, placing Lewes in direct communication with the life-saving stations at Ocean City, Assateague, Watchapwreague and Cape Charles. News of maritime disasters and other information important to shipping interests will by means of this wire be at once communicated to the station at Lewes and from there telegraphed to the Maritime Exchanges in this city, New York and Baltimore.

Baltimore.—Work has begun on the long-talked-of boulevard between this city and Washington, of which an electric railway is to be an important feature. The boulevard will be thirty-two miles long and 100 feet wide. It will be nearly an air line between the two cities. The trolley system is to be used on the cars, and a speed of thirty miles an hour is expected. The work will cost about $3,000,000. The Baltimore and Washington Tramway Company, the corporation undertaking the enterprise, intends to push the work so as to complete the boulevard and the railway in a year's time.

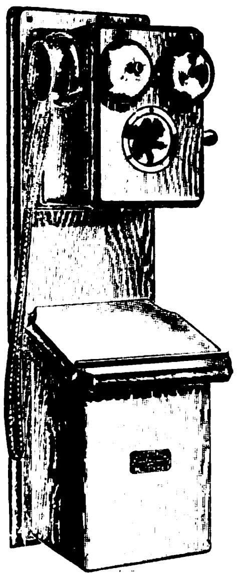
Brooklyn, N. Y.—At the annual meeting of the stockholders of the Citizens' Electric Illuminating Company for the election of trustees for the ensuing year, held on the 3d inst., the present board of trustees was re-elected, as follows: Hugh McLaughlin, John Delmar, James Shevlin, Thomas F. Nevis and Anthony Barrett. —The Railroad Commissioners announce that they have granted permission to the Nassau Railway Company, the Kings County Electric Railway Company, and the Coney Island, Fort Hamilton and Brooklyn Railway Company, none of which has yet been built, to use the electric trolley system on their respective roads, when constructed. — A franchise has been granted to the Thirty-ninth Street and Suburban Railroad Company to run a trolley line through Flatlands and Flatbush to Jamaica Bay.

Hartford, Conn.—The *Courant* states that a large electric railway scheme is being gradually unfolded, including the operation by a syndicate with abundant capital, not local, of the Hartford Suburban Railway Company and the Hartford Light and Power Company. Other companies recently chartered which the Suburban will acquire or control are: The Hartford and West Hartford Horse Railway Company, the Hartford and Middletown Railway Company, the Enfield and Somers Tramway Company and the Windsor and Suffield Tramway Company. The directors of the Hartford Suburban Railway Company are: David Henney, of Unionville, Conn.; Wilbur E. Goodwin, of Elmwood; William F. Henney, W. R. Hurd, William H. Goodrich, Samuel Frisbie, of Farmington; C. M. Henney, F. C. Rockwell, of West Hartford; H. B. Goodwin, J. B. Henney and P. H. Quinn. David Henney was elected president, W. R. Hurd vice-president, Wilbur E. Goodwin treasurer and William H. Goodrich secretary.

Another Boston Telephone.

Well nigh two decades have passed since Professor Alexander Graham Bell, in and of Boston at that time, astounded the world with his wonderful invention, the telephone.

Since the invention was made, patented, sold and placed on the market, along the passing years during which the whole civilized globe has been receiving its equipment, or enjoying the benefits and advantages of the telephone service, the chief offices of the Bell Telephone Company have been retained at the Hub of the Universe. The colossal dimensions and proportions assumed by the parent company have borne unmistakable testimony to the skill and shrewdness of the early exploiters and later the managers of this gigantic business.

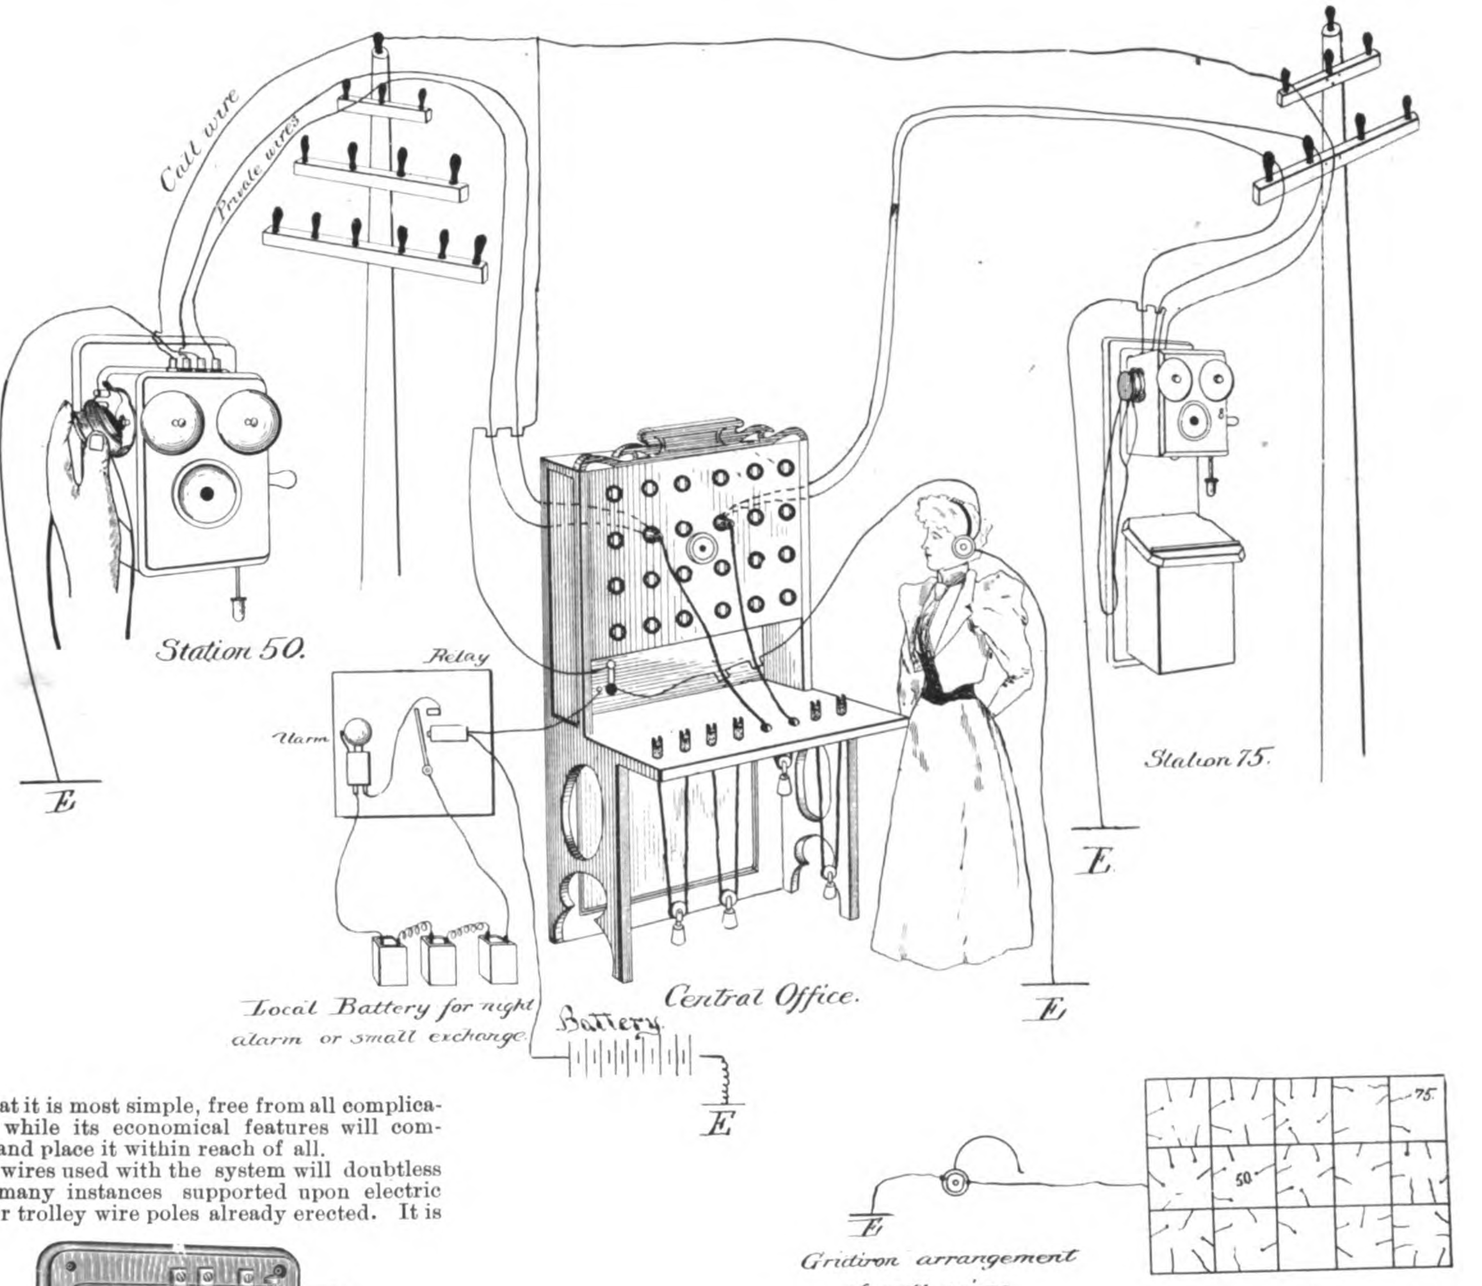


But the seventeen years which constitute the allotted life of an American patent have well nigh run the course, and the 31st day of this current month of January, 1894, will witness the expiration of a fundamental telephone patent which throws open the entire field for the advent of other inventions of a telephonic character which, with the added knowledge, experience and skill of these seventeen years, it is honestly believed will show most marked improvement on the Bell invention and allied auxiliaries.

And again Boston is to the fore in improved telephony, with a sure and certain prospect of more widely popularizing the use of the telephone both in the matter of efficient service and, what is of supreme importance these times, less cost than ever.

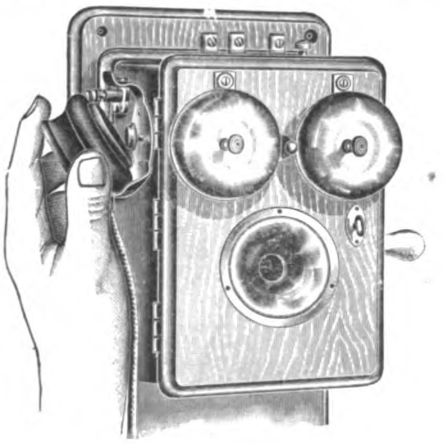
This statement is borne out by the present article and accompanying cuts, which illustrate a new system, the merits and advantages of which are vouched for by more than one of the foremost legal and scientific experts in the country, who have examined, tested and used the same, pronouncing it to be the very thing now needed to fill the bill and give satisfaction to all.

ELECTRICITY has from the first striven to keep its readers posted in each successive stage of development in every department of the art and science of electricity, and has pleasure in publishing exclusively an article descriptive of this latest candidate for telephonic honors, with the assurance that the promoters of this enterprise cannot fail to speedily reap rich rewards for its system. It may be stated, then, that the accompanying sketch exhibits an exchange system decidedly new, for which a patent has been applied. One of the leading patent lawyers in the country assures the owners that they avoid all existing patents; therefore they are prepared to protect their customers from any damages arising from alleged infringement. It is claimed for this system that it is most simple, free from all complications, while its economical features will commend and place it within reach of all.



Gridiron arrangement of call wires.

The wires used with the system will doubtless be in many instances supported upon electric light or trolley wire poles already erected. It is imperatively necessary in such cases that metallic circuits should be used in preference to ground connections, to prevent induction. Two wires are carried from central station to each subscriber. When these wires are connected by operator at central station with any subscriber, the said operator is prevented from listening to the conversation.



A third wire, which is grounded through the head receiver of the operator at central station, "gridirons" the territory operated by the "exchange" and is tapped at each subscriber's station, as shown in cut. This is always an open circuit until the subscriber pulls down the cord at bottom of bell box, which grounds his call wire, enabling him to call "central" for desired connection. For example, telephone number 50 desires to talk with telephone 75. Number 50 takes the receiver from its holder, places it to his ear, and pulls down the cord at bottom of bell box; this connects him with the third or general signal wire running to central station; he then calls into his transmitter "75 on 50," immediately releasing said cord after calling, always giving his own number last, to enable the operator to know who he is. When cord has been released a sharp click will be heard, which assures him that his call has been received; if the click is not heard, he should again pull down the cord and call "75 on 50," releasing the cord as before. When the click is heard, he replaces the receiver in its holder and rings up 75 direct—the party called for.

If upon turning the crank of bell his own bell refuses to ring, it is evidence that telephone 75 is busy talking with some other subscriber, and number 50 will have to call again later on, unless the operator should ring him up, having connected the line in the meantime. After the conversation is completed, before replacing the receiver in its holder, number 50 should again pull down the cord from bottom of bell box and call into his transmitter, "Disconnect number 50"; this must always be done, for should another subscriber desire to talk with number 50, the operator would think his line still in use.

In small exchanges or central stations that may be located in a postoffice or store, or at any place where the continuous services of an operator are not warranted on the score of economy, a clerk or any other party may serve. The operator's instrument can be switched on to an alarm to sound a call when a subscriber desires to be connected, the subscriber pulling down his cord below the bell box and listening until his call is answered by "central," who will connect as requested. To avoid the maintenance of battery at "central" the call wire relay, shown in switchboard diagram, can be operated by the subscriber, who, without removing the receiver, pulls down the bell cord at bottom of bell box and holds it while turning his generator handle; this notifies attendant at "central" that "central" is wanted. He then places receiver to his ear and upon hearing the operator or attendant at "central" calls for number or subscriber wanted.

The above applies only to small "exchanges" or "central offices" where a *permanent* operator is not required.

The subscriber, when connected by "central," is enabled to do his own ringing up, as a call is not always promptly replied to. This feature alone permits the permanent operator to attend to answering calls, making connections without losing time in ringing bells and waiting for delinquents. This will also apply to a clerk or other party acting as operator; they will simply connect the wires, leaving the subscriber to do his own ringing up. The subscriber is also assured of the fact that if he cannot ring up the party wanted it is by no means the fault of central office.

As above stated, metallic circuits must be used in connection with an exchange system if electric light or trolley wire poles are to be utilized. The wire used should be of 14 or 16 gauge hard drawn copper, which is the cheapest wire in the end.

How to Earn Dividends.

It is an axiom that has been demonstrated time and time again since electricity was first used on a commercial scale for light and power purposes that if profits were to be earned upon the capital invested in these new enterprises the coal bin must be considered of primary importance and treated accordingly. Engines, dynamos, generators, indeed every piece of apparatus, whether team or electrical, of the most improved and efficient type might be installed, but if the fuel used under the boilers was not carefully attended to there could be no possibility of ever earning dividends on capital invested. The experience of innumerable lighting and power companies throughout the world proves the truthfulness of this fact, hence it is that companies, presidents, superintendents and managers have tried their best to solve the problem, to overcome the difficulty, and to avoid the loss, with but varying and not very encouraging success. At last, however, many have discovered how to end their troubles and to put their companies on a sound dividend-earning basis. A process has been formulated by means of which most astounding results have been attained, thanks to the enterprise, energy and scientific skill of a corporation known as the Northwestern Land and Coal Company, whose chief offices are in the Ames Building, Boston, with branch offices in the leading cities of the United States.

This company owns and is selling in immense quantities "394," a preparation which combines and utilizes the gases that are ordinarily thrown off in the burning of coal, thereby increasing its heating power. It has been found by practical demonstration to be of great commercial value. It can be used successfully on anthracite, bituminous or lignite, and can be easily applied under the simple instructions furnished for users. It promotes and quickens the combustion of the coal, reinforces the fires, produces a higher temperature, and generates more steam than when coal is burned in its natural state. It prevents the escape of smoke or free carbon, thereby causing complete combustion. It increases the horse power of boilers, prevents the formation of clinkers, makes one-third less ashes, and effects a net economy in the consumption of coal of from 10 to 20 per cent. It saves the grate bars, keeps the flues clean, and displaces blowers, which are expensive to keep in running order. It reduces the labor of firemen. No alterations are required for burning coal when thus treated.

The "394" is being successfully used as a steam producer, fuel saver and smoke destroyer by Electric Light Companies, Water Companies, Manufactories, Cable Roads and in domestic service.

This compound has been tested, experimented with and used by many of the foremost scientific men in the country, and the company is in receipt of most flattering letters of commendation and tabulated analyses of comparative tests all alike testifying to the merits of this preparation. Not only so, but managers of electric light and power plants, water works, textile factories, engine factories and others who now use it regularly are unanimous in their praise of it. They assert that they are effecting a saving in their coal bills of as much as 33 1-3 per cent.

Such a matter as this is deserving the prompt attention of all steam users, and from the substantial recognition already won by it, and the increasing volume of business the company is enjoying, it is clear that this is the sure and certain way at last discovered to earning good annual dividends.

Columbia Lamps at Lower Prices.

The Columbia Incandescent Lamp Company of St. Louis, the only one of the outside lamp companies which defeated the claims of the General Electric Company for the Edison patent, have issued the following announcement:

We beg to advise you that on and after the 10th day of January the price of Columbia lamps will be as follows:

10, 16 and 20 c. p. lamps, - - - -	$.32½ net.
25 " " - - - - -	35 "
32 " " - - - -	50 "
50 " " - - - - - -	75 "
Special railway and anchored filament,	37½ "

The above prices are for barrel lots and over. For less quantities than barrel lots, 2½ cents each will be added.

The same high grade of the Columbia Lamp will be maintained. We are enabled to make this reduction by reason of the magnificent support which has been given us by the users of incandescent lamps throughout the United States during the past year, which has enabled us to largely increase our manufacturing facilities and add additional machinery which has reduced the cost.

The development of electric railroads in Canadian cities has been altogether subsequent to our last tariff revision, and a duty of $6 a ton on steel rails tends to check that development. This duty is not imposed on steam road rails. Delegations have waited on the Government to ask the removal of the duty, which was intended only for horse car lines. The matter is under consideration, but it is expected the duty will be removed. --*Iron Age Canadian Correspondent.*

Reduced Prices for Beacon Lamps.

The Beacon Vacuum Pump and Electrical Company, under date of January 1, announces a new price list, as follows:

16 c. p. in lots of 1,000 or over, - - - -	30 cts.
" " " " 500 - - - - - -	31 "
" " in barrel lots (bbls. containing 200),	32 "
" " in smaller quantities, - - - - -	35 "

They also call attention to the following:

The lamp, which is the invention of Messrs. Nickerson and Cary, to whom over twenty fundamental patents have been granted, was first put on the market last summer.

Since then these experts have been working constantly to reach the high quality which characterized the old Beacon lamp and made it a standard of perfection. This standard has been attained and at the same time the cost of manufacture has been reduced.

The company is now prepared to guarantee satisfaction and prompt shipments, and solicits correspondence from manufacturers desirous of making lamps under N. & C. licenses.

"Acme" Portable Testing Set.

Queen & Company, Incorporated, Philadelphia, are making a renewed push of their "Acme" Portable Testing Set, which was temporarily withdrawn from the market because of certain small defects which have now been overcome in a thoroughly satisfactory manner.

Commercial Note.

Heubel & Mauger, manufacturers of electrical and brass goods, 286-290 Graham street, Brooklyn, have issued a new catalogue calling the attention of purchasers to their numerous electrical specialties. Among these may be mentioned their bells, switches, push-buttons and other accessories for house wiring, all of which are to be commended for their superior quality and reasonable price.

INCORPORATIONS.

The Fuller Incandescent Heat and Light Company, Chicago, Ill.—to purchase, sell, use and operate and license others to use and operate patents, patent rights, generators, motors for generating electricity, etc. Capital stock, $1,000,000. Promoters: J. T. Kretzinger, C. E. V. Akerberg, M. F. Gallagher.

The Universal Electric Heat and Light Company, Chicago, Ill.—to purchase, sell, use and operate and license others to use and operate patents, patent rights, generators, motors for generating electricity, etc. Capital stock, $100,000. Promoters: J. T. Kretzinger, C. E. V. Akerberg, M. F. Gallagher.

The Sidney Power Company, Salem, Oregon—to construct and operate a plant for manufacturing, generating and transmitting electricity. Capital stock, $50,000. Promoters: J. M. Wallace, J. M. Kyle, H. T. Wallace, all of Salem.

The New Decatur (Ala.) Natural Gas, Petroleum and Mining Company, Freehold, N. J.—to manufacture, buy, sell, lease and use machinery, generators, motors, pipes, pumps, apparatus, devices, supplies and articles of every kind appertaining to or in any wise connected with the production, use, distribution, etc., of electricity, natural gas, petroleum, etc. Capital stock, $100,000. Promoters: Thos. Rutter, James Swann, Chas. Y. Kent, New York City; Acton Hartshorne, Freehold, N. J.; John D. Probst, Englewood, N. J.

The United States Wenstrom Electric Company, Jersey City, N. J.—to manufacture, buy, sell and lease electrical dynamos, motors, electrical machines. Capital stock, $80,000. Promoters: Benjamin Blum, Chas. S. Cowan, New York City; Joseph B. de Lery, South Lakewood, N. J.

The Electric Land and Improvement Company, of Orleans, N. Y. Capital stock, $40,000. Directors: Louis Fobes, John Fobes and A. J. Schlager, of Binghamton.

The Toledo and Maumee Valley Railway Company, Toledo, Ohio—to build and operate by electricity or other motive power a railway having Toledo and Perrysburg as its termini, etc. Capital stock, $300,000. Incorporators: Wm. B. Taylor, Josiah D. Cook, George G. Metzger, Parks Foster and Grant Williams.

The Inter-Urban Electric Railway Company, La Salle, Ill. Capital stock, $250,000. Incorporators: C. W. Palmer, R. M. Gardner, M. C. Vanfleet.

Subjacent Electric Wires Traction Company, Chicago. Capital stock, $1,000,000. Incorporators: Charles M. Hill, Charles Rose, Thomas N. McCauley.

ELECTRICAL PATENT RECORD.

LETTERS PATENT ISSUED DECEMBER 26, 1893.

ELECTRIC RAILWAYS AND APPLIANCES.

511,342. Conduit Railway Trolley. John C. Love, Chicago, Ill., assignor to the Love Electric Traction Company, same place. Filed May 17, 1892.

511,343. Trolley for Conduit Railways. John C. Love, Chicago, Ill., assignor to the Love Electric Traction Company, same place. Filed May 17, 1892.

511,346. Trolley Bar Carrier for Cars. John C. Love, Philadelphia, Pa., assignor to the Love Electric Traction Company, Chicago, Ill. Filed Jan. 21, 1893. Renewed Nov. 11, 1893.

511,419. Trolley Wire Crossing. Henry Geise, Philadelphia, Pa., assignor of one-half to Edwin Jaquett Sellers and Horace Pettit, same place. Filed June 26, 1893.

511,452. Conduit for Electric Railways. Henry D. Oler, Paterson, N. J. Filed Aug. 23, 1892.

511,524. Converter System for Electric Railways. Gustaf E. Hesso, Brooklyn, N. Y., assignor of five-eighths to William W. Share and Valdemar F. Lassoe, same place. Filed Nov. 21, 1892.

511,627. Electric Railway Switching Mechanism. Charles J. Kintner, New York, N. Y. Filed June 24, 1893.

511,634. Trolley Base. James L. Mauldin, Cleveland, Ohio, assignor of one-half to Frank J. Lewis, same place. Filed March 20, 1893.

ELECTRIC LIGHTS AND APPLIANCES.

511,495. Electric Arc Lamp. Reginald Belfield, London, England, assignor to George Westinghouse, Jr., Pittsburg, Pa. Filed April 5, 1893.

511,527. Automatic Electric Light Extinguisher. Geo. M. Hughes and George T. Reed, Baltimore, Md., assignors to the Automatic Electric Light Extinguisher Company of Baltimore City. Filed March 17, 1893.

511,613. Rosette for Electric Lights. Charles N. Hammond, Boston, Mass., assignor to the Hammond Cleat and Insulator Company, same place. Filed June 30, 1893.

MOTORS, DYNAMOS, ETC.

511,347. Governor for Electric Motors. John Marty, Jr., Cleveland, Ohio. Filed Oct. 10, 1892.

511,375. Method of and Means for Compounding Dynamo-Electric Machines. Elihu Thomson, Swampscott, Mass., assignor to the General Electric Company of New York. Filed Nov. 23, 1892.

511,448. Electric Locomotive. John G. McCormick, Louisville, Ky. Filed April 1, 1892.

511,523. Current Regulator for Dynamo-Electric Machines. Charles D. Haskins, Brooklyn, N. Y., assignor to the Western Electric Company, Chicago, Ill. Filed Nov. 12, 1892.

511,559. Electrical Transmission of Power. Nikola Tesla, New York, N. Y., assignor to the Tesla Electric Company, same place. Filed Dec. 8, 1888.

511,560. System of Electrical Power Transmission. Nikola Tesla, New York, N. Y., assignor to the Tesla Electric Company, same place. Filed Dec. 8, 1888.

511,570. Rotary Electro-Magnetic Engine. Henry P. White, Kalamazoo, Mich. Filed Feb. 15, 1893.

511,621. Electric Motor Apparatus. William A. Johnston, Arthur W. Browne and John C. Davidson, Prince's Bay, N. Y., assignors to the S. S. White Dental Manufacturing Company, Philadelphia, Pa. Filed April 25, 1893.

TELEPHONE AND TELEGRAPH APPARATUS.

511,358. Telephone. Barton Pickering, Dayton, Ohio. Filed Jan. 29, 1881.

511,456. Telephonic Instrument. Parnell Rabbidge, Sydney, New South Wales. Filed April 22, 1893.

511,462. Fire Alarm Telegraph. Charles H. Rudd, Chicago, Ill., assignor to the Western Electric Company, same place. Filed May 19, 1892. Renewed May 15, 1893.

511,464. Multiple Switchboard System for Telephone Exchanges. Charles E. Scribner, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 26, 1893.

511,589. Telephone System. Frank R. Colvin, New York, N. Y. Filed June 26, 1893.

511,739. Telephone System. John J. McNally, California, Mo. Filed Aug. 31, 1893.

ELECTRICAL MEASURING INSTRUMENTS.

511,376. Electrical Measuring Instrument. Elihu Thomson, Swampscott, assignor to the General Electric Company, Boston, Mass. Filed March 2, 1893.

511,401. Electric Meter. Lucien Brillie, Paris, France. Filed Nov. 22, 1893.

511,508. Electric Measuring Apparatus. Theodor Bruger, Bockenheim, near Frankfort-on-the-Main, Germany, assignor to Hartmann & Braun, same place, Filed Aug. 19, 1893.

511,647. Electric Grain-Weighing Scale. John Outcalt and David De P. A. Outcalt, Spotswood, N, J. Filed July 8, 1893.

INSULATORS.

511,611. Insulator. Charles N. Hammond, Boston, Mass., assignor, by direct and mesne assignments, to the Hammond Cleat and Insulator Company, same place. Filed Sept. 1, 1892.

511,612. Insulator. Charles N. Hammond, Boston, Mass., assignor to the Hammond Cleat and Insulator Company, same place. Filed April 12, 1893.

CONDUCTORS.

511,344. Support for Electrical Conductors. John C. Love, Philadelphia, Pa., assignor to the Love Electric Traction Company, Chicago, Ill. Filed Jan. 21, 1893.

511,345. Tension Device for Electric Conductors. John C. Love, Philadelphia, Pa., assignor to the Love Electric Traction Company, Chicago, Ill. Filed Jan. 21, 1893.

MISCELLANEOUS.

511,328. Method of Electric Commutation and a Fluid Electric Commutator. Charles E. Emery, Brooklyn, N. Y. Filed Dec. 28, 1892.

511,434. Galvanic Battery. Harry T. Johnson, New York, N. Y. Filed April 21, 1893.

511,451. Electric Bell. Augustus J. Oehring, Chicago, Ill., assignor to the Western Electric Company, same place. Filed April 25, 1891.

511,461. Safety Device for Electric Circuits. Charles H. Rudd, Evanston, assignor to the Western Electric Company, Chicago, Ill. Filed Dec. 10, 1888.

511,512. Machine for Separating Magnetic from Non-Magnetic Substances. George G. Crosby, New York, N. Y., assignor to the Magnetic Iron Milling Company of Tennessee. Filed Jan. 11, 1893.

511,514. Process of and Composition for the Manufacture of Porous Cups for Electrical Batteries. Frank G. Curtis, Philadelphia, Pa. Filed Feb. 13, 1893.

511,547. Electric Wire Covering. Franklin S. Randall, Philadelphia, Pa. Filed June 2, 1893.

511,574. Electric Transformer. James J. Wood, Fort Wayne, Ind. Filed May 19, 1893.

511,682. Electrolyzing Apparatus. Antoine J. O. Chalandre, Paris, France, assignor to the Society Outhenin Chalandre Fils et Cie, same place. Filed Sept. 13, 1893.

511,731. Electric Signaling Apparatus. Thomas B. Doolittle, Bridgeport, Conn. Filed Feb. 13, 1893.

511,742. Electric Cautery Apparatus. James A. Wotten and Earnest A. Bostrom, Atlanta, Ga. Filed June 26, 1893.

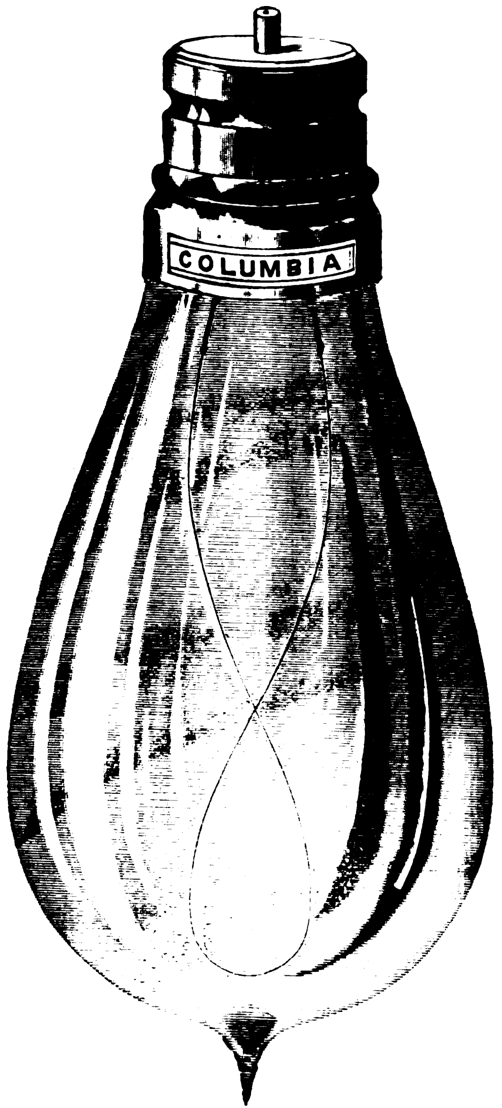
COLUMBIA

INCANDESCENT LAMPS.

UNEQUALLED IN QUALITY.



This "Incandescent Lamp Lawfully Made."

The **ONLY STRICTLY HIGH-GRADE INCANDESCENT LAMP MANUFACTURED** in the United States, under and by authority of Court, by a decision rendered in our favor on the 21st day of April, 1893.

By reason of the magnificent support which has been given this Company during the past year, and especially since the

Decision in our favor denying an Injunction

applied for by the Edison Company, we have been enabled to largely increase our manufacturing facilities, which has been the means of bringing about a REDUCTION in the PRICE OF INCANDESCENT LAMPS, thereby giving all users the benefit of our splendid victory over the TRUST.

We shall therefore make a REDUCTION in the PRICE OF INCANDESCENT LAMPS, to take effect on and after January 10, 1894. Price List will be furnished upon application.

At the same time we shall maintain the

HIGH STANDARD OF THE COLUMBIA LAMP,

and shall always keep pace with any improvements that may be made. Our Lamps will be found to be the MOST UNIFORM in general results of any now offered to the Trade. They are LONG-LIVED, EFFICIENT, AND WILL MAINTAIN THEIR CANDLE POWER to the highest degree.

Our POLICY in regard to PATENT LITIGATION and PROTECTION to USERS has been outlined during the past month in the Electrical journals.

We solicit your orders on the MERIT of the goods which we produce as well as on the policy which has been heretofore outlined.

WHY NOT REDUCE YOUR COAL BILL?

YOU CAN DO IT BY USING OUR "394" COMPOUND.

It has proven to be of great commercial value to others, and would be to you if you will try it.

Tabulated statements made by experts of the amount of water evaporated by steam boilers throughout the United States with coal in its natural state show an average of only 7¼ pounds of water evaporated with one pound of coal. The average tabulated results from the use of coal treated with "**394**" show that 11¼ pounds of water are evaporated with one pound of coal.

"394" promotes and quickens combustion of coal.
" reinforces the fire.
" produces a higher temperature.
" generates more steam.
" consumes the smoke or free carbon.
" increases the horse-power of boilers.
" prevents the formation of clinkers.
" makes one-third less ashes.
" saves grate bars.
" keeps the flues clean.
" displaces blowers.
" reduces the labor of firemen.
" saves from 10 to 30 per cent.
" requires no alteration in the fire-box.

Testimonials come from all parts of the country and are in every case spontaneous.

A series of tests were made at the suggestion of the Editor of *Power* by Prof. R. C. Carpenter, at Cornell University, and the Editor has this to say as the result in June number, 1892.

For the outcome of these tests, as set forth in the subjoined report, we confess that we were entirely unprepared If it is an actual fact, as is here set forth after a series of careful tests at one of the most reputable engineering institutions in the world, by a professor of that institution, that a saving of from 7 to 16 per cent. is to be effected by so simple an expedient, it is a matter of which our readers will be glad to be advised.

The North-Western Land and Coal Company is prepared to furnish "394" in large or small quantities as may be required, and full particulars as to price, quantity and directions for use can be obtained at their offices. Terms and prices will be mailed to large consumers, manufacturing industries, railroads, steamboats and corporations. The attention of all parties interested in reducing their fuel bills, **abating smoke and increasing power**, is called to the many advantages presented by the use of our "394" coal saving and smoke consuming compound.

Further information can be obtained at the General Offices, or at any of its branches, or through its authorized Agents.

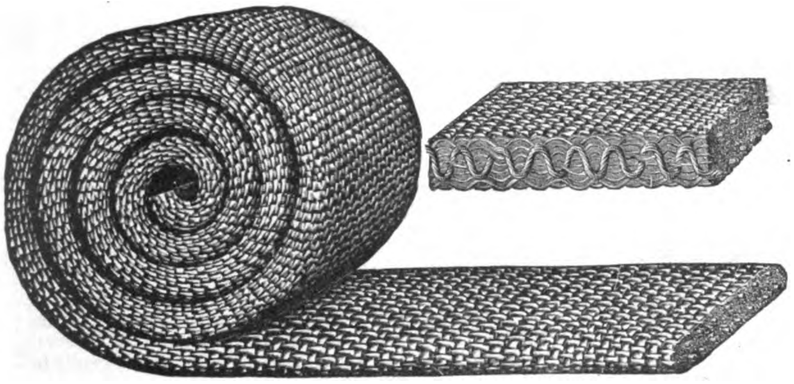
THE MADDOX COTTON AND WIRE BELTING.

Made of Cable Steel Wire and Cotton Woven Solid Together.



Is absolutely the strongest, toughest, most powerful, flexible, durable and lasting belting made, without any exception whatever. It is stronger, tougher, more durable, and will transmit more power than the best oak tanned double leather belting made. It will not stretch or slip, even when wet. Ia is waterproof and is not affected any by water, steam, dampness, moisture, heat, dryness, oils, grease, acids, chemicals, dust, changes of climate or weather. It will not mildew, crack, or get hard or stiff. Does not require any grease or other belt compositions nor special care, but will always keep soft and flexible and in good condition for use. It is cheaper in price than sinlge leather belting, and 50 to 75 per cent. cheaper than double leather belting. It is absolutely superior to all other kinds of belting for dynamo-electric power and light plants, and all places where belting of any kind is used.

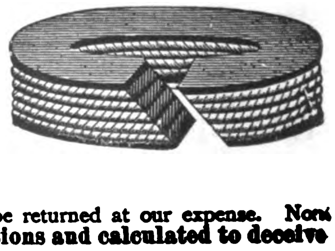
TRADE MARK.



NEW BOOKS.

SECOND EDITION, JUST ISSUED.

Revised. Enlarged. Entirely Rewritten.

A DICTIONARY OF ELECTRICAL WORDS, TERMS AND PHRASES,

By EDWIN J. HOUSTON, A.M.

562 Large Octavo Pages. 570 Illustrations. Price, $5.00.

Some idea of the scope of **this timely and important work** and of the immense amount of labor involved in it, may be formed when it is stated that it contains definitions of about **5,000** DISTINCT WORDS, TERMS OR PHRASES.

The Dictionary is not a mere word book. The words, terms and phrases are invariably followed by a **short, concise definition**, giving the sense in which they are correctly employed and a general statement of the **principles of electrical science** on which the definition is founded.

As one feature, an elaborate system of **cross references** has been adopted, so that it is as **easy to find the definitions** as the words, and aliases are readily detected and traced.

The **typography is excellent**, being large and bold, and so arranged that **each word catches the eye at a glance** by standing out in sharp relief from the page.

ALTERNATING CURRENTS OF ELECTRICITY:

Their Generation, Measurement, Distribution and Application.

By Gisbert Kapp, M.I.C.E., M.I.E.E.

With an Introduction by William Stanley, Jr.

Cloth. 164 Pages, 37 Illus., 2 Plates. $1.00.

This volume explains in clear, simple language the theory of alternating currents and apparatus, particular attention being paid to transformers and multi-phase currents and motors.

The treatment is entirely a practical one, the descriptions noting the various advantages and defects of different types, and the sections devoted to designing containing the practical data and instructions required by the engineer.

CONTENTS.

Introduction, by William Stanley, Jr. Chap. I. Introductory Chap. II. Measurement of Pressure, Current and Power. Chap. III. Conditions of Maximum Power. Chap. IV. Alternating Current Machines. Chap. V. Mechanical Construction of Alternators. Chap. VI. Description of Some Alternators. Chap. VII. Transformers. Chap. VIII. Central Stations and Distribution of Power. Chap. IX. Examples of Central Stations. Chap. X. Parallel Coupling of Alternators. Chap. XI. Alternating Current Motors. Chap. XII. Self-Starting Motors. Chap. XIII. Multi-phase Currents.

The Electric Railway IN THEORY AND PRACTICE.

By O. T. CROSBY and Dr. LOUIS BELL.

Second Edition. Revised and Enlarged.

416 Octavo Pages, 182 Illus. Price, $2.50.

This is the first SYSTEMATIC TREATISE that has been published on the ELECTRIC RAILWAY, and it is intended to cover the GENERAL PRINCIPLES OF DESIGN, CONSTRUCTION AND OPERATION.

TABLE OF CONTENTS:

Chapter I. General Electrical Theory.
" II. Prime Movers.
" III. Motors and Car Equipment.
" IV. The Line.
" V. Track, Car Houses, Snow Machines.
" VI. The Station.
" VII. The Efficiency of Electric Traction.
" VIII. Storage Battery Traction.
" IX. Miscellaneous Methods of Electric Traction.
" X. High Speed Service.
" XI Commercial Considerations.
" XII. Historical Notes.

APPENDICES:

Appendix A. Electric Railway vs. Telephone Decisions.
" B. Instructions to Linemen.
" C. Engineer's Log Book.
" D. Classification of Expenditures of Electric Street Railways.
" E. Concerning Lightning Protection, by Prof. Elihu Thomson.
" F. Motors with Beveled Gear, and Series Multiple Control of Motors.
" G. Method of Measuring Insulation Resistance of Overhead Lines,

The Measurement of Electrical Currents And Other Advanced Primers of Electricity.

By Prof. Edwin J. Houston, A.M.,

AUTHOR OF

"A Dictionary of Electrical Words, Terms and Phrases,"
"Electricity and Magnetism, Being a Series of Advanced Primers."

Cloth. 320 pages. 120 Illustrations. Price, $1.00.

This volume is the second of Prof. Houston's admirable series of Advanced Primers of Electricity and is devoted to the measurement and practical applications of the electric current.

Marked features of these books are the logical and lucid development of principles in language easily followed with no previous knowledge of electricity, and the abstracts from standard electrical authors at the end of each Primer, which in general have reference, and furnish an extension, to some point in the Primer, and at the same time give the reader an introduction to electrical literature.

CONTENTS.

I. The Measurement of Electric Currents. II. The Measurement of Electromotive Force. III. The Measurement of Electric Resistances. IV. Voltaic Cells. V. Thermo-Electric Cells and Other Electric Sources. VI. The Distribution of Electricity by Constant Currents. VII. Arc Lighting. VIII. Incandescent Electric Lighting. IX. Alternating Currents. X. Alternating Current Distribution. XI. Electric Currents of High Frequency. XII. Electro-Dynamic Induction. XIII. Induction Coils and Transformers. XIV. Dynamo Electric Machines. XV. Electro-Dynamics. XVI. The Electro-Motor. XVII. The Electric Transmission of Power. XVIII. Review: Primer of Primers.

ORIGINAL PAPERS ON DYNAMO MACHINERY AND ALLIED SUBJECTS.

By JOHN HOPKINSON, F.R.S.

Uniform with Thompson's "Lectures on the Electromagnet."

Cloth. 247 pages. 98 Illustrations. Price. $1.00.

This collection of papers includes all written on electro-technical subjects by the distinguished author, most of which have been epochal in their character and results.

The papers are arranged according to subject. Five papers relate wholly or in part to the continuous current dynamo; four are on converters and one each on the theory of alternating current machines and on the application of electricity to light-houses.

In the words of the author "The motive of this publication has been that I have understood that one or two of these papers are out of print and not so accessible to American readers as an author who very greatly values the good opinion of American electrical engineers would desire."

ELECTRICITY AND MAGNETISM

A Series of Advanced Primers,

By Prof. EDWIN J. HOUSTON,

AUTHOR OF

"A Dictionary of Electrical Words, Terms and Phrases."

Cloth. 306 pages. 116 Illustrations. Price, 1.00.

Prof. Houston's Primers of Electricity written in 1884 enjoyed a wide circulation, not only in the United States, but in Europe, and for some time have been out of print. Owing to the great progress in electricity since that date the author has been led to prepare an entirely new series of primers, but of a more advanced character in consonance with the advanced general knowledge of electricity.

Electricians will find these primers of marked interest from their lucid explanations of principles, and the general public will in them find an easily read and agreeable introduction to a fascinating subject.

CONTENTS.

I.—Effects of Electric Charge. II.—Insulators and Conductors. III.—Effects of an Electric Discharge. IV.—Electric Sources. V.—Electro-receptive Devices. VI.—Electric Current. VII.—Electric Units. VIII.—Electric Work and Power. IX.—Varieties of Electric Circuits. X.—Magnetism. XI.—Magnetic Induction. XII.—Theories of Magnetism. XIII.—Phenomena of the Earth's Magnetism. XIV.—Electro-Magnets. XV.—Electrostatic Induction. XVI.—Frictional and Influence Machines. XVII.—Atmospheric Electricity. XVIII.—Voltaic Cells. XIX.—Review, Primer of Primers.

SENT POSTPAID ON RECEIPT OF PRICE.

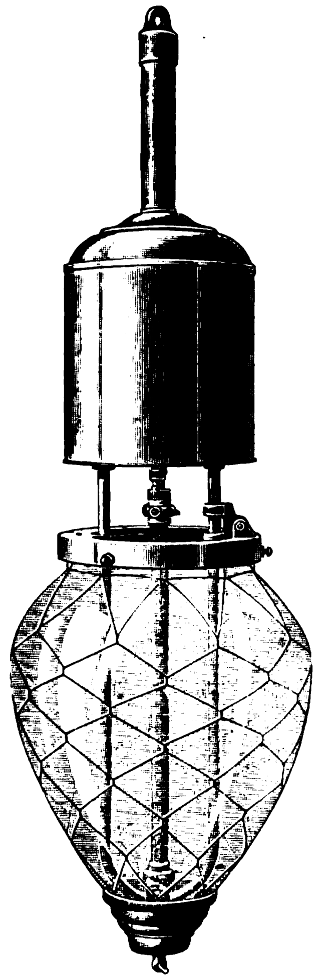
6 Park Place, N. Y. City.



ARC LAMPS
FOR ALTERNATING CIRCUITS

We are just placing on the market an Arc Lamp for alternating circuits, either 30 or 50 volts, secondary. This lamp is exceedingly simple in construction and positive in its action, reducing to a minimum the liability to get out of order. It is constructed throughout of the very best material. The light from the arc is perfectly steady.

We make them at present in two sizes, 10 and 14 amperes.

The lamp is thoroughly weatherproof without the use of a hood, and is especially designed to facilitate the work of trimming and cleaning the globe, so that one man can trim and attend to twice as many of these lamps as of the ordinary pattern. The total weight of the lamp, including globe and all fittings, is fifteen pounds.

The first cost of this lamp is very reasonable, and we shall be pleased to hear from central stations desiring an alternating arc lamp that will give satisfaction to their customers, and prove a profitable investment.

At very slight additional cost the lamp can be made in various ornamental designs

We also have a full line of Arc Lamps for constant potential circuits, street railway circuits, etc., etc.
